Novo argues that the terms standard insulin needle fitting and standard mounting in the claim language "[a] standard insulin needle fitting for removably mounting said needle assembly on a pen-type syringe having a standard mounting" 1 are unambiguous.
Novo argues that the term "standard" is defined as "regulatory and widely used, available, or supplied." Merriam-Webster's College Dictionary, 1145 (10th ed. 1998). According to Novo "standard insulin needle fitting" plainly refers to needle fittings which are commonly used on pen-type insulin delivery devices.

Further, it argues that the significance of the term "standard" is evident when the claim is construed as a whole. Novo contends that in claim 1 of the '323 patent, the structure of the needle hub is defined with reference to an unclaimed object, namely, a pen syringe. In its view, without the term "standard," a person skilled in the art would be unable to ascertain the structure of the needle hub, and thus the claim would be vague, because a pen syringe could potentially be designed to accommodate any needle hub. The word "standard" allows persons skilled in the art to understand the scope of the claim with reasonable clarity, because a person skilled in the art would know what needle hubs are standard at any given time.

Becton submits that the limitations "standard insulin needle fitting" and "standard mounting" had no discernible meaning for one of ordinary skill in the art when Novo's Danish application was filed in 1991. At that time, it contends, there was neither a de facto standard needle nor an industry-accepted standard for pen needles. To support its contention, Becton cites statements of Frits Bonnichsen, Novo's co-inventor in charge of the development of the 30 gauge pen needle. See (Sharrott Decl., Exh. 13, at 125-126.) In addition, Becton argues that there is no basis whatsoever for construing the terms "standard" fitting and "standard" mounting. In its view, there is no description of a standard fitting or mounting that at the time of the alleged invention would convey with reasonable clarity to one skilled in the art that the inventors were in possession of the claimed needle assembly inventions.

At the Court's Markman hearing, Novo argued the following: (1) that the "standard" limitations first appeared in July 1996 when Claims 1-4 were added to Novo's '323 patent application by amendment; (2) that "standard" does not reflect an industry or government standard; 2 (3) that there could be more than one "standard"; and (4) that while the drawings submitted in support of Novo's patent application are examples of a "standard," the standard can change over time. See March 6, 2000 Tr. at 5-11.

It is quite clear that after examining the intrinsic evidence--the claim language and the prosecution history--and the extrinsic evidence, 3 this Court cannot determine what "[a] standard insulin needle fitting for removably mounting said needle assembly on a pen-type syringe having a standard mounting," was at the time of the patent. The Court can and does construe the word standard in accordance with the dictionary definition of standard to mean: "regularly and widely used, available, or supplied." Again, as to what needle fittings and mountings were "regularly and widely used, available, or supplied," at the time of the patent, this Court assumes that the parties will adduce proof on this point at trial on the issue of infringement.

It is quite clear that after examining the intrinsic evidence--the claim language and the prosecution history--and the extrinsic evidence, 3 this Court cannot determine what "[a] standard insulin needle fitting for removably mounting said needle assembly on a pen-type syringe having a standard mounting," was at the time of the patent. The Court can and does construe the word standard in accordance with the dictionary definition of standard to mean: "regularly and widely used, available, or supplied." Again, as to what needle fittings and mountings were "regularly and widely used, available, or supplied," at the time of the patent, this Court assumes that the parties will adduce proof on this point at trial on the issue of infringement.

The parties dispute the construction of a term in claims 1 and 8 of the '196 patent comparing the dimension of the claimed needle cannula with "the standard needle cannula," of various gauges. Ideal asserts that no construction of this unambiguous

i. Arguments of the parties. Rivard contends that the word "standard" was added to the patent by amendment to distinguish prior art and that, to make this amendment, the patentee represented that the dimensions listed in an exhibit, found in the Joint Appendix at 787-88, were "standard" dimensions of needles of various gauges. Rivard contends that Ideal is now bound by this exhibit as defining "standard" gauges for "standard" needles. Notwithstanding its prior argument that "gauge" is determined only by reference to outer diameter, Rivard now argues that the claimed needle must be compared to the outside and inside diameters of a single gauge size "standard" needle, so that the claimed needle is not compared to the outside diameter of one gauge size and the lumen diameter of a different gauge size. Rivard also notes that, while the specification refers to "prior art needles," the specification references "standard" dimensions only once, as follows: "The standard 16 gauge needle used for injecting animal health products into an animal is about 19.0 mm in length." The '196 patent, Col. 8, ll. 16-18. Rivard points out that the specification compares prior art needles of a certain gauge with the represented gauge size number of the claimed needle, not the actual gauge size number of the claimed needle based on outer diameter. Rivard also points out that the prosecution history reveals that the patentee represented the dimensions in the exhibit provided to the examiner as "the" standardized dimensions, rather than as 'a' set of dimensions among possible alternatives, and then compared the "standard" dimensions of a prior art needle of a certain gauge to the dimensions of the claimed needle of a represented gauge, arguing that the inventive aspect was thicker sidewalls. Absent the exhibit of "standardized" dimensions, Rivard argues that the claims would have been rejected as providing insufficient description, definiteness, or enablement.

Ideal counters that, notwithstanding the amendment of the claims to refer to "standard" needles of certain gauges, the claim term in question requires no construction, because it is unambiguous. Ideal contends that the patentee used the exhibit of needle dimensions to which Rivard claims the patent must now be restricted to illustrate the patentee's contention that needle dimensions for various gauges are standardized, but did not thereby restrict itself to the dimensions in the exhibit as constituting "the" standard dimensions. Instead, Ideal argues that, within the context of the '196 patent and its prosecution history, a person of ordinary skill in the art would understand the embodiments and the dimensions for syringe needles stated in the exhibit to be merely exemplary in nature. Ideal also contends that Rivard's references to the "represented" gauge of the claimed needle are not supported by any evidence, intrinsic or extrinsic. Likewise, Ideal argues that Rivard's use of "corresponding gauge" is improper, because the patentee amended out the phrase "of identical gauge." Ideal also contends that the plain language of the patent claims and the prosecution history belie Rivard's construction, because they make clear that what Rivard relies on is an illustration, not a disavowal of any claim scope.

In its rebuttal brief, Rivard focuses again on the meaning of "standard" needle gauges, asserting that Chimie v. PPG Industries, Inc., 402 F.3d 1371 (Fed. Cir. 2005), demonstrates that the sole evidence upon which Ideal relied to show
"standard" needle gauge dimensions, the exhibit of dimensions submitted to the examiner, limits the claims of the '196 patent to the dimensions in that exhibit. In its rebuttal brief, Ideal, likewise, focuses on this contention, reiterating that the prosecution history demonstrates that the patentee did not restrict the scope of this patent claim term to the exhibit on which Rivard relies, but that exhibit only to illustrate the fact that standardized needles are generally known in the art. Ideal also reiterates in its rebuttal brief that there is no basis on which to assert that the comparison at issue is between a claimed needle "represented to be a gauge" and "standard" needles illustrated in the exhibit on which Rivard relies.

ii. Analysis. The court has already construed the term "gauge" in the same claims of the '196 patent to mean the following: "A size measurement of needles determined by the outer diameter and the inner or lumen diameter." The parties' arguments concerning the claim term now at issue suggest the parties' recognition that, at least for purposes of the '196 patent, "gauge" is determined by both the outer diameter and the inner or lumen diameter. Moreover, looking first at the words of the patent claims, see Nystrom, 424 F.3d at 1142 (courts must "begin [their] claim construction analysis with the words of the claim"), it is apparent that the comparisons being made between the claimed needle and "the standard needle cannula" are, likewise, between the outer diameter (claimed to be "greater" for the claimed needle) and the inner or lumen diameter (claimed to be "identical to a lumen diameter of the standard needle cannula"), and hence, the claimed needle has a thicker sidewall. See also '196 patent, claim 1, Col. 9, ll. 4-12 (explaining that the claimed needle cannula has a sidewall thickness that increases detectability over standard needle cannulas). The claim language reveals that this comparison applies to "standard needle cannula between 14 and 27 gauge," so that the embodiment of the claimed needle in each gauge would have the same lumen diameter as a "standard needle cannula" in that gauge, but a greater outer diameter. The question is whether the points of reference, "the standard needle cannulas" of certain gauges, against which the claimed needle cannulas are compared, have been specifically limited to the dimensions stated in the exhibit that accompanied the patentee's assertion that dimensions of needle gauges are "standardized." Nothing in the claim language answers that specific question.

Therefore, the court turns to the specification for guidance. See Aquatax, 419 F.3d at 1380 ("Where . . . the disputed claim term is technical or a term of art, [t]he best source for understanding [it] is the specification from which it arose, informed, as needed, by the prosecution history.") (quoting Phillips, 415 F.3d at 1315); Phillips, 415 F.3d at 1314 (the specification is not only "highly relevant" to claim construction, "[u]sually, it is dispositive," and "is the single best guide to the meaning of a disputed term"). The first portion of the Detailed Description that is pertinent to interpretation of the claim term presently before the court is the following:

"In the case of the 16 gauge embodiment of the needle of the present invention, the sidewalls 17 flanking (opposite each other) the lumen 18 have a combined thickness which is greater than 0.46 mm (0.018 inch), preferably a combined thickness of 0.64 mm (0.025 inch) and the diameter of lumen 18 is about 1.19 mm (0.047 inch). Thus, the outer diameter of needle 12 is about 1.8 mm (0.072 inch). Preferably, the needle cannula of the present invention has a circular cross-section. In contrast, a 16 gauge prior art needle has an outside diameter of about 1.65 mm (0.065 inch) and a lumen diameter of about 1.19 mm (0.047 inch). Therefore, the combined thickness of the sidewalls flanking (opposite each other) the lumen of the prior art needle is about 0.46 mm (0.018 inch), which is somewhat more likely to break. . . ."

While the 16 gauge embodiment is shown herein, the needle cannula of the present invention includes needle cannulas of other gauges and needle assemblies comprising needle cannulas of other gauges. For example, needle cannulas that are useful for medical and veterinarian purposes generally include those gauges within the range 14 to 26. Thus, the needle cannula of the present invention includes, but is not limited to, gauges between 14 and 27. It should be understood that because the sidewall of the needle cannula of the present invention is thicker than the sidewall of prior art needle cannulas and the outer diameter of the needle cannula determines the gauge, a 16 gauge needle cannula of the present invention has an outer diameter similar to the outer diameter of a 15 gauge needle cannula.

The '196 patent, Col. 4, l. 55, to Col. 5, l. 26. This portion of the Detailed Description confirms not only that the points of comparison for an embodiment of the claimed needle of a certain gauge and "prior art" needle cannulas of the same gauge are the outside diameter and the inside or lumen diameter, but that the outside diameter of the embodiment of the claimed needle of that gauge is greater. This portion of the specification also clarifies that the claimed needle is not "represented to be" of a certain gauge; rather, an "embodiment" of the claimed needle of a certain gauge has a greater outer diameter than the "prior art" needle cannula of the same gauge, but the same inner or lumen diameter. Finally, this portion of the specification strongly suggests that a 16 gauge "standard needle cannula" has an outside diameter of about 1.65 mm (0.065 inch) and a lumen diameter of about 1.19 mm (0.047 inch), although the Description is cast in terms of "a 16 gauge prior art needle," rather than "a 16 gauge standard needle." A person of ordinary skill in the art is likely to understand that "prior art
The paragraph bridging pages 8-9, illustrates the difference in wall thickness between the applicant's 16 gauge needle in the exhibit as representing "standardized" dimensions. This is so, because the patentee asserted the following:

illustrate that gauges for syringe needles are standardized, not to disclaim any dimensions of gauges other than those shown
Joint Appendix at 772 (emphasis added). The prosecution history also reveals that the patentee used the exhibit at issue to
standard needle of the prior art has an outside diameter of about 0.065 inches and a lumen diameter of about 0.047 inches."

is so, because the patentee's Reply To Office Action of February 3, 2003, expressly states, "For example, the 16 gauge
with "prior art needle," as stated in the first portion of the Detailed Description discussing needle gauge quoted above. This

Thus, in order to detect a length of a stainless steel 16 gauge prior art needle cannula, which has a diameter of about 1.65
mm, the length of the needle that is embedded in the flesh of the animal must be at least about 8 mm to be detected free of
orientation effects at a sensitivity of 1.5 mm or at least about 24 mm to be detected free of orientation effects at a sensitivity
of 2.0 mm. The standard 16 gauge needle used for injecting animal health products into an animal is about 19.0 mm in
length.

In contrast, the length of the magnetized heavy duty stainless steel needle cannula of the present invention that can be
detected free of orientation effects at a sensitivity of 1.5 mm and 2.0 is about 7.0 mm. and 21.0 mm, respectively.

The '196 patent, Col. 8, ll. 10-23. This portion of the Detailed Description refers to both a "16 gauge prior art needle
cannula" and a "standard 16 gauge needle," suggesting that the two terms are synonymous.

At best, however, the Detailed Description suggests the "standard" dimensions of only a 16 gauge "standard needle
cannula." Thus, the court turns to the prosecution history to see what it reveals. See Nystrom, 424 F.3d at 1142 ("In addition
to the written description, the prosecution history can often inform the meaning of the claim language by demonstrating
how the inventor understood the invention and whether the inventor limited the invention in the course of prosecution,
making the claim scope narrower than it would otherwise be.") (quoting Phillips, 415 F.3d at 1317); Research Plastics, 421
F.3d at 1296 ("The purpose of consulting the prosecution history in construing a claim is to "exclude any interpretation that
was disclaimed during prosecution.") (quoting Rhodia Chimie, 402 F.3d at 1384, in turn quoting ZMI Corp., 844 F.2d at
1580). The prosecution history reveals that, in the exhibit provided by the patentee showing "Syringe Needle Dimensions,"
Joint Appendix at 787-88, the outside diameter of a 16 gauge needle is, indeed, shown as 1.651 mm (0.0650 inch), or "about
1.65 mm (0.065 inch)," as stated in the Detailed Description, and the inner or lumen diameter is shown as 1.194 mm (0.047
inch), or "about 1.19 mm (0.047 inch)," as stated in the Detailed Description. 18 Thus, there is a correlation between the
dimensions of a 16 gauge needle, as shown in the exhibit, and the 16 gauge "prior art needle" described in the Detailed
Description. This is a long way, however, from evidence that the patentee intended to or did exclude any interpretation of
"standard" needle dimensions during prosecution other than an interpretation based on the exhibit simply by offering the
exhibit in the course of prosecuting the patent. See Research Plastics, 421 F.3d at 1296 ("The purpose of consulting the
prosecution history in construing a claim is to "exclude any interpretation that was disclaimed during prosecution.")
(quoting Rhodia Chimie, 402 F.3d at 1384, in turn quoting ZMI Corp., 844 F.2d at 1580).

18 Again, to be precise, the exhibit shows the nominal inside diameter of a 16 gauge syringe needle to be 0.470 inch, but
that is clearly a misprint, based on the conversion of the stated nominal inside diameter of a 16 gauge needle from
millimeters (stated as 1.194) to inches (0.047 inch), and the stated nominal inside diameters for 15 and 17 gauge needles
(0.0540 inch and 0.0420 inch, respectively). See Joint Appendix at 787.

Other portions of the prosecution history shed more light on what was meant by "standard needle cannulas" and the role that
the exhibit played in the prosecution history. The prosecution history demonstrates clearly that the patentee meant "standard
needle" to mean "standard needle of the prior art," i.e., to equate "standard needle cannula," as stated in the patent claim,
with "prior art needle," as stated in the first portion of the Detailed Description discussing needle gauge quoted above. This
is so, because the patentee's Reply To Office Action of February 3, 2003, expressly states, "For example, the 16 gauge
standard needle of the prior art has an outside diameter of about 0.065 inches and a lumen diameter of about 0.047 inches."
Joint Appendix at 772 (emphasis added). The prosecution history also reveals that the patentee used the exhibit at issue to
illustrate that gauges for syringe needles are standardized, not to disclaim any dimensions of gauges other than those shown
in the exhibit as representing "standardized" dimensions. This is so, because the patentee asserted the following:

The paragraph bridging pages 8-9, illustrates the difference in wall thickness between the applicant's 16 gauge needle
compared to a 16 gauge needle of the prior art. Support for the term "standard" with respect to prior art needle cannulas can be found on page 15, lines 28-30, which discusses the length of a "standard" 16 gauge needle for injecting animal health products into an animal. It is generally known in the art that the gauges for syringe needles are standardized. This is illustrated in the attached Exhibit A which shows the outer diameter, inner diameter, and sidewall thickness for syringe needles ranging from gauge 10 to gauge 33.

Joint Appendix at 774 (emphasis added). The examiner allowed the claim, as amended, thus indicating acceptance of the patentee's contention that needle gauges are "standardized," but not thereby binding the patentee to the exhibit illustrating standardized dimensions for needles of various gauges.

Although Rivard argues that Chimie v. PPG Industries, Inc., 402 F.3d 1371 (Fed. Cir. 2005), is on point and requires the court to construe "standard" needles of various gauges to have the dimensions set out in the exhibit submitted by the patentee, the court does not agree. In Chimie, the court reviewed claim construction for a patent for essentially spheroidal precipitated silica particles and the process for manufacturing them. Chimie, 402 F.3d at 1374. The specification of the patent contained examples of silica products and the results of several tests making comparisons among those products, including "flowability" and "dusting properties." Id. The specification described a test of the level of dust formed by the various silica particulates, including a test using the DIN 53 583 standard, based on a German standard to measure certain physical properties of carbon black by determining the fines (dust) and weight loss by abrasion according to a defined procedure. Id. at 1374-75. The court construed the claim term "dust-free and non-dusting" to mean "a level of dust formation associated with the silica particulates of the [patent in suit], as measured in percentage weight according to DIN 53 583, that has a fines content value less than or equal to 13 and weight loss by abrasion value less than or equal to 0.5." Id. at 1375. In doing so, the court concluded that the term was ambiguous, because it could not be read literally to mean that the invention creates no dust at all, but the patentee's proffered definition, "very low dust," was a relative phrase that would not meet the standards of 35 U.S.C. § 112 P 2 that a patent claim must "particularly point out and distinctly claim the subject matter which the applicant claims as his invention." Id. Therefore, "[i]n order to resolve the perceived ambiguity of the claim term in a manner that preserved the term's validity, the court adopted 'a construction based upon the only meaningful guidance provided in the patent,' namely the DIN test." Id. (quoting the decision below).

On appeal, the Federal Circuit Court of Appeals found that, of the ten examples of silica products referenced in the written description, Example 5 was repeatedly described as the invention itself. Id. at 1378. The appellate court also found that the only measurement of the dust produced by Example 5 was articulated in terms of the DIN 53 583 standard, so that the district court properly incorporated that articulation into its construction of the term "dust-free and non-dusting." Id. The appellate court concluded that the reference to the DIN test results for Example 5, as provided in the written description of the patent, reconciled the ambiguous claim language with the inventor's disclosure and, as such, did not contravene the basic teaching that limitations from the specification should not be imported to the claims. Id. The court also concluded that this construction was consistent with the proposition that, when the preferred embodiment is described in the specification as the invention itself, the claims are not necessarily entitled to a scope broader than that embodiment. Id. at 1379 (citing Modine Mfg., 75 F.3d at 1551. Although the patentee identified alternative means for assessing the dust production of a product, the appellate court found that the only articulation of the dustiness of the claimed invention was made with reference to the DIN 53 583 standard. Id. at 1379-80. Therefore, the court concluded as follows:

[The patentee] chose to define the term "dust-free and non-dusting" solely by reference to characteristics of the prior art and the only comparison of those characteristics was explained according to the DIN 53 583 standard. It was not improper for the district court to limit the scope of this relative term to the only disclosure on the subject made in the patent.

Chimie, 402 F.3d at 1380.

The circumstances here are distinguishable. First, unlike the patent at issue in Chimie, the claims and the specification of the '196 patent do not make any reference to the exhibit illustrating "standard" needle dimensions on which Rivard relies. See id. at 1374-75 & 1378. Instead, the exhibit is only found in the prosecution history of the '196 patent where the court found, above, that it only illustrates the patentee's contention that "[i]t is generally known in the art that the gauges for syringe needles are standardized." Joint Appendix at 774. Second, while the claim term at issue here may be "relative," as was the disputed claim term in Chimie, the "relative" term in the '196 patent is not ambiguous for lack of a comparator, as was the case in Chimie, where the dimensions of the claimed needle are expressly compared to the dimensions of "standard" needles of the same gauge. Compare id. at 1375 & 1380. The comparator in the '196 patent, a "standard" needle, is not itself
embodiment of a 22s gauge needle, because only as an embodiment of a 25s gauge needle would it satisfy the claim diameter of 0.0055 inch, while a 25s gauge needle has an outer diameter of 0.0200 inch and an inner diameter of 0.0055 inch as compared to the exhibit showing a 22s gauge needle has an outer diameter of 0.0280 inch and an inner diameter of 0.0055 inch. 20 Rivard makes a similar argument concerning a needle with an outer diameter of 0.0280 inch and an inner diameter of 0.0095 inch as compared to the exhibit showing a 25 gauge needle has an outer diameter of 0.0200 inch and an inner diameter of 0.0095 inch, which would result in a lumen diameter of approximately 0.047 inch (0.065 - 0.009 = 0.047, where the thickness of the sidewall on both sides of the lumen must be subtracted), which is also consistent with the patentee's exhibit. Thus, there is absolutely no evidence in the record to rebut the patentee's contention in the prosecution history that "[i]t is generally known in the art that the gauges for syringe needles are standardized." Joint Appendix at 774.

Thus, in light of the intrinsic evidence, the court tentatively construed the term in question to mean the following: "For an embodiment of the claimed needle cannula between 14 and 27 gauge, the outer diameter is greater than the outer diameter of the standard needle cannula of the prior art of the same gauge and the lumen diameter is identical to the lumen diameter of the standard needle cannula of the prior art of the same gauge."

At the Markman hearing, Rivard took issue with this construction on two grounds. First, Rivard contended that the claimed needle must be construed to be "represented to be" of a certain gauge, not simply to be "an embodiment" of a certain gauge. Rivard argues, for example, that a needle with outer diameter of 0.0200 inch and inner diameter of 0.0095 inch may not meet the court's tentative construction if called a "25 gauge," but might meet the court's tentative construction if called a "26 gauge," where the exhibit offered by the patentee as illustrating standardized needle dimensions, Joint Appendix 787, indicates that a 25 gauge needle has an outer diameter of 0.0200 inch and an inner diameter of 0.0095 inch, but a 26 gauge needle has an outer diameter of 0.0180 inch and an inner diameter of 0.0095 inch. Perhaps the court simply misses Rivard's point, but a claimed needle with an outer diameter of 0.0200 inch and an inner diameter of 0.0095 inch presumably would not be an embodiment of a 25 gauge needle for the simple reason that not only is the inner or lumen diameter of such a needle identical to the inner or lumen diameter of a 25 gauge "standard" needle, at least as illustrated in Joint Appendix 787, but the outer diameter of such a needle is also identical to the outer diameter of a 25 gauge "standard" needle, rather than greater than the outer diameter of a 25 gauge "standard" needle, as claimed in the patent. Such a claimed needle could, however, be an embodiment of a 26 gauge needle, because it has a greater outer diameter than an outer diameter of a "standard" needle and an inner or lumen diameter that is identical to an inner or lumen diameter of a "standard" needle, as claimed in the patent. In other words, Rivard's perceived problem is simply resolved by reference to the claim language, and the court's construction of the pertinent claim term as an "embodiment" of the claimed needle of a certain gauge rather than a claimed needle "represented to be" of a certain gauge "stays true to the claim language and most naturally aligns with the patent's description of the invention."

Nystrom, 424 F.3d at 1142 (quoting Phillips, 415 F. 3d at 1316, in turn quoting Renishaw PLC, 158 F.3d at 1250). 20

20 Rivard makes a similar argument concerning a needle with an outer diameter of 0.0280 inch and an inner diameter of 0.0055 inch as compared to the exhibit showing a 22s gauge needle has an outer diameter of 0.0280 inch and an inner diameter of 0.0055 inch, while a 25s gauge needle has an outer diameter of 0.0200 inch and an inner diameter of 0.0055 inch. The answer is also the same: The needle in question could be an embodiment of a 25s gauge needle, but not an embodiment of a 22s gauge needle, because only as an embodiment of a 25s gauge needle would it satisfy the claim.
requirement that it have a greater outer diameter than a "standard" needle of the same gauge.

Next, Rivard reiterated at the Markman hearing its contention that the dimensions set forth in the exhibit at Joint Appendix 787-88 must be construed to be "the" standard dimensions of "standard" needles. Rivard contended that, otherwise, the public does not receive adequate notice of the "standards." Rivard is correct that in Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335 (Fed. Cir. 1998), the Federal Circuit Court of Appeals explained that "[n]otice is an important function of the patent prosecution process, as reflected by the statute itself." Digital Biometrics, Inc., 149 F.3d at 1347 (citing 35 U.S.C. § 112, P 2, and Warner-Jenkinson Co. v. Hilton Davis Chem. Co., 520 U.S. 17, 117 S. Ct. 1040, 137 L. Ed. 2d 146 (1997)). Nevertheless, the court reiterates its tentative conclusion, above, that the exhibit at Joint Appendix 787-88 was offered by the patentee to illustrate its contention that "[i]t is generally known in the art that the gauges for syringe needles are standardized," Joint Appendix at 774, not to indicate "the" standards for needle dimensions. The court also reiterates its tentative conclusion, above, that the reference to dimensions of "standard" needle gauges is the "meaningful guidance" for the comparison in the '196 patent that was lacking in Chimie in the absence of the reference to the DIN 58 583 standard in the patent at issue in that case. Chimie, 402 F.3d at 1375. Rivard apparently contends that the only "meaningful guidance" for what is meant by "standard" needles--and, hence, the only way that the public has adequate notice of those "standards"--is the patentee's exhibit. The court does not agree, in the absence of any evidence that the dimensions of "standard" needles are not actually "standardized," so that the "standard" is unknown or subject to genuine dispute, and Rivard still has not presented any evidence generating such a genuine dispute. To the contrary, Rivard's own evidence from the American Society of Testing Materials (ASTM), Defendants' Appendix at 38 (Defendants' Exhibit E), suggests that dimensions for needle gauges are, indeed, "standardized," as explained supra in note 19. To put it another way, the reference to "standard" needles is sufficient public notice of the comparator in the absence of any evidence that the dimensions of "standard" needles are not actually "standardized," are unknown, or are subject to genuine dispute.

iii. The court's construction. In light of the intrinsic evidence, the court construes the term in question to mean the following: "For an embodiment of the claimed needle cannula between 14 and 27 gauge, the outer diameter is greater than the outer diameter of the standard needle cannula of the prior art of the same gauge, and the lumen diameter is identical to the lumen diameter of the standard needle cannula of the prior art of the same gauge."

3778

4. "staple line buttress itself"

Synovis contends that no construction is necessary, but if the Court decides to construe "staple line buttress itself," the term should be construed as "portion of a first region of buttress material that is within the reinforced seal, and is the only material that remains in the body." (Joint Statement at 8; Tr. at 64.) Gore, on the other hand, asserts that the Court should construe this term as "the portion of the buttress material that is stapled between abutting terminal sections of tissue and remains in position within the body and forms the staple line buttress seal." (Id.)

Synovis contends that its construction accurately captures the meaning of the term while keeping the term in context of the claims, which refer to a region "adapted to serve as the staple line buttress itself." Synovis asserts that Gore's proposed construction adds unnecessary language and unsupported limitations. In particular, Synovis asserts that Gore's construction would require that the entirety of the first region stay in the body and that the buttress material be positioned between abutting terminal sections of tissue.

Gore asserts that staple line buttress is the portion of the buttress material that is stapled between abutting terminal sections of tissue and remains within the body to form the staple line buttress seal. In support, Gore cites to the specification. (See '748 Patent c. 3, 11: 40-42 ("including a first region adapted to remain in position within the body in order to serve as the staple line buttress itself"); c. 4, 11: 53-58 ("a circumferential flat, disc-like portion adapted . . . to ultimately be positioned between the abutted tissue sections . . . to serve as a staple line buttress"); c. 5, 11: 37-41 ("The buttress materials comprise a generally planar circumferential exterior region . . . to be positioned between the abutting sections of tissue in order for form a seal therebetween.").) Gore asserts that Synovis' proposed construction is incorrect by stating that only a "portion" of the first region remains in the body and that the specification indicates that portions other than the first region may remain in the
body.

For the reasons discussed above with respect to the "staple line buttress seal between joined tissue sections" term, the Court does not construe the term "staple line buttress itself" to require that the portion of buttress material be "stapled between abutting terminal sections of tissue." Consistent with the ordinary meaning of the claim terms and the specification, the Court construes the term as "portion of the buttress material that is within the reinforced seal."

2. "staple line buttress seal between joined tissue sections"

Synovis contends that no construction is necessary, but if the Court decides to construe the term, the term should be construed as "a reinforced seal between two joined sections of tissue, having both tissue and buttress material." (Joint Statement at 6.) Gore, on the other hand, asserts that the Court should construe this term as "seal formed by buttress material positioned between abutting terminal sections of the first and second tissue portions." (Id.)

Gore contends that its proposed construction captures the notion of reinforcement inherent in the term "staple line buttress" and reflects the concept of a buttress seal, which Synovis maintains is necessarily composed of both buttress and tissue. Gore argues that its proposed construction is based upon the plain language of the term, making clear that the seal specifically includes buttress material that is positioned between abutting sections of tissue.

Both parties' constructions provide for a seal between two sections of tissue. The parties' dispute centers on where the buttress material and tissue are located after the seal is formed. Synovis asserts that the tissue ends up between the two sections of the buttress material. (Tr. at 66.) Gore maintains that the asserted claims require the buttress material to be between the abutting terminal portions of the first and second tissue portions.

Gore contends that the specification demonstrates that the buttress material ends up between portions of tissue. For example, Gore relies on a portion of the Detailed Description, which explains that in an embodiment, the staple cartridge buttress has "a circumferential flat disc-like portion (26) adapted to be positioned upon the open face (34) of the staple cartridge component (12), and to ultimately be positioned between the abutted tissue sections (and adjacent to the anvil buttress disc-like portion (32)) in order to serve as a staple line buttress." (748 Patent c. 4, 11: 54-65.) The specification further explains that ":[t]he buttress materials comprise a generally planar circumferential exterior region . . . to be positioned between the abutting sections of tissue in order to form a seal therebetween." (Id., c. 5, 11: 37-41). In addition, Gore points to the portions of the specification describing the staple cartridge component "being adapted to retain and position a terminal section of the first tissue portion," (id., c. 5, 11: 7-8), and the stapler anvil component as "adapted to retain and position a terminal section of the second tissue portion." (Id., c. 5, 11: 17-20.) Gore maintains that the specification describes the terminal sections of the tissue portions as being positioned directly on the cartridge and anvil and, further, that the buttress material is positioned between the abutting sections of tissue.

Synovis contends that Gore's construction would improperly exclude all embodiments in the '748 Patent and render the claims inoperable. Synovis asserts that the buttress material in the '748 Patent is always depicted as abutting the staple and anvil components. (748 Patent FIGS. 1-3.) In addition, Synovis asserts that the tissue is always shown over the buttress material. (Id., FIGS. 4a-d.) Synovis further asserts that the buttress seal is between the sections of tissue to be joined (for example two sections of intestine), and not between abutting terminal ends of that tissue.

Synovis asserts that the portions of the Detail Description (primarily Column 4 of the '748 Patent) cited by Gore in support of the notion that the buttress material is in between the tissue refer only to FIG. 2 of the '748 Patent and that FIG. 2 represents an embodiment of the buttress material before the tissue is involved. (Tr. at 67.) Synovis asserts that Column 4 of the '748 Patent therefore describes the orientation of the components prior to the tissue becoming involved. Synovis argues that the portion of the specification that refers to the overall process of creating a seal, including the process when the tissue is involved, demonstrates that the terminal ends of the tissue portions become sandwiched between the buttress material. For example, Synovis points to the language of Column 6 of the '748 Patent, which refers to Figures 4a-4d. Figures 4a-4d illustrate the process for creating a seam. (Id., c. 6, 11: 11-14) "FIG. 4 shows a cross-section view of the overall process of creating a reinforced stapled connection for tubular tissue in four steps, from top to bottom, using a preferred embodiment.
of this invention.). Figures 4a-4c all show that the buttress material lies on the open face of both the stapler and the anvil components and that the tissue being sealed ends up in between portions of buttress material. 13

13 Gore asserts that the Court should not rely on Figure 4 because 4d is incorrect. Gore asserts that Figure 4d must be inaccurate because it depicts buttress material being removed that is not near the joined tissue sections. The portion of buttress material being removed, however, is specifically labeled "severed material." (748 Patent c. 6, 11: 44.) That there is not a label for the remaining buttress material does not mean that there is none or that the "severed material" is meant to encompass all of the buttress material.

The language of the claim term "staple line buttress seal between joined tissue sections," provides that the seal is between joined tissue sections. This is consistent with the specification, which explains that buttress material along with joined tissue sections make up the seal. For example, the Abstract of the '748 Patent explains that "[t]he buttress material is retained and provides an improved seal between the joined tissue sections." The Summary of the Invention reads in part: "to provide a first region of buttress material as a staple line buttress seal retained between joined tissue sections." (748 Patent c. 2, 11: 48-51.) According to the claim language and the specification, it is the seal that remains between the joined tissue sections (i.e., two sections of intestine).

The Court next looks to the specification. It is evident that the language in Column 6 of the '748 Patent and the illustrations of Figure 4 are most relevant to the construction of this term. As detailed above, this section of the specification demonstrates an embodiment where the buttress material lies on the open face of both the stapler and the anvil and that the tissue being sealed ends up between portions of buttress material. Gore's proposed construction--"seal formed by buttress material positioned between abutting terminal sections of the first and second tissue portions"--is at odds with this embodiment. Gore's proposed construction would require not only that portions of buttress material lie on the open face of the stapler and anvil components, but also that the portions of buttress material touch each other when the seal is formed. If this configuration were required by the claim language, there would be no way for the tissue to be involved with the seal. Therefore, the Court declines to adopt Gore's proposed construction. Instead, the Court construes the term as "a reinforced seal between two sections of tissue."

1. "staple seam"

Synovis contends that no construction is necessary, but if the Court decides to construe "staple seam," it should be construed as "a seam between two joined sections of tissue." (Joint Statement at 9.) 12 Gore, on the other hand, asserts that the Court should construe this term as "seam formed when tissue sections are joined with staples." (Id.) The Court concludes that the term "staple seam" is properly construed as a "seam formed when tissue sections are joined with staples."

12 Synovis originally proposed using the word "joint" instead of "seam," but abandoned that proposal during the Markman hearing. (Tr. at 64.)

a. "Surgeon's operating station"
Claim 1 of the '688 Patent discloses a "surgeon's operating station at which a surgical procedure is performed with a plurality of self-contained independently and simultaneously operable pieces of surgical equipment." '688 Pat. col.19 ll.41-43. Claim 10 also discloses a "surgeon's operating station at which a surgical procedure is performed." Id. at col.20 ll.47-48. The Parties treat these terms as having the same meaning. The Court will construe the terms accordingly.

The critical difference between the Parties' proposed constructions is the location of the "surgeon's operating station" within the operating environment. KSEA argues that it is "one or more locations within an operating environment at which a member of the surgeon's team controls surgical equipment." (Joint Sub. for Technical Demonstration H'g & Claim Construction H'g (D.E. 90) Ex. A, Joint Submission Regarding Proposed Constructions ("Proposed Constructions Chart") 1.) S&N argues that it is the "place within the sterile area of the operating environment where the surgeon and the surgical instruments are located during a surgical procedure." (Id.)

The Court rejects KSEA's proposed construction. KSEA essentially argues that the "surgeon's operating station" is any part of the operating environment at which any member of the surgical team controls surgical equipment. This proposed construction ignores the language the applicant used. Although a surgical team may be comprised of surgeons and other individuals, the claim uses the word "surgeon" to modify "operating station," and KSEA has not demonstrated why "surgeon" would be understood by one skilled in the art to also include a nurse or surgical technician.

Further, Claim 1 expressly states that the control heads, which are used to control the surgical equipment, are "located at a non-sterile area remote from the surgeon's operating station." '688 Pat. col.19 ll.43-44 (emphasis added). This language forecloses the possibility that the "surgeon's operating station" is any place from which a member of the surgical team controls the surgical equipment.

The Court also rejects KSEA's argument that Claim 1 expressly defines the "surgeon's operating station" as an "endoscopic operating environment." This aspect of Claim 1 is difficult to construe, but the Court declines to read it as saying that an "endoscopic operating environment" is a "surgeon's operating station." Cf. Edward Lifesciences LLC v. Cook Inc., 582 F.3d 1322, 1330 (Fed. Cir. 2009) (noting that different words should typically be given different meanings). The best reading of this language is that an "endoscopic operation environment" includes both the "surgeon's operation station" and the surgical equipment and control heads located away from the "surgeon's operating environment." See '688 Pat. col.19 ll.39-48.

The Court also rejects KSEA's argument based on the claim's teaching that a surgical procedure is performed at the "surgeon's operating station" "with" surgical equipment. See '688 Pat. col.19 ll.40-41. This does not mean that the surgical equipment is necessarily located at the "surgeon's operating station." In context, the claim teaches that the surgical procedure is performed "with" surgical equipment in the sense that the surgical equipment drives the surgical instruments that are located at the "surgeon's operating station" and used on the patient. See id. at col.19 ll.42-48.

S&N's proposed construction comports with the claims' language. Claims 1 and 10 disclose that the surgical procedure is performed at the "surgeon's operating station," "with" surgical equipment. See '688 Pat. col.19 ll.40-41; id. at col.20 ll.48-49, and that the surgical instruments are located at the "surgeon's operating station," id. at col.19 ll.47-48; id. at col.20 ll.55-56. The natural reading of the patent is that the surgeon would be located where the surgical procedure is performed with surgical instruments.

The specification strongly supports the conclusion that the surgeon uses the surgical instruments to perform the surgical procedure within the sterile area.1 See '688 Pat. at 1 (showing the surgeon operating on the patient within the sterile area); id. at 2 (same); id. at col.1 ll.9-13 (describing how the system provides direct control from within the "sterile operating environment"); id. at col.4 ll.40-44 (describing how "sterile control located at the surgeon's operating station allow[s] the surgeon and assistant to make equipment adjustments without breaking sterile procedure").

--- Footnotes ---

1 Although the claims note where objects are not located in the sterile area, at least some of the time, the Court finds that in view of the whole patent this does not exclude objects from being within the sterile field where they are not expressly so designated.

--- End Footnotes ---

- 4440 -
KSEA contends that the "surgeon's operating station" cannot be located in the sterile area because the heads-up display ("HUD") is described as being located at the "surgical operating station," id. at col.4 ll.31-32, and is depicted as outside the sterile area in the diagrams, id. at 1-2. KSEA over-reads the significance of the HUD's placement outside the sterile area in the diagram. The diagram shows that the HUD is "at" the "surgeon's operating station" in the sense that the surgeon may easily observe the HUD from his position within the sterile field. See id. at 1-2; id. at col.4 ll.56-59 (describing how the surgeon may monitor the surgical equipment by viewing the HUD monitor).

KSEA also argues that construing the "surgeon's operating station" as being located within the sterile field ignores the specification's teaching that members of the surgical team, in addition to just the surgeon, may use the control panel located at the "surgeon's operation station." This argument fails because members of the surgical team who are properly scrubbed may clearly use the control panel without breaching the sterile nature of that field.

The Court construes "surgeon's operating station" as the "place within the sterile area of the operating environment where the surgeon and the surgical instruments are located during a surgical procedure."

3782

c. "Stationary"

The term "stationary" in step (1) is not explicitly defined in the specification, and both parties submit several pages debating its meaning. When the patentee does not choose to act as his own lexicographer in the specification, a claim term is to be given its "ordinary and customary meaning." Vitronics, 90 F.3d at 1582.

i. Dictionary Definition of "Stationary"

To determine the ordinary meaning of claim terms, the court may reference dictionaries. Tex. Digital, 308 F.3d at 1202. According to the Random House Dictionary of the English Language 1283 (College ed. 1968), "stationary" means: "1. standing still; not moving. 2. having a fixed position; not movable." Plaintiffs contend both the first and the second definitions apply, asserting that "stationary" means "not movable." Under this interpretation, "stationary" would describe any sort of permanent de/anti-icing fixture at an airport but would distinguish mobile units such as trucks in the Thornton-Trump patent. However, defendants argue only the first definition should apply, contending that "stationary" as "not moving" means fixed or with no moving parts. Under this narrower interpretation, the term "stationary" would only include fixed gantry systems and exclude permanent fixtures with moving parts, such as defendants' product.

When the ordinary meaning of a word comprises "two relevant alternatives," the term "may be construed to encompass both alternatives." Inverness Med. Switz. GmbH v. Warner Lambert Co., 309 F.3d 1373, 1379 (Fed. Cir. 2002); accord Tex. Digital, 308 F.3d at 1203; see also Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001) ("In addition, unless compelled to do otherwise, a court will give a claim term the full range of its ordinary meaning as understood by an artisan of ordinary skill."). Therefore, "stationary" as used in step (1) could comprise a fixed-location permanent installation with moving parts or without moving parts. However, before this interpretation is applied, the court must examine the intrinsic evidence to determine if it "clearly demonstrates" that only one of the definitions was intended. Inverness, 309 F.3d at 1379; see, e.g., Globetrotter Software, Inc. v. Elan Computer Group, Inc., 362 F.3d 1367, 1380 (Fed. Cir. 2004) (looking to intrinsic evidence to decide between two dictionary definitions for the claim term "prevent"); see also Renishaw, 158 F.3d at 1250 ("However, a common meaning, such as one expressed in a relevant dictionary, that flies in the face of the patent disclosure is undeserving of fealty.").

ii. "Stationary" in the Specification

When a term has multiple dictionary definitions, the court must examine the intrinsic evidence to decide which of the possible dictionary definitions apply. Tehrani v. Hamilton Med., Inc., 331 F.3d 1355, 1361 (Fed. Cir. 2003); accord Tex. Digital, 308 F.3d at 1203 (holding that "the intrinsic record must always be consulted to identify which of the different possible dictionary meanings of the claim terms in issue is most consistent with the use of the words by the inventor."); cf. Renishaw, 158 F.3d at 1249 (holding that when "a patent applicant has elected to be a lexicographer by providing an explicit definition in the specification for a claim term . . . the definition selected by the patent applicant controls."). The word
"stationary" appears in only one other place in the specification. In that instance, the term "stationary" is used to reference a boom with articulating arms in contrast to a "truck-mounted boom." '068 patent, col. 17, ll. 29-30. The example from the specification uses the word "stationary" to describe something with moving parts (similar to the articulating boom of defendants' apparatus), thus supporting plaintiffs' definition which allows for moving parts. See, e.g., Ex. 3 to Pls.' Opp'n (Dempsey Dep. at 15) (defendant's description of apparatus having articulating booms). In addition, contrasting the term "stationary" with the term "truck mounted" further supports plaintiffs' interpretation that a stationary apparatus is anything other than a mobile facility such as a de-icing truck. The only explicit reference to the term "stationary" in the specification supports a broad interpretation of the claim term.

11 Column 17, lines 26 through 30 of the '068 patent state:

Examples of such pumps (for the high pressure de-icing (and/or cleaning) operations) are the high-pressure centrifugal type pumps commonly utilized in the chemical industry with stationary and/or truck mounted booms with multiple-section articulating arms.

To support their interpretation of "stationary," defendants point out "more than 100 references" in the specification to the fact that the aircraft travels through the apparatus. 12 Defs.' Reply at 15-16. However, "references to a preferred embodiment, such as those often present in a specification, are not claim limitations." Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1988), cited with approval in Inverness, 309 F.3d at 1379; accord Super Prods. Corp. v. D P Way Corp., 546 F.2d 748, 756 (7th Cir. 1976) ("While the language of the claim must be read in light of the specification and the file wrapper . . . the claim alone is the measure of the invention.") (footnotes omitted); see also 3M Innovative Props. Co. v. Avery Dennison Corp., 350 F.3d 1365, 1367 (Fed. Cir. 2003) (noting that "a patentee need not describe all embodiments of his invention"); Laitram Corp. v. NEC Corp., 163 F.3d 1342, 1347 (Fed. Cir. 1998) ("[A] court may not import limitations from the written description into the claims."); Electro Med. Sys., S.A. v. Cooper Life Scis., Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994) ("Although the specifications may well indicate that certain embodiments are preferred, particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments."). The specification describes one embodiment, a fixed gantry system, capable of performing the process described in claim 25. However, the disclosure of one embodiment does not import the limitations of that embodiment into the claim. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 ("Even when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using 'words or expressions of manifest exclusion or restriction.'") (quoting Teleflex, 299 F.3d at 1327). Because the references in the specification pointed out by the defendants simply describe one particular embodiment, they do not limit claim 25 only to processes performed by fixed gantry systems.

12 Defendants also cite marketing materials that state Whisper Wash is a "drive-thru" apparatus. Defs.' Reply at 15-16. "In considering the claims of a patent, we are constrained to look at the claims in the patent and not the claims of advertising material designed for the purpose of selling a product." Reese v. Elkhart Welding & Boiler Works, Inc., 447 F.2d 517, 523 (7th Cir. 1971). Therefore, because the marketing materials are for advertising purposes, this court cannot consider them in construing the claim.

iii. Prosecution History Regarding "Stationary"

In addition to the claim language and specification, the court may examine the prosecution history, 13 which is "often of critical significance in determining the meaning of the claims." Vitronics, 90 F.3d at 1582. "Where the patentee in the course of his application in the patent office has, by amendment, cancelled or surrendered claims, those which are allowed are to be read in the light of those abandoned and an abandoned claim cannot be revived and restored to the patent by reading it by construction into the claims which are allowed." Schriber-Schroth Co. v. Cleveland Trust Co., 311 U.S. 211, 218, 85 L. Ed.
The file wrapper reveals that the added claim language "providing a stationary apparatus through which the aircraft moves, the apparatus including respective nozzle means" was added in an amendment directly before approval, at the same time as the "one pass" clause. Ex. 3 to Pls.' Mot. for Summ. J. on Non-Unenforceability ('068 File Wrapper at 210). Before the amendment, there was no apparatus requirement; therefore, the claim would have been construed to include processes effected by truck-mounted booms, fixed booms, fixed gantry systems or any effective apparatus. Defendants contend that in making the "stationary" amendment the patentee not only abandoned the truck-mounted means for effecting the process but that patentee also abandoned all fixed-installation articulating-boom means (including defendants' apparatus). However, there is nothing in the prosecution history to suggest that interpretation. In fact, examination of the prior art leads to the opposite conclusion.

"The prior art cited in the file wrapper gives clues as to what the claims do not cover." Autogiro, 384 F.2d at 399. The patent office cited the Thornton-Trump patent both times as the reason for rejecting claim 25 without the "stationary" language. Ex. 3 to Pls.' Mot. for Summ. J. on Non-Unenforceability ('068 File Wrapper at 163, 203). Thornton-Trump provides a preferred embodiment of its process claims as being performed by trucks. See Ex. 3 to Pls.' Mot. for Summ. J. on Non-Unenforceability at (Thornton-Trump patent, col. 2, ll. 61-64) ("It is contemplated that the operation be accomplished with a mobile vehicle. . ."). This suggests that the "stationary" language was added by patentee to avoid the prior art of Thornton-Trump and therefore only the use of trucks or other mobile vehicles for achieving the method was abandoned by the amendment. Compare id. (Thornton-Trump patent, col. 2, ll. 64-68) ("An example of such a [mobile vehicle] unit . . . comprises a truck having articulated booms. . . .") (emphasis added) with '068 patent, col. 7, l. 67 to col. 8, l. 1 ("The present invention defines a central location at an airport for de-icing and anti-icing an aircraft just prior to the flight of the aircraft.") (emphasis added). Because the prosecution history supports the broader interpretation of the claim term "stationary," the interpretation that encompasses both alternate definitions, this court must reject defendants' overly narrow interpretation. Therefore, the court concludes that the claim term "stationary apparatus" describes any fixed-location installation for de/anti-icing an aircraft, containing either articulating booms or a fixed gantry.

"Statue"

Ivoclar asks the Court to construe the claimed term "statue" consistent with the Yukiyo court's construction:

Statue means the positive, substantially entire version of the tooth formed by the investment material when formed within the impression. A synonym for statue is model or die.

Def. 56.1 Ex. 13. PSN believes that the term "statue" should have a modified construction from that provided by the Yukiyo court:

Statue means the positive, substantially entire version of the tooth having at least portions of three sides of the tooth formed by the investment material from the impression.

Def. 56.1 Ex. 14:

When construing a claim, "the context in which a term is used in the asserted claim can be highly instructive." Phillips, 415 F.3d at 1314. In claim 1 of the '530 Patent, the claim describes forming a statue "from said impression" of the tooth. '530
Patent, col. 6, ll. 40-42. It does not extend the definition to forming the statue "within the impression" as in the Yukiyo court's construction. Although the preferred embodiment describes a statue that is "cured and removed from the mold," there is nothing in the patent specification that suggests that the creation of the statue must be limited to that method. "From the impression," as explicitly stated in Claim 1, is sufficient to define the formation of the claimed "statue."

During the course of claims construction briefing, Ivoclar amended its proposed claim construction to remove the phrase "having at least three sides of the tooth" in order to conform to the Yukiyo court's construction that contained no such language. PSN proposes a modified version of Ivoclar's initial proposal by defining a statue as having "at least portions of three sides of the tooth." On the basis of the '530 Patent specification and McLaughlin's statements during the prosecution history, PSN's proposed language better defines "statue" than Ivoclar's revised proposal containing no such language. As Ivoclar itself noted in its reply brief, McLaughlin distinguished the '530 Patent from prior art by noting that his patent taught a "full statue of the tooth" rather than only a single surface and that "the present invention relies upon the use of a tooth statue which inherently involves the use of three sides of the tooth." Def. 56.1 Ex. 10 at 22; Def. Reply Mem. at 6. Because Ivoclar's evidence directly supports the construction proposed by PSN and the specification of the Patent comports with the construction, the Court accepts this portion of PSN's proposed construction.

PSN disputes the use of the terms "model" and "die" as synonyms for "statue" because they may create confusion due to their other uses in the dental veneer field. Pltf. Resp. at 7. While this may be the case for the word "die," which may have other meanings to those skilled in the art and may therefore cause confusion, the synonym "model" is used both in ordinary language as a synonym for statue, and in this case has been used by the inventor himself in the specification as a synonym for the claimed term "statue." See col. 3 ll. 45 ("A model or statue of the tooth or teeth is then produced from the mold."). "The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction." Nystrom v. Trex Co., Inc., 424 F.3d 1136, 1142 (Fed. Cir. 2005) quoting Phillips, 415 F.3d at 1316. Since the term model assists a reader in understanding the use of the term "statue" in the context of dental work, that term is retained from the Yukiyo court's construction.

"Statue" means the positive, substantially entire version of the tooth, having at least portions of three sides of the tooth, formed by the investment material from the impression. A synonym for a statue is a model.

I. Background

Both the plaintiffs and New Holland manufacture and sell in the United States hay harvesting machines known as mechanical drive, center pivot mower conditioners. Plaintiffs began selling their machines in 1992. New Holland entered the market in the fall of 1996. The plaintiffs' machine is manufactured and sold pursuant to the '859 patent.

Of primary importance in this case is a new feature the '859 patent added to the prior art of hay harvesting machines. This new feature was a "steering structure" interposed between the directional pulling mechanism (called the "tongue") and the cutting-power transfer mechanism (called the "gearbox") to transmit the swinging motion of the tongue to the gearbox. The parties only dispute in this Markman proceeding is the meaning and scope of this "steering structure" as disclosed in claims 1 and 10 of the '859 patent.

Claim 1 of the '859 patent is as follows:

[We claim,] in a pull-type crop harvesting machine, the improvement comprising:

a mobile frame;

a pull-tongue pivotally coupled with the frame for horizontal adjusting movement about a first upright axis between a number of angular positions relative to the path of travel of the machine for varying the lateral position of the machine relative to a towing vehicle;

a harvesting header supported by the frame in a position for performing harvesting operations on a crop as the machine
is towed across a field,

said header having driveable operating components associated therewith;

a mechanical drive line extending along and rotatably supported by the tongue for supplying driving power to said operating components in said angular positions of the tongue;

a junction box on the header having an input shaft and an output shaft rotatably supported by the box and operably intercoupled in fixed angular relation to one another within the box,

said input shaft being operably connected with said drive line for receiving driving power therefrom and said output shaft being operably connected to said operating components for driving the same,

said box being pivotally mounted on the header for swinging movement about a second upright axis spaced horizontally from the first axis; and

steering structure connected between the junction box and the tongue for causing the junction box to swing responsively when the latter is pivoted about said first axis between its various angular positions.

(emphasis added). Claim 10 of the '859 patent is as follows:

In a pull type harvesting machine as claimed in [claims 1-9],

said steering structure including telescoping linkage having a front pivotal connection with the tongue at a point which is at least approximately equidistant from said opposite ends of the telescopic section.

The defendants contend that the proper construction of the "steering structure connected between the junction box and the tongue" clause of claim 1 is as follows:

a direct fastening of a steering structure to the tongue at one end and the pivoting gearbox housing or extension thereof at the other end, such as by bolting, which permits some relative movement, such as a telescoping action, to occur between those two connection points as the tongue is swung laterally.

The plaintiffs disagree. The plaintiffs believe that the proper construction of the steering structure clause is as follows:

a mechanical steering structure separate from the drive line that begins at the tongue and ends at the gearbox and that transmits the swinging motion of the tongue to the gearbox during swinging of the tongue.

II. Discussion

When construing claims in a patent, the court must focus on how the claim would be interpreted by one of ordinary skill in the art at the time the patent was issued. Markman, 52 F.3d at 986. The court must look first to the claims, the specification, and the prosecution history of the patent. Markman, 52 F.3d at 979. Referring to claims in a patent may assist the court in determining the intended meaning of a disputed claim, but the court may not read limitations from other claims into an independent claim. See Environmental Designs, Ltd. v. Union Oil, Inc., 713 F.2d 693, 699 (Fed. Cir. 1983); Kustom Signals, Inc. v. Applied Concepts, Inc., 995 F. Supp. 1229, 1234, 1998 U.S. Dist. LEXIS 2695, at *12, 1998 WL 94903, at *4 (D. Kan. 1998). Claims must be interpreted in light of the patent specification, of which they are a part. Markman, 52 F.3d at 979. The specification contains a written description of the invention and includes a best mode or preferred embodiment of the invention. See Environmental Designs, Ltd. v. Union Oil, Inc., 713 F.2d 693, 699 (Fed. Cir. 1983); Kustom Signals, Inc. v. Applied Concepts, Inc., 995 F. Supp. 1229, 1234, 1998 U.S. Dist. LEXIS 2695, at *12, 1998 WL 94903, at *4 (D. Kan. 1998). Claims must be interpreted in light of the patent specification, of which they are a part. Markman, 52 F.3d at 979. The specification contains a written description of the invention and includes a best mode or preferred embodiment of the invention. Kustom Signals, Inc., 995 F. Supp. at 1231, 1998 U.S. Dist. LEXIS 2695, at *3, 1998 WL 94903, at *5 (citing Markman, 52 F.3d at 979). Not everything expressed in the specification must be read into the claims, however. Intervet Am., Inc. v. Kee-Vet Labs., Inc., 887 F.2d 1050, 1053 (Fed. Cir. 1989) ("Limitations appearing in the specification will not [normally] be read into claims . . . interpreting what is meant by a word in a claim is not to be confused with adding an extraneous limitation appearing in the specification, which is improper.") (citation and internal quotation marks omitted). Thus, the specification normally identifies only the best mode of practicing an invention, not the scope of the invention. See Transmatic, Inc. v. Gulton Indus., Inc., 53 F.3d 1270, 1276 (Fed. Cir. 1995); Kustom Signals, Inc., 995 F. Supp. at 1231,
1998 WL 94903, at *5. The court should also consider, within its proper context, the patent's prosecution history. Markman, 52 F.3d at 980 ("Although the prosecution history can and should be used to understand the language used in the claims, it too cannot enlarge, diminish, or vary the limitations in the claims.") (citations and internal quotation marks omitted).

If necessary, the court may also, in its discretion, consider extrinsic evidence such as expert and inventor testimony, dictionaries, and learned treatises. Markman, 52 F.3d at 980. Extrinsic evidence, however, "is to be used for the court's understanding of the patent, not for the purpose of varying or contradicting the terms of the claims." Id. at 981. Once the court arrives at an understanding of the claim language, the court must pronounce the meaning of that language as a matter of law. Id.

A. Claim 1

Congress has allowed patentees the ability to express their claims in functional, rather than structural, language, but the exercise of that ability comes at a price. "An element in a claim for a combination may be expressed as a means or step for performing a specified function, without the recital of structure, material or acts in support thereof; and such claim shall be construed to cover the corresponding structure, materials, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112 P 6 (1994) (emphasis added) (sometimes referred to as the "means-plus-function" formulation). Defendant contends that claim 1 of the '859 patent falls within the reach of section 112(6). Plaintiffs contend claim 1 does not fall within the statute's reach. If defendant is correct, the court must "limit the breadth of [the] claim language by restricting its scope to the structure disclosed in the specification and equivalents thereof." Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1582 (Fed. Cir. 1996).

Ordinarily, the question whether a claim element triggers section 112(6) is not difficult. Id. "Claim drafters conventionally use the preface 'means for' (or 'step for') when they intend to invoke section 112(6), and there is therefore seldom any confusion about whether section 112(6) applies to a particular element." Id. It would be improper to conclude, however, that section 112(6) is triggered only if the claim uses the word "means." Id. at 1584; Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996), cert. denied, 139 L. Ed. 2d 20, 118 S. Ct. 56 (1997). Nonetheless,

the use of the term 'means' has come to be so closely associated with 'means-plus-function' claiming that it is fair to say that the use of the term 'means' (particularly as used in the phrase 'means for') generally invokes section 112(6) and that the use of a different formulation generally does not.

Greenberg, 91 F.3d at 1584.

Under section 112(6), patentees are "afforded the option" of using the means-plus-function format. Id. The question in discerning whether section 112(6) applies, then, is "whether, in the selection of claim language, the patentee must be taken to have exercised that option." Id. The court must decide this question on an element-by-element basis, based upon the patent and the prosecution history. Cole, 102 F.3d at 531. A claim falls outside the ambit of section 112(6) if it recites a "definite structure which performs the described function." Id. Thus, the mere fact that a particular mechanism or structure is defined in functional terms "is not sufficient to convert a claim element containing that term into a 'means for performing a specified function' within the meaning of section 112(6)." Greenberg, 91 F.3d at 1583.

The court, after careful consideration, has determined that the steering structure clause of claim 1 does not fall within the meaning of section 112(6). The clause "steering structure connected between the junction box and the tongue for causing the junction box to swing responsively when the latter is pivoted about said first axis . . ." clearly has some structural language and some functional language. Nonetheless, like the claim element at issue in Greenberg,

the element in question did not use conventional "means-plus-function" language, no other element of the claim was in means-plus-function form, and nothing cited to [the court] from the prosecution history or elsewhere suggests that the patentee intended to claim in that fashion. There is therefore no reason to read the claim language in this case as reciting a means for performing a function, within the meaning of section 112(6).

Id. at 1584.
The steering structure clause at issue here discloses structure sufficient to avoid the means-plus-function limitation. "Steering structure," as used in claim 1, is used in the same manner as the other structural components of claim 1. Thus, the claim would give one skilled in the art no reason to believe that a "steering structure" is any less a "definite structure," see Cole, 102 F.3d at 531, than a "mobile frame," "pull tongue," "harvesting header," "mechanical drive line," "junction box," "input shaft," or "output shaft." Moreover, the language following "steering structure," when read in conjunction with the rest of the claim 1 language, provides further detail sufficient to enable one skilled in the art to understand the meaning of the term. The steering structure disclosed in claim 1 is not just an abstract means for performing a specified function, it is a specific device "connected between the junction box and the tongue." See Cole, 102 F.3d at 531 ("The claim describes not only the structure . . . but also its location . . . . An element with such a detailed recitation of its structure, as opposed to its function, cannot meet the requirements of the statute."). The plaintiffs have provided the court with an extensive list of patents using the term "steering structure" as a noun (not a means for accomplishing a function) in the mechanical arts. This list further convinces the court that an artisan of ordinary skill would understand the disputed term to have structure sufficient to avoid application of section 112(6). See Greenberg, 91 F.3d at 1583 ("What is important is not simply that [the element at issue] is defined in terms of what it does, but that the term, as the name for a structure, has a reasonably well understood meaning in the art.")

2 Defendant filed a motion in limine seeking to exclude these patents as hearsay, as not properly authenticated, as improper extrinsic evidence, and as untimely presented. The court reserved ruling on this motion but now rejects these arguments and denies defendant's motion. The court rejects defendant's hearsay argument because the documents offered are not hearsay. See Fed. R. Evid. 801(c) (hearsay is a statement offered to prove the truth of the matter asserted). Plaintiff offers these documents not to prove the truth of any of the matters which they assert, but rather to prove that various patents use the term steering structure as a noun in a variety of contexts. In any event, even if the patents were hearsay, they would be subject to the public records exception to the hearsay rule. See Fed. R. Evid. 803(8)(B) (providing hearsay exception for records of public agencies setting forth matters observed pursuant to duty imposed by law as to which there is a duty to report).

The court rejects defendant's authentication argument because the court has opted to take judicial notice of the contents of the proffered patents. See Fed. R. Evid. 201(b)(2), (c) (court has discretion to take judicial notice of facts that are capable of accurate and ready determination by resort to sources whose accuracy cannot reasonably be questioned); Thomas & Betts Corp v. Panduit Corp., 65 F.3d 654, 664 n.12 (7th Cir. 1995) (taking judicial notice of patent in a trade dress infringement case); Vitek Sys., Inc. v. Abbott Labs., 675 F.2d 190, 192 n.4 (8th Cir. 1982) (court may take judicial notice of Patent & Trademark Office Documents); Coinstar, Inc. v. Coinbank Automated Sys, Inc., 998 F. Supp. 1109, 1998 WL 111648, at *3 (N.D. Cal. 1998) (taking judicial notice of patent in a patent infringement case). The contents of a patent are capable of accurate and ready determination by resort to widely used legal online research services.

The court rejects defendant's relevancy argument because it is within the court's discretion to hear extrinsic evidence "to understand the language used in the claims." Markman, 52 F.3d at 980 (citations omitted).

The court rejects defendant's timeliness argument because the defendant was not prejudiced by the plaintiffs' ability to present evidence of other patents. There is no evidence that plaintiff deliberately withheld the contents of these patents until such time as the defendants were unable to reply. Plaintiff presented the patents in direct response to defendant's argument that the term steering structure was merely a recitation of an indefinite steering means by which various functions are performed. Defendant had every opportunity to request an opportunity to reply to plaintiff's response. Defendant did not do so. Moreover, the existence of these patents could not have been a surprise to the defendant. Anyone, including the court, has access to these patents through widely used legal online research services. To the extent defendant's motion in limine seeks to exclude other evidence proffered by plaintiff, the motion is also denied. The court has not considered this evidence. Accordingly, there is no need to exclude it.

Defendant argues that the prosecution history reveals that the Patent and Trademark Office ("PTO") must have interpreted the steering structure clause in claim 1 as a means-plus-function clause. This argument is without merit because the PTO did not begin interpreting claims under section 112(6) until February 14, 1994. See In re Donaldson, 16 F.3d 1189, 1193-94
The court believes that a person of ordinary skill in the art of agricultural engineering would understand the "steering structure" clause in claim 1 to have a plain meaning in light of the claims in the '859 patent, the '859 specification, and the '859 prosecution history. The court believes the clause "steering structure connected between the junction box and the tongue for causing the junction box to swing responsively when the latter is pivoted about said first axis between its various angular positions" means "a steering structure separate from the drive line that operatively interacts with the tongue at one end and operatively interacts with the junction box at the other end and that transmits the swinging motion of the tongue to the junction box during swinging of the tongue." The steering structure must be "separate from the drive line" because it is mentioned separately from the drive line clause in claim 1, thus signifying that a person of ordinary skill in the art would consider the drive line and the steering structure to be two separate items. The steering structure must "operatively interact with the tongue at one end and operatively interact with the junction box at the other end" because the claim reveals that the steering structure must be "connected between the junction box and the tongue." The steering structure must "transmit the swinging motion of the tongue to the junction box during swinging of the tongue" because the claim reveals that the steering structure must "cause[] the junction box to swing responsively... when the [tongue] is pivoted."

a. Construction in Light of Claims

Defendant advocates a construction different from the court's. 3 Defendant argues that the clause "connected between the junction box and the tongue" contemplates a fixed attachment of the steering structure at each terminus, such as by a bolt or a pivot pin. Defendant argues first that the term "connected" connotes a junction that is "joined or fastened together." See American Heritage Dictionary of the English Language, (3d ed. 1992); see also Webster's Third International Dictionary, 480 (1986) ("joined or linked together"); Kustom Signals, Inc., 995 F. Supp. 1229, 1998 U.S. Dist. LEXIS 2695, at *1, 1998 WL 94903, at * (term should be given its ordinary and accustomed meaning when there is no indication in the specification that the inventor intended otherwise) (citing Hoechst Celanese Corp. v. BP Chems, Ltd., 78 F.3d 1575, 1578 (Fed. Cir. 1996)). Two objects joined or fastened together, argues the defendant, cannot move freely relative to one another. Thus, the connected between clause in claim 1 must contemplate a fixed attachment not allowing for any relative movement.

3 The court's construction of claim 1 is nearly identical to the plaintiffs' proposed construction.

The court rejects defendant's argument because the language of the claim is not as narrow as defendant advocates. The court agrees with the defendant that two objects that are connected, under the ordinary meaning of that term, cannot move entirely freely relative to one another. The court is not convinced, however, that an artisan of ordinary skill would understand the term connected to require a rigid attachment that does not allow for relative motion. The claim itself clearly contemplates some pivotal movement between the tongue and the steering structure. 4 The definition of connected as "joined or fastened together," then, surely cannot preclude all relative movement. Moreover, the modification of the term connected by the term "between" supports the court's interpretation. For example, an object that is "connected between" two other objects is likely to be joined to the other objects in a manner less rigid than an object that is "connected to" the other objects. See Webster's Third International Dictionary, 209 (1986) (between defined as, inter alia, "filling the space limited by two objects"). This interpretation is further supported by other claims in the '859 patent. Dependent claim 11 of the '859 patent sets forth specific details concerning the connections at each end of the steering structure. The claim describes "a front connection of the [steering structure telescoping] linkage including a universal pivot." The difference in specificity between the description of the steering structure in claims 1 and 11 supports a broad reading of claim 1 and a narrow reading of claim 11. See Transmatic, Inc. v. Gulton Indus., 53 F.3d 1270, 1277-78 (Fed. Cir. 1995) (district court erred when it read claim limitations from narrow claims onto broader claims). The Federal Circuit has acknowledged that, in a proper case, the term "connected to" can be construed broadly enough to encompass two distant elements which are connected by intervening elements. See Ethicon Endo-Surgery, Inc. v. United States Surgical Corp., 93 F.3d 1572, 1578 (Fed. Cir. 1996). This court's
interpretation of the '859 patent does not stretch the concept of connection nearly so far. The court believes that the term connected, properly construed in claim 1 of the '859 patent, means that the tongue and the steering structure "operatively interact," see id. (noting that the term "connection" had no meaning, in the context of the patent there at issue, unless the two connected objects "operatively interacted with one another), with one another allowing for some relative movement but not allowing for complete freedom of movement.

4 Defendant does not argue that the claim should be construed to allow no pivotal movement between the tongue and the steering structure.

b. Construction in Light of Specification

Defendant next contends that the specification of the '859 patent, which discloses a steering structure linked to the tongue by a bolted, pivotal connection, compels the court to construe the steering structure clause in claim 1 to require such a connection. The court disagrees. Although claims must be read in light of the patent specification, see Markman, 52 F.3d at 979, limitations appearing in the specification may not be read into claims. Intervet Am., Inc., 887 F.2d at 1053. Unless the means plus function limitation of section 112 paragraph 6 applies, the specification identifies only the best mode of practicing an invention, not the scope of the invention. See 35 U.S.C. § 112 P 6; Greenberg, 91 F.3d at 1582; Transmatic, 53 F.3d at 1276. It is the claims which measure the scope of the invention. See SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1121 (Fed. Cir. 1985).

The court rejects defendant's argument because it seeks a construction that would improperly read limitations in the specification onto claim 1. Even though the preferred embodiment of the '859 patent is a machine in which the steering structure is connected to the tongue by a bolted, pivotal connection, the language of claim 1 is broader than this embodiment. No usage of the terms connected or connected between in the specification suggests otherwise, other than in the context of explaining the preferred embodiment. See E.I. Du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988) (using specification to interpret what the patentee meant by a word or phrase in a claim is "not to be confused with adding an extraneous limitation appearing in the specification, which is improper. By 'extraneous,' we mean a limitation read into a claim from the specification wholly apart from any need to interpret what the patentee meant by particular words or phrases in the claim. 'Where a specification does not require a limitation, that limitation should not be read from the specification into the claims."') (citations omitted).

Far from supporting defendant's proposed interpretation of the steering structure clause, the court believes the '859 patent specification supports the court's interpretation. The second sentence of the '859 patent abstract describes a telescoping steering linkage "between the swing tongue and the gearbox" without reference to any particular connection. This reference serves further to convince the court that the steering structure clause of claim 1 does not require a bolted, pivotal connection, as urged by the defendants.

c. Construction in Light of Prosecution History

Defendant contends that the prosecution history of the '859 patent supports a construction of the steering structure clause to require a bolted, pivotal connection. Defendant points to U.S. Patent No. 4,858,418 ("'418 patent"), which was part of the '859 patent's prosecution history. Defendant argues that the '418 patent anticipated claim 1 of the '859 patent if the '859 patent's steering structure clause is not construed to require a bolted, pivotal connection between the steering structure and the tongue. If defendant is correct that the '418 patent anticipated claim 1 as the court has construed it, then the court's construction would be incorrect because the patent examiner could not have approved the '859 patent under such construction. See Lockwood v. American Airlines, Inc., 107 F.3d 1565, 1573 (Fed. Cir. 1997) ("Claims may not be construed one way in order to obtain their allowance and in a different way against accused infringers.").

The court rejects defendant's argument concerning the '418 patent because it is convinced that the '418 patent did not anticipate claim 1. The '418 patent discloses a hay harvesting machine in which the drive line and the steering mechanism are one and the same. This concept does not anticipate claim 1 of the '859 patent because claim 1 discloses a steering
structure separate from the drive line.

d. Construction in Light of Expert Testimony

Finally, defendant relies on expert testimony to support its proposed construction. Defendant argues that the testimony of its expert, Mr. Willis R. Campbell, supports a finding that a person of ordinary skill in the art would understand the claim language to require a fixed, bolted connection. Defendant also argues that the Niemeyer RO 301-GK machine, which defendant alleges is prior art to the '859 patent, anticipates claim 1 of the '859 patent. The court rejects these arguments.

In construing claims, the court must look to the language of the claims, the specification, and the prosecution history. Markman, 52 F.3d at 979. Extrinsic evidence, while appropriate for use in the court's understanding of the terms of a patent, may not be used for the purpose of varying or contradicting the terms of the claims. Id. at 981; Bell & Howell Document Management Prods. Co. v. Altek Sys., 132 F.3d 701, 705-06 (Fed. Cir. 1997) ("When the intrinsic evidence is unambiguous, it is improper for the court to rely on extrinsic evidence such as expert testimony for purposes of claim construction."). If the court wishes to refer to extrinsic evidence as a help in understanding technology and terminology, documentary evidence, particularly prior art, technical treatises, and dictionaries, is preferred over expert testimony. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1584 n.6 (Fed. Cir. 1996).

The court rejects Mr. Campbell's testimony concerning how an artisan of ordinary skill would construe claim 1 of the '859 patent because it does not believe there is any genuine ambiguity in the text of claim 1. See Vitronics Corp., 90 F.3d at 1584 ("Only if there were still some genuine ambiguity in the claims, after construction of all available intrinsic evidence, should the trial court . . . resort to . . . expert testimony."). Mr. Campbell's testimony, although it generally was helpful to the court's concrete understanding of the workings of the plaintiffs' machine and the disputes surrounding claim 1 of the patent, is simply inconsistent with the court's reading of the words of claim 1, the patent specification, and the little prosecution history with which the court has been provided. See Bell & Howell Document Management Prods. Co., 132 F.3d at 706 ("Patents should be interpreted on the basis of their intrinsic record, not on the testimony of such after-the-fact 'experts' that played no part in the creation and prosecution of the patent . . . . Any expert testimony that is inconsistent with unambiguous intrinsic evidence should be accorded no weight."). Accordingly, the court gives no weight to Mr. Campbell's testimony concerning how an ordinary artisan would construe claim 1.

Similarly, the court rejects Mr. Campbell's testimony concerning the Niemeyer machine. Evidence related to the Niemeyer machine, which was not part of the patent's prosecution history, is exactly the kind of extrinsic evidence the Federal Circuit has prohibited the court from considering because the defendant's evidence (consisting primarily of expert testimony) and arguments related to the machine are "for the purpose of varying . . . the terms of the claims." Id. Defendant has offered this evidence not in an attempt to assist the court in understanding how an artisan of ordinary skill would interpret the disputed claims, see Markman, 52 F.3d at 981 (citing Advanced Cardiovascular Sys., Inc. v. Scimed Life Sys., Inc., 887 F.2d 1070, 1076 (Fed. Cir. 1989) (Newman, J., dissenting)), but rather in an attempt to convince the court that the words of claim 1 mean something other than their plain language would dictate. In any event, there are factual disputes concerning whether the Niemeyer machine is prior art or anticipatory at all. Cf. In re Schreiber, 128 F.3d 1473, 1477 (Fed. Cir. 1998) ("The question whether a claim limitation is inherent in a prior art reference is a factual issue."). Accordingly, the court exercises its discretion to reject the evidence and arguments concerning the Niemeyer machine. See Markman, 52 F.3d at 981 (citing Seattle Box Co. v. Industrial Crating & Packaging, Inc., 731 F.2d 818, 826 (Fed. Cir. 1984) ("A trial judge has sole discretion to decide whether or not [it] needs, or even just desires, an expert's assistance to understand a patent. We will not disturb that discretionary decision except in the clearest case.").

5 Defendant's arguments that the Niemeyer machine is anticipatory rest largely on ex parte measurements taken by Mr. Campbell. Mr. Campbell's testimony in this regard is subject to "the established doctrine that evidence of experiments conducted by an interested party, in the absence of his adversary, is always received with suspicion and given only negligible probative value." In re Newman, 782 F.2d 971, 974 (Fed. Cir. 1986) (citation omitted).

6 Plaintiff moved to strike the testimony of Mr. Campbell and certain other evidence related to the Niemeyer machine. The court denies this motion but, as set forth above, has not credited the evidence.
Claim construction is a question of law that we review de novo. Vitronics Corp v. Conception, Inc., 90 F.3d 1576, 1578 (Fed. Cir. 1996). We construe claim language in accordance with its ordinary meaning, as defined by a person having ordinary skill in the art. See Phillips v. AWH Corp., 415 F.3d 1303, 1311-19 (Fed. Cir. 2005) (en banc). This inquiry is informed by the context of the entire patent, including the specification and the other claims, and, where relevant, the prosecution history. Id. The trial court construed "stent" as "a device implanted to maintain the patency of a vessel." Claim Construction Order, slip op. at 2. Medtronic argues that it erred by improperly incorporating a functional limitation into the construction, i.e., maintaining patency of a vessel. We disagree. The invention is described as an "endovascular support device." E.g., '331 patent, col. 3, l. 21 (emphasis added). In addition, the specification explicitly states that stents are devices "for mechanically keeping the affected vessel open." Id. at col. 2, ll. 17-18. Because the trial court's claim construction is consistent with the specification and the ordinary meaning of the term "stent," we find it to be correct.

1. "Stent." Consistent with the ordinary meaning, 1 the independent asserted claims, 2 the written description 3 and the background of the art, 4 the court construes "stent" to mean "a device implanted to maintain the patency of a vessel." 5

2 Claim 1, '331 patent, col. 7, l. 1; claim 1, '278 patent, col. 6, ll. 55-56; claim 1, '053 patent, col. 6, l. 41; claim 8, '053 patent, col. 7, l. 9; claim 16, '053 patent, col. 7, l. 46; claim 24, '053 patent, col. 8, l. 14; claim 27, '053 patent, col. 8, l. 37.

3 '331 patent, col. 4, ll. 29-30; '278 patent, col. 4, ll. 24-25; '053 patent, col. 4, ll. 22-23.

4 '331 patent, col. 2, ll. 16-22; '278 patent, col. 2, ll. 16-22; '053 patent, col. 2, ll. 18-24.

5 Defendants argue that "stent" should be limited to a stand alone device, but the intrinsic evidence does not support such a construction. The written description clearly indicates that "multiple stents may be used in the treatment of a single lesion." ('331 patent, col. 6, ll. 26-31) Medtronic did not disclaim multiple stents during the prosecution of the '331 patent because its arguments were directed at connections between parts of the stent and not at the use of multiple stents to treat a single lesion. (D.I. 240 at 101, 151, 226) Nevertheless, even when used in multiples, each stent must be a functional stent.
6. "Stent"

The term "stent" is used in both the '141 Patent and each of the Wiktor Patents. Medtronic argues for a construction of this term that would be applied uniformly to each of the patents. Gore contends that the term "stent" in the Jervis '141 Patent should be construed differently from the term "stent" in the Wiktor Patents. The Court concurs with Gore that the terms have different meanings in the '141 Patent and the Wiktor Patents. The Court, however, is not persuaded by many of the limitations Gore seeks to include in the construction of the term.

a. The '141 Patent.

Gore argues that the term "stent" in the '141 Patent means "a wire, typically in the shape of a tubular coil, used to keep a body vessel open." To the extent Gore is seeking a construction that includes a reference to the material from which the stent is made, the claims expressly note that the stent is composed of a memory alloy or a shape memory alloy. (See '141 Patent, 11:22-23 ("The device of claim 1 wherein the memory alloy element is a stent."); id., col. 11:32-36 ("… the stent comprising a shape memory alloy …").) Furthermore, independent claim 18 specifically claims a "wire stent," and dependent claim 22 specifically claims "[t]he device of claim 1, 11, 15 or 18 wherein the stent is a coil stent. (Id., 13:22, 14:22-23 (emphasis added).)

As previously noted, the doctrine of claim differentiation recognizes "that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope." Andersen Corp., 474 F.3d at 1369 (quoting Karlin Tech. Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999)); see also Acumed LLC v. Stryker Corp., 483 F.3d 800, 806 (Fed. Cir. 2007) (quoting Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004)) ("[T]he presence of a dependent claim that adds a particular limitation raises a presumption that the limitation in question is not found in the independent claim.") The presumption of claim differentiation "is especially strong when the limitation in dispute is the only meaningful difference between an independent and dependent claim, and one party is urging that the limitation in the dependent claim should be read into the independent claim." SunRace Roots Enter. Co. v. SRAM Corp., 336 F.3d 1298, 1303 (Fed. Cir. 2003). The Court has considered Gore's arguments but finds that the specification and prosecution history submitted do not overcome the presumption that the dependent claims differ in scope from the independent claims.

Accordingly, the Court construes the term "stent," as used in the '141 Patent, to mean: "a supporting device."

b. The Wiktor Patents.

With respect to the Wiktor Patents, Gore argues that the term "stent," should be construed to mean "a bare low memory metal wire stent without any attached fabric or graft material that would be obstructive to any supportive vessels." Gore relies on language in the specification that refers to "[t]he stent of this invention is characterized by the low memory level of the relatively easily deformable metal used for the wire." ('062 Patent, 2:51-54.)

Medtronic again relies on the principles of claim differentiation in support of its proposed construction. For example, Medtronic notes that dependent claim 2 of the '828 Patent claims "[t]he intravascular stent of claim 1, wherein said helically coiled wire is a low memory metal." (Bianrosa Decl., Ex. 7 (828 Patent, 7:53-54); see also id., 8:57-59.) The "low memory metal" limitation is the only meaningful difference between that claim and independent claim 1 of the '828 Patent. It also is the only meaningful difference between independent claim 14 and dependent claim 17 of the '062 Patent. Thus, the presumption of claim differentiation is especially strong. SunRace Roots, 336 F.3d at 1303.

Gore also relies on cases such as Honeywell Int'l Inc. v. ITT Indus., Inc., 452 F.3d 1312 (Fed. Cir. 2006), Inpro II Licensing
Accordingly, the Court construes the term "stent," as used in the Wiktor Patents to mean: "a supporting device, without any attached fabric or graft material."
ORDER ON MOTION TO RECONSIDER CLAIM CONSTRUCTION OF "STENT"

INTRODUCTION

This matter comes before the Court upon consideration of the motion for reconsideration filed by Plaintiffs, Medtronic, Inc., Medtronic, U.S.A., Inc., and Medtronic Vascular, Inc. (collectively "Medtronic"). The matter is fully briefed, and the Court finds the matter suitable for disposition without oral argument. The Court HEREBY GRANTS Medtronic's motion for reconsideration.

Also before the Court is Medtronic's request for leave to file the Expert Declaration of Dr. Dimitris Lagoudas in support of its motion for reconsideration, which responds further to the Cragg article that fueled, in part, Medtronic's request for reconsideration. The Court has not considered the Cragg article to which the declaration responds in reconsidering the construction of the term "stent." Accordingly, the Court DENIES AS MOOT this latter motion.

DISCUSSION

1

Footnotes

1 The Court shall not repeat the standards applicable to claim construction, which are set forth in full in its Order construing the claims, and which have been applied in this Order. (See Claim Construction Order at 4:4-7:5.)

On October 19, 2007, this Court issued its Claim Construction Order. In that Order, the Court construed the term "stent," as it is used in U.S. Patent Nos. 4,886,062 ("the '062 Patent"), 6,656,219 ("the '219 Patent"), and 6,923,828 ("the '828 Patent") (collectively, "the Wiktor Patents") to mean: a supporting device, without any attached fabric or graft material. (Docket No. 91.)

On October 29, 2007, Medtronic filed a motion for clarification of the Court's construction of this term to determine if the Court had intended an "open-ended" or a "closed-ended" construction. (Docket No. 93.) On October 30, 2007, the Court clarified that, in Medtronic's terms, it intended a "closed-ended" construction, and granted Medtronic leave to file the instant motion addressing whether the Court's construction was correct or whether the term stent should be construed to mean "a supporting device."

Having considered the parties' arguments, relevant legal authority, and the record in this case, the Court concludes that its prior construction was incorrect and GRANTS Medtronic's motion. When the term stent is used in the preamble of the claims, it is followed by the open-ended transitional term "comprising." This term supports Medtronic's position that the claims may incorporate additional, unrecited elements. See, e.g., CollegeNet, Inc. v. Apply Yourself, Inc., 418 F.3d 1225, 1235 (Fed. Cir. 2005); Vehicular Techs. Corp. v. Titan Wheel Int'l, Inc., 212 F.3d 1377, 1383-84 (Fed. Cir. 2004) ("A drafter uses the term 'comprising' to mean 'I claim at least what follows and potentially more."). Moreover, upon further review of the claims and the specification, the Court cannot say Wiktor clearly disavowed or disclaimed the broad construction of "stent" that Medtronic seeks. Accordingly, the Court cannot say that the term "stent" should be limited to a bare stent, reconsideres and reverses its previous construction, and concludes that the term "stent" as used in the Wiktor Patents should be construed to mean "a supporting device."

GO BACK

(1) "Stent." A device, made of a body-compatible material, used to widen a blood vessel or other body opening (also called a "lumen"), and to maintain the resultant size of the blood vessel or lumen.
d. "stent-deployment catheter"

The term "stent-deployment catheter" appears in claims 1, 2, and 4. ev3 proposes that this term be construed as "a catheter for supporting and delivering a stent. The catheter may or may not include a balloon and the catheter may or may not include a stent." Boston Scientific has not proposed an alternative construction. There is no intrinsic evidence supporting the second part of ev3's proposed construction. The Court therefore construes "stent-deployment catheter" as "a catheter for supporting and delivering a stent." 3

3 This construction also applies to the term "stent-deployment catheter" in the '987 Patent.

3. "Stent member." Consistent with claim 1 of the '382 patent and the written description, the court construes "stent member" to mean "a stent."

10 '382 patent, col. 6, ll. 44-57.
11 See supra note 9.
(Fed. Cir. 1999). Essentially the dispute revolves around whether the claimed "step section" can be limited to the particular three-dimensional depiction shown as a preferred embodiment. CTS, of course, says it is not and that the common and ordinary meaning of step includes a planar, i.e., two-dimensional configuration, as well as three-dimensional configuration, because the stated purpose of the step section, namely force concentration, can be achieved by either configuration. Indeed, evidence that a "step section" can be a planar or a three-dimensional offset according to the ordinary meaning of the word "step" as used by those skilled in the mechanical arts is amply demonstrated in dictionaries. A "step" is merely an offset portion. See e.g., Knight's American Mechanical Dictionary (1876), page 2375. See also Oxford English Dictionary, 3d ed. (2004).

TK's proposed interpretation, "a portion of the substrate that extends downwardly from the center section to an outer section of the substrate" is too narrow. The "extends downwardly" language is imported from the preferred embodiment of the specification. See '013 pat., col. 3, II. 11-12. As noted above, it is improper to read a limitation from the specification into the claims. Even when the specification describes a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using words or expressions of manifest exclusion or restriction. TK has not identified any such words or expressions of manifest exclusion or restriction. There is none.

In the section "Detailed Description of the Preferred Embodiments" the step sections are described as "extend[ing] downwardly generally perpendicularly on both sides of center section," Id. at col. 3, II. 11-12. However, this restriction does not appear in the Summary of the Invention, nor does it appear in the paradigm claim. Rather, it only appears in the preferred embodiment. Both the Summary of the Invention and the claims more broadly characterize the "step section" as the portion of the substrate that concentrates the weight (force) onto the center section. Id. at col. 2, II. 22-24 and col. 3, II. 17-18. There is no indication, clear or otherwise, that the patentee intended to exclude a two-dimensional step section or limit the invention to a three-dimensional step. Absent a clear disavowal or contrary definition in the specification or the prosecution history, the patentee is entitled to the full scope of the claim language. Home Diagnostics, Inc. v. LifeScan, Inc., 381 F.3d 1352, 1358 (Fed. Cir. 2004).

CTS' interpretation is also supported by the intrinsic evidence. Figure 1 shows that the step section (16) is located between the center section (14) and the outer section (18). The specification further teaches that the purpose of the "step section" is to concentrate a force onto the center section. Id. at col. 2, II. 22-24. Claim 1 states as such. This force concentration can occur if the "step section" is either a planar or three-dimensional offset. Thus, contrary to TK's position, the specification does not require that the "step section" extends downwardly from the center section. Id. at col. 2, II. 17-32; and col. 3, II. 10-19. Instead, such a configuration is merely a preferred embodiment.

Finally, CTS' interpretation of the term "step section" is further supported by the doctrine of claim differentiation. Claim differentiation stands for the "presumption that each claim in a patent has a different scope." See Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380 (Fed. Cir. 2006). Independent claim 8 of the '013 patent characterizes the weight sensor substrate as being "gull wing shaped." Id. at col. 5, II. 5-9. This gull wing shape is found as a preferred embodiment, and is directed to a three-dimensional type of step section. As such, claim 1 of the '013 Patent (as well as claim 5 of the '361 Patent) is presumed to be of different scope from claim 8 of the '013 Patent (and Claim 11 in the '361 Patent), and cannot be limited to the three-dimensional step embodiment. The term "step section" means what it says. TK has not overcome this heavy presumption.

Accordingly, the Court adopts CTS' interpretation of "step section" to mean "the offset portion of the substrate between the center section and the outer section and the outer section of the substrate."

6. Stepper Motor

The ordinary meaning of "stepper motor" is a motor that rotates in short and essentially uniform angular movements rather than continuously. Neither the patent specification nor the prosecution history reveals a different definition. The Court therefore construes stepper motor in accordance with its ordinary meaning.
"Stepping Motor"

Claim 29 is a dependent claim that follows the independent claim 23. As discussed above, claim 23 describes a "memory device." Id. at 10:25. This "memory device" is further defined in claim 29 as comprising, among other things, "an actuator coupled to the sensor head for positioning the sensor head" and "a stepping motor coupled to the actuator for linearly driving the actuator." Id. at 10:62-66 (emphasis added). The parties' disagreement as to the construction of the term "stepping motor" is minor. Plaintiffs suggest that a "stepping motor" is "a motor that moves in small steps," whereas defendants suggest that it is a motor "that can only position the actuator in discrete steps." Because the definition of "stepping motor" is not discussed in the claims, specification, or anywhere else in the patent, 12 we turn to extrinsic evidenceto aid construction. Phillips, 415 F.3d at 1317.

During the Markman hearing, the parties provided the court with a technology tutorial to explain the relevant scientific terms and principles involved in this dispute. A portion of this presentation was dedicated to stepping motors and the means by which they operate. According to that presentation, stepping motors contain a rotor, the circumference of which is fitted with a series of uniformly sized and spaced teeth, similar to a gear. Each tooth is magnetized. The rotor is connected to a shaft, and is surrounded by a circular housing on which are located a series of electromagnets. Electromagnetic pulses are sent sequentially from each of the electromagnets surrounding the rotor, thereby advancing the rotor tooth-by-tooth.

In the Modern Dictionary of Electronics, a stepping motor is defined in a number of ways, including: "[a] motor whose normal operation consists of discrete angular motions of essentially uniform magnitude, rather than continuous rotation"; "a bidirectional permanent-magnet motor that turns through one angular increment for each pulse applied to it"; and "an electric motor that moves incrementally." Modern Dictionary of Electronics, 735 (7th ed. 1999).

Based on the extrinsic evidence before the court, we find that a person of ordinary skill in the art would understand a "stepping motor" to be an electric motor that is capable of moving only in small, discrete increments. We reject plaintiffs' proposed construction, because it fails to acknowledge that such motors are inherently limited to moving in discrete, incremental steps. Although defendants properly defined the motor as only moving in discrete steps, we disagree with defendants' construction insofar as we find it unnecessary to refer to an actuator when defining the term "stepping motor."

The parties seek construction of the following highlighted term of Claim 4: "Apparatus as claimed in claim 3 where the stop means comprises steps formed in the fins." (‘300 patent, col. 4, ll. 50-51.) P&M construes the term as "a surface or surfaces cut into the fins against which part of the pen may abut" and explains that the steps abut the surface of the pen, thereby preventing it from sliding into the casing and keeping it in position. (Pls. Opening Mem. at 30.) Rose Art construes the word "steps" as protrusions that are as high as they are long. (Def. Pre-Markman Hr'g Br. at 43.) Rose Art has supplied no basis for requiring the steps to be as high as they are long. Consequently, the term is construed as "a surface or surfaces cut into the fins against which part of the pen may abut."
I.

Caterpillar Inc. filed this suit against Detroit Diesel Corporation alleging that Detroit Diesel’s "CruisePower" feature infringes its United States Patent No. 4,914,597 ("’597 patent"). The patent relates to a system providing variable engine power while using vehicle cruise control; the claim at issue--Claim 1--involves a method of operating a vehicle engine with cruise control by use of a fuel delivery system that controls the rate of fuel delivery by responding to a command signal generated through the retrieval of sets of data from memory, the set retrieved depending on whether the cruise control is "engaged."

Claim 1 of the ‘597 patent provides the following:

1. A method of operating a vehicle engine (12) equipped with a cruise control (44) which is engageable to control the speed of the vehicle (38) in response to a set speed wherein the engine includes a fuel delivery system (14) which is responsive to a command signal to in turn control the rate of fuel delivery to the engine, comprising the steps of:

   providing a memory (86) having stored therein two sets of data representing two different fuel delivery limit curves wherein each fuel delivery limit curve defines predetermined fuel delivery limits as a function of engine speed;

   determining when the cruise control (44) is engaged;

   retrieving one of the sets data from the memory (86) representing one of the fuel deliver limit curves when the cruise control (44) is engaged;

   retrieving the other set of data from the memory (86) representing the other fuel delivery limit curve when the cruise control (44) is not engaged; and

   using the retrieved data to develop the command signal.

The parties agree that under the Markman decision, the court must determine the meaning of Claim 1 as a matter of law before the issue of infringement may be resolved with reference to the claim's meaning. In construing a patent as a matter of law, the court considers the claim itself, the specification, and the prosecution history ("file wrapper"). Markman v. Westview Instruments, 52 F.3d 967, 979 (Fed. Cir. 1995) (citing Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1561 (Fed. Cir. 1991)). The court is to construe the claim's language; the court cannot narrow or broaden the scope of a claim to give the patent owner something different than what is set forth. E.I. DuPont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988); Autogiro Co. of America v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 396 (Ct. Cl. 1967). The court may also consider extrinsic evidence as an aid in understanding the meaning of the claims' language, Markman v. Westview Instruments, 52 F.3d at 980, though extrinsic evidence may not be used "for the purpose of varying or contradicting the terms of the claims." Id. 52 F.3d at 981.

--- Footnotes ---

1

Extrinsic evidence consists of all evidence external to the patent and prosecution history, including expert and inventor testimony, dictionaries, and learned treatises. This evidence may be helpful to explain scientific principles, the meaning of technical terms, and terms of art that appear in the patent and prosecution history. Extrinsic evidence may demonstrate the state of the prior art at the time of the invention. It is useful to show what was then old, to distinguish what was new, and to aid the court in the construction of the patent.

… The court may, in its discretion, receive extrinsic evidence in order to aid the court in coming to a correct conclusion as to the true meaning of the language employed in the patent.

52 F.3d at 979 (internal quotation omitted).
A claim must be read in light of the entire specification, which contains an explanation of the invention that must enable one of ordinary skill in the art to make and use the invention. "The description may act as a sort of dictionary, which explains the invention and may define terms used in the claims." 52 F.3d at 979. Although the patentee is granted license to define his terms, 2 any special definition assigned to a word must be clearly defined in the specification. Id. (citing Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388 (Fed. Cir. 1992)); see Quantum Corp. v. Rodime, PLC, 65 F.3d 1577, 1580 (Fed. Cir. 1995) ("The words of a claim will be given their ordinary meaning to one of skill in the art unless the inventor appeared to use them differently."), cert. denied, 134 L. Ed. 2d 666, 116 S. Ct. 1567 (1996). The claim defines the scope of the invention, SRI Int'l v. Matsushita Elec. Corp. of Am., 775 F.2d 1107, 1121 (Fed. Cir. 1985) (en banc), and although the specification may aid in divining the true meaning of the claim, the court cannot read into a claim a limitation that appears in the specification but not the claim. Minnesota Mining & Mfg. Co. v. Johnson & Johnson Orthopaedics, 976 F.2d 1559, 1566 (Fed. Cir. 1992); E.I. DuPont de Nemours, 849 F.2d at 1433. References to a preferred embodiment, such as those in the specifications or drawings, are not claim limitations. Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1988); Raytheon Co. v. Roper Corp., 724 F.2d 951, 957 (Fed. Cir. 1983). And although the patent's prosecution history is relevant to determining claims' meaning, 52 F.3d at 980 (citing Graham v. John Deere Co., 383 U.S. 1, 33, 15 L. Ed. 2d 545, 86 S. Ct. 684 (1966)), it similarly cannot change the scope of the claims, 52 F.3d at 980.

2 The Court of Claims described the reasoning for this in Autogiro Co. of America v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 397 (Cl. Ct. 1967):

An invention exists most importantly as a tangible structure or a series of drawings. A verbal portrayal is usually an afterthought written to satisfy the requirements of patent law. This conversion of machine to words allows for unintended idea gaps which cannot be satisfactorily filled. Often the invention is novel and words do not exist to describe it. The dictionary does not always keep abreast of the inventor. It cannot. Things are not made for the sake of words, but words for things. To overcome this lag, patent law allows the inventor to be his own lexicographer ….
A patent specification contains a description of the invention, a description of how to make and use the invention that would allow one reasonably skilled in the art to make and use it, and a description of the "best mode" contemplated by the inventor for carrying out the invention. 35 U.S.C. § 112(1). The specification must conclude with "one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention." 35 U.S.C. § 112(2). Patent claims may be drafted in "functional" language, which "describes an invention in terms of what it accomplishes rather than in terms of what it is." 2 Chisum, Patents, § 8.04 at 8-53. Functional language is by its nature broad, and may run afoul of the Patent Act's requirement that a patent claim "particularly point[] out and distinctly claim[] the subject matter which the applicant regards as his invention." 35 U.S.C. § 112, P 2 (based on 35 U.S.C., 1946 ed., § 33).

Just such a situation occurred in Halliburton Oil Well Cementing Co. v. Walker, 329 U.S. 1, 91 L. Ed. 3, 67 S. Ct. 6 (1946), in which the Supreme Court held that a claim drafted as a "means-plus-function" was invalid. The functional language of the patent at issue in Halliburton 4 described a resonator in relation to the rest of the apparatus as "means associated with said pressure responsive device for tuning said receiving means to the frequency of echoes from the tubing collars of said tubing section to clearly distinguish the echoes of said couplings from each other." 329 U.S. at 8-9. "The language of the claim," the Supreme Court explained, "thus describes this most crucial element in the 'new' combination in terms of what it will do rather than in terms of its own physical characteristics or its arrangement in the new combination apparatus." Id. at 9. It was this "broadness, ambiguity, and overhanging threat of the function claim" that troubled the Supreme Court:

What he claimed in the court below and what he claims here is that his patent bars anyone from using in an oil well any device heretofore or hereafter invented which combined with the Lehr and Wyatt machine [(the prior art)] performs the function of clearly and distinctly catching and recording echoes from tubing joints with regularity. Just how many different devices there are of various kinds and characters which would serve to emphasize these echoes, we do not know. The Halliburton device, alleged to infringe, employs an electric filter for this purpose. In this age of technological development there may be many other devices beyond our present information or indeed our imagination which will perform that function and yet fit these claims. And unless frightened from the course of experimentation by broad functional claims like these, inventive genius may evolve many more devices to accomplish the same purpose. Yet if Walker's blanket claims be valid, no device to clarify echo waves, now known or hereafter invented, whether the device be an actual equivalent of Walker's ingredient or not, could be used in a combination such as this, during the life of Walker's patent.

329 U.S. at 12 (citations omitted).

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - -

4 The patent in suit in Halliburton involved "an apparatus designed to facilitate the pumping of oil out of wells which do not have sufficient natural pressure to force the oil to gush." 329 U.S. at 3. The patent at issue improved over the prior art by adding a mechanical acoustical resonator to make an accurate measure of the distance from the well top to the fluid surface. Id. at 4.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - -

In 1952 Congress reacted to the Halliburton decision by enacting paragraph six of § 112 (then paragraph 3), which provides that "an element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112(6). As explained in Greenberg v. Ethicon Endo-Surgery, Inc.,:

The record is clear on why paragraph six was enacted. In Halliburton Oil Well Cementing Co. v. Walker, 329 U.S. 1, 91 L. Ed. 3, 67 S. Ct. 6 (1946), the Supreme Court held invalid a claim that was drafted in means-plus-function fashion. Congress enacted paragraph six, originally paragraph three, to overrule that holding. In place of the Halliburton rule, Congress adopted a compromise solution, one that had support in the pre-Halliburton case law: Congress permitted the use of purely functional language in claims, but it limited the breadth of such claim language by restricting its scope to the structure disclosed in the specification and equivalents thereof.

91 F.3d 1580, 1582 (Fed. Cir. 1996) (citations omitted); see also 2 Chisum, Patents, § 8.04[1] at 8-62 - 8-63. 5 The court in
Motorola, Inc. v. Interdigital Technology Corp., 930 F. Supp. 952, 963 (D. Del. 1996), described this simple example regarding the effect of paragraph 6: "If a patent contains a means-plus-function limitation claiming a 'means for fastening' and the specification discloses a 'button' as a possible fastening means, under Markman a court must resolve any disputes regarding both the 1) function of the fastening means, and 2) the meaning of the word 'button,' as a matter of law."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 

5 Halliburton Oil Well Cementing Co. v. Walker appeared to set an unreasonably high standard of definiteness for patent claims. Claim language in a means-plus-function style had been common prior to Halliburton and had received the apparent approval of the Supreme Court in Continental Paper Bag [, 210 U.S. 405, 52 L. Ed. 1122, 28 S. Ct. 748 (1908)]. Halliburton also seemed to run contrary to the prevailing notions that a patentee need not describe in his specification every possible embodiment of the invention and that a patent would include later specific improvements if those improvements "stood on the shoulders" of the first patent. It is not surprising therefore that Congress inserted the third [(now, sixth)] paragraph of Section 112 in the Patent Act of 1952 to dispel some of the implication of the Halliburton case.

B. Paragraph Six Applies to Methods Claims

Though Caterpillar is correct in its observation that case law directly on point is sparse, the court concludes that, contrary to Caterpillar's assertion, paragraph six of § 112 applies to method claims, and not only to apparatus claims. The court's conclusion is based on the statute's plain language, commentary of one of its drafters, case law at the time of enactment of paragraph six and since then, and on Patent and Trademark Office guidelines.

Contrary to Caterpillar's expert's interpretation, paragraph six of § 112 does not define a new and distinct variety of patent claim. Rather, the plain language of paragraph six makes clear that the method it prescribes applies on an element-by-element basis and that it applies to both apparatus and methods claims: "An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof …" (emphasis added). From the statute courts derive the terms "means-plus-function" and "step-plus-function" for functional language contained in apparatus and methods claims respectively.

6 Caterpillar's expert, James M. Amend, asserts in his affidavit that, "depending on the type of patent (e.g. method, means-plus-function, apparatus, etc.), certain statutory and/or common law rules will govern the manner in which the claims of the patent should be construed," and that "because Claim 1 of the 597 patent is a method claim, P6 of 35 U.S.C. § 112 does not apply to the construction of that claim." Amend Aff. (exh. B to Caterpillar's response), P 15.

Commentary by one of paragraph six's drafters supports its application to method/process claims. The Reviser's Notes regarding paragraph six included the following comment by P.J. Federico, then Examiner-in-Chief of the Patent Office:

The last paragraph of section 112 relating to so-called functional claims is new. It provides that an element of a claim for a combination (and a combination may be not only a combination of mechanical elements, but also a combination of substances in a composition claim, or steps in a process claim) may be expressed as a means or step for performing a specified function, without the recital of structure, material or acts in support thereof.

112, 6th Paragraph, 47 Pat. Trademark & Copyright J. (BNA) 571, 571 (1994); see also Practising Law Institute, The Winning Mechanical Claim, 426 PLI/Pat 231, 331 (1995); Paul M. Janicke, The Crisis in Patent Coverage: Defining Scope of an Invention by Function, 8 Har. J.L. & Tech. 155, 192 n.14 (1994). In Donaldson the court held that paragraph six of § 112 applies not only to courts, but also to the PTO's patent examination process. The guidelines (which were "distributed to patent examiners for guidance on examining practice and procedure" and "incorporated into the Manual of Patent Examining Procedure") begin by setting forth six examples of elements of claims that are written in functional language that invokes paragraph six of § 112. 47 Pat. Trademark & Copyright J. (BNA) at 571. The guidelines' last two examples are elements of process claims from In re Roberts, 470 F.2d 1399 (C.C.P.A 1973), and Ex parte Zimmerley, 153 U.S.P.Q. 367 (Bd. App. 1966), respectively:

(5) reducing the coefficient of friction of the resulting film [step plus function; "step" unnecessary], and

(6) raising the Ph [sic] of the resultant pulp to about 5.0 to precipitate …

The guidelines also provide that "step" and "act" are related in the same way as "means" and "structure." 47 Pat Trademark & Copyright J. (BNA) at 573.

------------------------------------------ Footnotes ------------------------------------------

7 The court is mindful of the Federal Circuit's warning in In re Donaldson, Inc., 16 F.3d 1189, 1193 n.3 (Fed. Cir. 1994), that Mr. Federico's comments do not constitute legislative history per se because Mr. Federico, though a textual author of the 1952 Patent Act's provisions, was not a legal author, and so was "merely stating his personal views." Lawrence Kass, Comment, Computer Software Patentability and the Role of Means-Plus-Function Format in Computer Software Claims, 15 Pace L. Rev. 787, 852-853 (1995). The Donaldson court's warning, however, was made in the context of a different issue (whether application of paragraph six of § 112 is appropriate during patent examination). With respect to the application of paragraph six, the United States Court of Customs and Patent Appeals expressed its agreement with Mr. Federico's interpretation of paragraph six as applying to "not only a combination of mechanical elements, but also a combination of substances in a composition claim, or steps in a process claim." Application of Fuetterer, 50 C.C.P.A. 1453, 319 F.2d 259, 264 (C.C.P.A. 1963).

------------------------------------------ End Footnotes ------------------------------------------

In Roberts the Court of Customs and Patent Appeals reversed the examiner's rejection of four method claims. 470 F.2d at 1403. The examiner's rejection was based on the claims' functional language; the examiner thought the step of "reducing the coefficient of friction--to below about 0.40' defined a result but failed to identify the specific act or acts required to produce the result claimed." Id. at 1402. The court disagreed with the examiner's conclusion because "the [sixth] paragraph of [section 112] specifically allows the use of functional language to define claim limitations." Id. at 1402. "The absence in the claim of specific steps which would bring about the desired friction property is no defect. The claims define the limits of the claimed invention, and it is the function of the specification to detail how this invention is to be practiced." Id. at 1403. In Zimmerley, the Patent Office Board of Appeals reversed a rejection of a method claim for failing to particularly point out and distinctly claim the invention; specifically, the examiner thought that the claim element of "raising the pH level of the resultant pulp to about 5.0 to precipitate dissolved molybdenum as molybdenum trihydroxide" should have recited a specific way of raising the pH level. 153 U.S.P.Q. at 369. The court found the examiner's rejection improper because paragraph six of § 112 "sanctions functionally defined steps in claims drawn to a combination of steps." Id. at 369.

In In re Cohn, 58 C.C.P.A. 996, 438 F.2d 989 (C.C.P.A. 1971), the court noted that paragraph six of § 112 applies to functional language in a method claim, though it went on to find inexplicable inconsistencies within the claims at issue and affirmed the examiner's rejection of the patent as indefinite under the second paragraph of § 112. 438 F.2d at 991 ("It is true that claim language which expresses performing particular steps until a given result or state is reached, or a given condition obtained, may be proper under § 112, [sixth] paragraph.").

From Roberts, Zimmerley, and Cohn, the court concludes that § 112 applies to functional methods claims where the element at issue sets forth a step for reaching a particular result, but not the specific technique or procedure used to achieve the result. Such an interpretation is consistent with the statute's plain language, which exempts from the purview of § 112(6) an element in a claim for a combination that is expressed as a means or step for performing a function with the recital of
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

supporting acts. 8

8 Indeed, the Federal Circuit has found § 112(6) inapplicable in situations where an element's language is functional, but
some recitation of structure exists and the "means" is not tied to the function. York Products, Inc. v. Central Tractor Farm &
Family Center, 99 F.3d 1568, 1574 (Fed. Cir. 1996).

The Federal Circuit's treatment of means-plus-function language reveals that paragraph six's application is not triggered
simply by the use of functional language or the magic words "means for ..." or "step for ...." 9 In Greenberg v. Ethicon
Endo-Surgery, Inc., 91 F.3d 1580 (Fed. Cir. 1996), the Federal Circuit found that the district court erred in applying § 112(6)
9 For a broader view of the application of § 112(6) to method claims, see Kenneth R. Adamo, Drafter's Dilemma: Means
Plus Function and Guidelines and Hilton Davis. 78 J. Pat & Trademark Off. Soc'y 367, 389 (1996) ("It is fundamental that
nearly all steps recited in process claims fall within this provision [§ 112, para. 6] of the Patent Statute," (citations omitted)).
Though the Federal Circuit has not directly addressed the issue, the Federal Circuit has clearly not adopted such an
expansive view of the application of § 112(6) to method claims.

9 For a broader view of the application of § 112(6) to method claims, see Kenneth R. Adamo, Drafter's Dilemma: Means
Plus Function and Guidelines and Hilton Davis. 78 J. Pat & Trademark Off. Soc'y 367, 389 (1996) ("It is fundamental that
nearly all steps recited in process claims fall within this provision [§ 112, para. 6] of the Patent Statute," (citations omitted)).
Though the Federal Circuit has not directly addressed the issue, the Federal Circuit has clearly not adopted such an
expansive view of the application of § 112(6) to method claims.

Greenberg thus teaches that an element's language is not dispositive of whether § 112(6) applies, see York Products, Inc. v.
Central Tractor Farm & Family Center, 99 F.3d 1568, 1574 (Fed. Cir. 1996) ("Mere incantation of the word 'means' in a
clause reciting predominantly structure cannot evoke section 112, P 6."), and that the court should consider whether the
functional term has a "reasonably well understood meaning in the art," and the drafter's intent, as may be evidenced by the
language, reference to other elements or claims, and the prosecution history.

C. Section 112(6) Does Not Apply to the Elements of Claim 1 of the '597 Patent

Applying the factors discussed above to the elements of Claim 1, the court concludes that § 112(6) is not applicable. The
elements of Claim 1 of the '597 patent are written as steps-plus-functions, which support an intent to invoke § 112(6): "steps
of: providing a memory ... determining when the cruise control is engaged; ... retrieving one of the sets [of] data ...;
retrieving the other set of ...; and using the retrieved data..." That factor; however, is not determinative, and the remainder
of the factors counsel the court not to apply § 112(6). Nothing in the prosecution history suggests an intent to invoke §
112(6), see ex. D to Caterpillar's response, and the elements at issue in Claim 1 are not result-oriented, as were those in
Roberts, Zimmerley, and Cohn, in which the Federal Circuit discussed the application of § 112(6) to method or process

- 4463 -

PUBPAT
The elements of Claim 1 involve the actions of "providing," "determining," "retrieving," and "using," which do not merely describe an achieved result, but are specific acts in themselves. The acts set forth in Claim 1's elements are "functional" only in the manner in which all acts are functional, and nothing before the court suggests that the acts set forth in the claim lack a "reasonably well understood meaning in the art." See Greenberg, 91 F.3d at 1583.

1. a balloon

This term appears in the '364 patent, but not in the '939 patent. The plaintiffs propose that this term carry its plain meaning. The defendants propose "a balloon sterilized by the sterilization process disclosed at 10:66-11:9 of the '364 patent, which consists of (1) a preconditioning step at a temperature about 35 to about 45 [degree] C and a relative humidity of about 55% for about 15 hours, (2) then an ethylene oxide treatment step at a temperature of about 35 to about 45 [degree] C and a relative humidity of about 55% with ethylene oxide for about 6 hours, and (3) then an aeration step at a temperature of about 35 to about 45 [degree] C for about 22 hours in order to permit the ethylene oxide to dissipate."

The plaintiffs argue that the defendants seek to improperly import two limitations into the claim: (1) that the balloon must be sterilized, and (2) that the sterilization must occur by the sterilization method described in the specification.

According to the defendants, the proper claim construction for "balloon" (as well as "sterilized balloon" in the '939 patent, discussed infra) should include the sterilization process described in the specification ("the Anderson Process"). Defendant's Response Brief at 15-21. Numerous citations in the specification support the defendants' position that the "Anderson Process is critical." Id. at 15 (citing the '364 patent at 11:14-17 (the Anderson Process is "an important factor in determining the final physical characteristics of the balloons and balloon catheters of this invention"); 10:51-54 ("[i]n order to preserve a balloon's distensibility, elastic stress response, [and] wall tensile strength..., the balloon formed must [] be subject to" the sterilization process disclosed); and 11:17-22 (the sterilization disclosed is "necessary to ensure a clinically useful and sale[sic] finished balloon and balloon catheter with an overall advantageous combination of physical properties..."))).

The defendants also point to statements made during the prosecution of the '939 patent that further express the importance of the sterilization process. For example, in remarks made to distinguish prior art the applicants stated that the balloons in the prior art "are not prepared by substantially the same process disclosed in Applicants' specification, namely the sterilization steps of the present invention, which give rise to the novel and unobvious properties of the claimed invention...." Wu Decl. Ex. 11 ['939 file history] at MEQBC00004242-43.

The defendants further support their construction by pointing to a recently decided Federal Circuit case, Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361 (Fed. Cir. 2007) (reading a process limitation into a claim for a product formed by the process). In Andersen, the court noted that the "specification [] indicates that the claimed physical properties of the composite structural members are attributable to the process that is used to make them." Id. at 1372. Since the '364 specification describes the use of the sterilization process as a requirement rather than a preference, the defendants argue that the term "balloon" should be limited to the process that created its properties. Id. at 1372-73.

The defendant further argues that the prosecution history is analogous to that in the Andersen case. As in this case, the applicant of the patent at issue in Andersen "clearly disclaimed structural members made through a direct extrusion process." Id. at 1373-74. Here, the applicants clearly distinguished their invention from those balloons that underwent traditional sterilization.

At oral argument the plaintiffs argued that the term "balloon" alone is insufficient to provide a textual reference in the claim to associate the sterilization process. See MBO Laboratories, Inc. v. Becton, Dickson & Co., 474 F.3d 1323, 1330-31 (Fed. Cir. 2007). The MBO Labs court stated that "[n]one of the disputed terms... can be reasonably be construed to impose the simultaneously-safety requirement." Id. at 1330. The court, however, recognized that the "patentee [in MBO Labs] has clearly indicated via the specification and the prosecution history that the invention provides, as an essential feature, immediate needle safety upon removal from the patient." Id.

The court agrees that the term "balloon" does not provide sufficient textual reference to include the sterilization process.
Accordingly, the term "balloon" does not need to be construed.

2. **a sterilized balloon**

This term appears in the '939 patent, but not in the '364 patent. The plaintiffs propose that this term carry its plain meaning. The defendants propose the same construction they advance for the term "balloon," above. The parties present nearly identical arguments for this limitation as they did for the term "balloon."

As an initial matter, the distinction between the groupings in the Anderson case does not apply to the distinction between "balloon" and "sterilized balloon." In Anderson, two groups of claims were at issue. The first group, or Group I, claimed "an intermediate composite capable of being extruded into structural members." Anderson, 474 F.3d at 1371. The second group, or Group II, claimed "the extruded structural members themselves." Id. The Federal Circuit held that the district court had properly limited the term "composite composition" in Group I to be in the form of either pellets or linear extrudate. The district court reasoned that because the Group II claims are directed to finished products they should not be limited to the characteristics of an intermediate material. The Federal Circuit, however, found that the district court erred by not also construing the term "composite structural member" in Group II to include "an intermediate step of pelletization or linear extrusion" given the intrinsic evidence. Id. at 1375. In this case, both the "balloon" claims and "sterilized balloon" claims are directed to finished products.

Rather, the issue before this court is whether there is sufficient "textual reference in the actual language of the claim with which to associate a proffered claim construction." Johnson Worldwide Assocs., Inc. v. Zebeco Corp., 175 F.3d 985, 990 (Fed. Cir. 1999). Unlike the term "balloon," the term "sterilized balloon" provides a clear association with the sterilization process described in the specification. With the addition of the term "sterilized," the claim explicitly recites a term in need of definition. See MBO Labs, 474 F.3d at 1300-31 (citations omitted). The specification unequivocally teaches the necessity of the Anderson Process of sterilization. See, e.g., '364 patent at 11:17-22 (the sterilization disclosed is "necessary to ensure a clinically useful and sale[sic] finished balloon and balloon catheter with an overall advantageous combination of physical properties").

For these reasons, the court adopts the defendants' construction for "sterilized balloon." 3

--- Footnotes ---

3 The court draws this distinction between the terms "balloon" and "sterilized balloon" after careful study of, and reliance on, both MBO Laboratories, Inc. v. Becton, Dickson & Co., 474 F.3d 1323 (Fed. Cir. 2007) and Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361 (Fed. Cir. 2007). The Federal Circuit issued these opinions within two days of each other, and the panels included a common judge.

H. Disputed word: "stitches"

The disputed term is located in Claim 12. The parties disagreement turnson the specificity required of the term "stitches." Plaintiff proposes this claim should be interpreted as "material that repeatedly pierces through at least two things and, in doing so, ties the two things together." Defendant proposes this claim should be interpreted as "a length of thread that repeatedly pierces through the loop of tape and the bag to tie them together."

Plaintiff argues the patent claim language justifies a broad definition. Plaintiff argues the patent never identifies or specifies the material used for stitching. Plaintiff argues the word is "material-independent," as opposed to other places in the patent where the material is identified, such as "fiber reinforced filament tape." Defendant states the patent identifies stitches in Figure 3 as reference number 56 and in Figure 6 as reference number 98. Defendant argues Figure 3 specifically shows the stitches as a length of thread. Defendant argues the patent examiner, in rejecting Claim 8, states that the sewing would include fiber. (Def. Ex. C. at 10.)
Both parties agree the stitches must pierce through materials to tie the materials together. The point of contention is what material must be used to make the stitches. The patent does not identify the material that must be used to make the stitches. No limitation on the material used for the stitches should be imported from the prosecution history. The patent examiner did not reject Claim 8 because of the material used to make the stitches. Accordingly, Plaintiff's construction of the claim is persuasive and supported by the intrinsic evidence. The claim at issue is interpreted to mean "material that repeatedly pierces through at least two things and, in doing so, ties the two things together."

The plaintiff proposes "an elongated thin metal structure other than the guide wire that is positioned within the catheter shaft and imparts stiffness." The defendant proposes "a solid, continuous metal that imparts stiffness to at least the proximal portion of the outer catheter body."

The plaintiff argues that one of ordinary skill in the art would understand that a "stiffening wire" means "an elongated thin metal structure." The plaintiff also argues that nothing in the patent requires that the stiffness be specific to "the proximal portion of the outer catheter." Specifically, the plaintiff points to the specification which states that the stiffness is imparted "to the catheter" and that stiffness can also be provided to the "distal portion of the catheter." ‘358 patent 2:37-41, 5:1-3.

The defendant argues that the stiffening wire must extend through the proximal portion of the catheter to be effective. According to the defendant, its proposed construction, and not the plaintiff's proposal, would meet the requirement that the stiffening provide "strength to the proximal portion of the catheter." ‘358 patent, 2:37-41. The defendant also argues that the stiffening wire needs to be solid metal because hollow tubes were not contemplated as part of the invention.

The Court agrees with the plaintiff that there is no need to include a limitation regarding stiffness at the proximal portion of the outer catheter body. The plaintiff, however, does not appear to dispute the defendant's proposal that the "stiffening wire" must be solid. Accordingly, the Court construes "stiffening wire" to mean "a thin and elongated solid metal structure that imparts stiffness to the catheter." The Court declines to construe the remainder of the phrase.

The plaintiffs propose "a thin and elongated metal structure that imparts stiffness to the catheter." The defendants propose "a thin and elongated solid metal structure that imparts stiffness to the catheter."

After carefully considering the arguments raised by the parties in this case, the court is not persuaded to alter its construction from the Cordis case. See Cordis Order at 8-10. Accordingly, "stiffening wire" means "a thin and elongated solid metal structure that imparts stiffness to the catheter."

Plaintiffs' proposed construction of "stockinette member" is "a closely knit tubular member formed of closely knit threads." Defendants would modify plaintiffs' construction to include: "closely knit threads forming rows of regular loops and having a closer knit and smaller opening than the netting arrangement."

Plaintiffs contend that defendants "agree that the proposed definition offered by the plaintiffs is found in the claims"
(Plaintiff's response to defendants' opening brief at 7) but by inserting additional language in their construction, defendants are attempting to impermissibly narrow the construction and interject language used exclusively in a prior art, the '057 Lombardi patent. The dispute surrounding the construction is the "terminology of forming rows of regular loops, having a closer knit and smaller openings than the netting arrangement." (Markman Tr. at 66. (emphasis added)) Plaintiffs argue that the only limitations contained within the claim are that the stockinette member be (1) knit, (2) closely knit, and (3) have a first-stretch, i.e., greater stretch capacity, than the netting arrangement. (Markman Tr. at 30.) The Court agrees. The unambiguous language of the claim does not require "regular loops" or any particular stitch be used in the stockinette member.

But defendants contend that the term "rows of regular knit" is necessary for the proper construction of the term "stockinette member" based on the prosecution history wherein plaintiffs distinguished their invention over the prior art of Lombardi. Plaintiffs' Office Action Response, dated August 9, 1994, states with reference to Figure 4 that "the top of the long loop of yarn 42 in wale 3, row 25, being separated from the special yarn [the netting arrangement] in row 27 by one row 26 of regular loops (i.e., loops of the regular yarn)." (Defendants' Exh. B 151.) Based on this language, defendants contend that the stockinette member must be made of regular loops of regular yarn in order to differentiate the stockinette member from the netting arrangement.

Defendants are attempting to impermissibly narrow the plain and ordinary meaning of the claim term. Plaintiffs have not explicitly disclaimed the plain meaning of "stockinette member" in the specification or prosecution history. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) (requiring "words or expressions of manifest exclusion or restriction" before broad terms in a claim will be read narrowly in light of a narrow specification (quoting Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002)).

With respect to the phrase "closer knit and smaller openings than the netting arrangement," defendants note that in order for the stockinette member to have a greater stretch capacity and to form a shield as set forth in the "whereby" portion of Claim 1, the stockinette must have a closer knit and smaller openings than the netting arrangement. The claim language requires that the stockinette member be "closely knit" - a term that is not ambiguous. Further, there is nothing in the claim language or specifications to suggest that smaller openings are necessary for the stockinette member to function as intended.

The Court construes "stockinette member" as "a closely knit tube."

3804

A. "A stop"

The parties disagree as to the proper construction of "a stop" as that term is used in all the claims of the '191 patent. Fujinon contends that "a stop" should be construed as "an element with a hole or opening that blocks or limits light." Motorola contends, by contrast, that "a stop" is "the aperture stop." I recommend that the Court adopt Fujinon's construction, though I reach that conclusion through a different process than Fujinon proposes.

I start with the language of the claim itself. Most important is the fact that nowhere do any of the claims of the '191 patent use the term "aperture stop." Instead, claim I (on which all of the other claims depend) states that the invention has "a stop."

This is crucial because, as both parties agree, in the field of optical design the term "a stop" applies to multiple types of stops and is not limited just to "aperture stops." That is, one of ordinary skill in the art of optical design would understand that "stop" denotes a genus, whereas "aperture stop" is a particular species within this broader genus. Other types of "stops" that are pertinent to this art include "glare stops" and "field stops." 3

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

3 See, e.g., D.I. 66 Ex. 5, Warren J. Smith, Modern Optical Engineering 141 (3d ed. 2000)(hereinafter "MOE")("In every optical system, there are apertures (or stops) which limit the passage of energy through the system.... One of these apertures will determine the diameter of the cone of energy which the system will accept from an axial point on the object. This is termed the aperture stop .... Another stop may limit the size or angular extent of the object which the system will image.

- 4467 -
Turning next to the specification, 4 I conclude that the specification confirms that the inventor claimed the genus of "a stop" in the claims and did not narrow his claim to just "aperture stops." It is true, as Motorola emphasizes, that the inventor used "the stop" to refer to an "aperture stop" when describing prior art, see '191 patent, col. 1 lines 29-38 (JCCC at M00425); see also Markman Hearing Transcript (D.I. 81 and hereinafter "Tr.") at 29-33; and when describing a preferred embodiment of the patent, '191 patent, col. 5 lines 36-38 (JCCC at M00427). But the inventor did not carry this limitation into the claim itself. In other words, in the portions of the specification on which Motorola relies, the inventor is describing prior art or he is disclosing a preferred embodiment of his invention - but he is not there limiting his claim to only those embodiments in which the claimed "stop" is "the aperture stop." Even if the only "stop" in such prior art or preferred embodiment was an "aperture stop," it does not follow that when the inventor turned to the different task of drafting his claims he likewise used "a stop" to refer narrowly to "the aperture stop."

As Fujinon acknowledges, "There is no dispute that the preferred embodiment of the '191 patent discloses an aperture stop." (D.I. 72 at 27) However, the Federal Circuit has "repeatedly warned against confining the claims to those [specific] embodiments" disclosed in the specification. Phillips, 415 F.3d at 1323; see also MBO Labs., Inc. v. Becton, Dickinson & Co., 474 F.3d 1323, 1333-34 (Fed. Cir. 2007) ("[P]atent coverage is not necessarily limited to inventions that look like the ones in the figures. To hold otherwise would be to import limitations onto the claim from the specification, which is fraught with danger.") (internal citation omitted); Liebel-Flarsheim, 358 F.3d at 906 ("Even when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using words or expressions of manifest exclusion or restriction.") (internal quotation marks omitted). To take the discussion of the "stop" in the prior art and preferred embodiment from the specification and import it as a restriction in the claims would run afoul of this principle of claim construction.

In this regard, it is particularly noteworthy that the specification also uses the term "aperture stop." The one (and only one) use of this term appears in the "Detailed Description," at the end of a paragraph that begins ",[a] general description of preferred embodiments of the single focus lens of the present invention will now be described." '191 patent, col. 2 lines 46-65 (JCCC at M00425) The patent states: "The single focus lens further includes a diaphragm stop St between the first lens element G1 and the second lens element G2 that operates as an aperture stop." Id. col. 2 lines 63-65 (JCCC at M00425) Clearly, the inventor knew how to say "aperture stop" when he meant "aperture stop." That he chose in his claim instead to claim "a stop" indicates that he meant to claim something broader than the "aperture stop" that is part of the preferred embodiment. As Fujinon persuasively argues, if the inventor had wanted to limit his patent to the preferred embodiment, which says "aperture stop," "he could easily have done so, but he did not. All he had to say in the claim was aperture stop.... [Y]ou don't use these words lightly in the patent claims. By making a broader term, you expose yourself to prior art.... When you change 'an aperture stop' in the second element to 'stop,' that can have significance." Tr. at 53.
5 Motorola elsewhere recognizes the power of this reasoning. In connection with the '253 patent, in arguing that the disputed term "center" means "geometric center," and not "center region," Motorola observes that the inventor three times said "center" and one time said "center region." (D.I. 71 at 25) From this Motorola concluded: "The inventor knew to say 'center' when he meant 'center.' . . . The inventor knew to say 'central region' when he meant 'central region.'" Id.

This same sole reference to an "aperture stop" is enlightening for another reason as well. In this sentence - "The single focus lens further includes a diaphragm stop St between the first lens element G1 and the second lens element G2 that operates as an aperture stop." - the inventor makes reference to two types of stops: a diaphragm stop and an "aperture stop." The patentee's use of both terms in one sentence shows his awareness of the genus-species relationship between "stop" and "aperture stop," revealing, again, the significance of his choice to use "a stop" in the claim.

As Motorola rightly points out, the process by which Fujinon reaches its proposed construction is flawed. Fujinon begins by selecting a non-technical dictionary (Webster's Third New International Dictionary(2002)), takes one of that dictionary's twelve definitions of "stop," and then modifies this dictionary definition by, among other things, excising the definition's reference to an "aperture stop." D.I. 66 Ex. 1 at 2251 (showing Webster's definition number 3(b)(1) of "stop" is "an opaque barrier for preventing the passage of light through certain portions of an optical system (as at the margin, in the axial zone, or in radial sectors); specif: the aperture of a camera lens"). Fujinon's approach - with its suggestion that a single general dictionary is more probative of the proper construction than the patent's specification - is inconsistent with Phillips. See 415 F.3d at 1321 ("[H]eavy reliance on the dictionary divorced from the intrinsic evidence risks transforming the meaning of the claim term to the artisan into the meaning of the term in the abstract, out of its particular context, which is the specification."). 6

6 Motorola correctly observes that, for purposes of construing, the claims now before the Court, there is no significance to claim 1's use of the term "a stop" as opposed to "the stop." "The first time an element or part is mentioned, it should not be preceded by a definite article ('the') or by 'said.' Instead the indefinite article ('a' or 'an') should be used . . ." (D.I. 71 Ex. B at M2294939 (Robert C. Faber, Landis on Mechanics of Patent Claim Drafting § 23 (4th ed 2002))) Fujinon's U.S. patent counsel admitted that claim 1 would have been rejected by the PTO if it had been written as "the stop." (D.I. 71 Ex. D at 156)

However, Motorola's support for its proposed construction is unpersuasive, procedurally as well as substantively. Motorola contends that the inventor was his own lexicographer, arguing that in the specification the inventor "explicitly define[d]" "a stop" as "an aperture stop." (D.I. 67 at 6) Motorola relies for its contention on the same sentence already quoted above, which contains the specification's only use of the term "aperture stop": "The single focus lens further includes a diaphragm stop St between the first lens element G1 and the second lens element G2 that operates as an aperture stop." 191 patent, col. 2 lines 63-65 (JCCC at M00425) But this sentence does not state a definition of "a stop" with "reasonable clarity, deliberateness, and precision," as is necessary when an inventor wishes to be his own lexicographer. In re Paulsen, 30 F.3d 1475, 1480 (Fed. Cir. 1994).

Two other flaws plague Motorola's lexicographer argument. First, as noted above, the sentence on which Motorola relies appears at the end of a paragraph that begins: "[a] general description of preferred embodiments of the single focus lens of the present invention will now be described." 191 patent, col. 2 lines 47-49 (JCCC at M00425) Hence, the statement on which Motorola relies is a statement about the preferred embodiment, not a definition that extends to the claims. Second, and more importantly, the paragraph immediately after the sentence on which Motorola relies does clearly, deliberately, and precisely define other terms. Indeed, the sentence that begins that next paragraph states: "Definitions of the terms 'lens element' and 'lens component' that relate to this detailed description will now be given." Id. col. 2 lines 66-67 to col. 3 line 1 (JCCC at M00425-26) That paragraph continues by providing several express definitions: "The term 'lens element' is herein defined as . . ." Id. col. 3 lines 1-18; see also id. col. 3 lines 46-48 ("The term 'near the optical axis' is herein defined as . . .") JCCC at M00426). Plainly, the sentence on which Motorola relies is not written in the manner this inventor used to define terms in this patent.

- 4469 -
Motorola also seeks to rely on the post-patent comments of the inventor, from which Motorola divines that the inventor intended "a stop" in claim 1 to mean "the aperture stop." See D.I. 67 at 18 ("[T]here cannot be any better extrinsic evidence on how the skilled artisan would construe the '191 Patent than the inventor's own unbiased words that describe his invention."); see also Tr. at 42 ("[W]e believe the most telling piece of extrinsic evidence is the inventor's own words in later patents."); D.I. 67 at 17-19 (discussing patents issued to '191 inventor, Kenichio Sato, subsequent to his '191 patent, in which Mr. Sato described his '191 patent). However, as Phillips explains, in construing claims "the court looks to those sources available to the public that show what a person of skill in the art would have understood disputed claim language to mean." 415 F.3d at 1314 (emphasis added; internal quotation marks omitted). The undisclosed, subjective intent of an inventor is not, by definition, available to the public, and would not (and could not) be relied on by one of skill in the art. 7

Motorola also contends that it is common for persons of ordinary skill in the art of optical design to use "stop" to refer to "aperture stop." See Tr. at 44; D.I. 77 Ex. J (Warren J. Smith, Practical Optical System Layout 49 (1997)) ("Often the aperture stop is referred to simply as 'the stop.'"). However, this extrinsic evidence is not enough to overcome the persuasive intrinsic evidence, cited above, which convinces me that, in the specific context of the '191 patent's claims, "a stop" refers to the genus of optical "stops" and is not limited to the species of "aperture stops."

Finally, Motorola argues that the disclosed invention cannot work unless the "stop" claimed in claim 1 is an aperture stop. According to Motorola, "The location of the aperture stop is critical in designing a lens system that has the telecentric properties touted by the inventor of the '191 patent." D.I. 67 at 16; see also '191 Patent, col. 4 lines 53-57 (noting "the requirements of orthogonality and telecentricity") (JCCC at M00426); id col. 8 lines 24-54 (claim 1 requiring condition 1 to be satisfied) (JCCC at M00428); '191 Patent Notice of Allowability (examiner referring to "telecentric state") (JCCC at M00426); id col. 8 lines 24-54 (claim 1 requiring condition 1 to be satisfied) (JCCC at M00428); '191 Patent Notice of Allowability (examiner referring to "telecentric state") (JCCC at M00497). Whether or not this is correct as a matter of scientific reality, the relevant legal fact is that the invention claimed in claim 1 need not fulfill every - or even the central - purpose of the inventor's invention. See Acumed LLC v. Stryker Corp., 483 F.3d 800, 805 (Fed. Cir. 2007) ("[Defendant's] argument is essentially an assertion that since the patent says broaching is desirable, the term 'curved' must be construed to cover only embodiments whose curvature allows them to be inserted into a broached hole .... That assertion is flawed: it is an attempt to import a feature from a preferred embodiment into the claims."). However, this extrinsic evidence is not enough to overcome the persuasive intrinsic evidence, cited above, which convinces me that, in the specific context of the '191 patent's claims, "a stop" refers to the genus of optical "stops" and is not limited to the species of "aperture stops."

Motorola also seeks to rely on the post-patent comments of the inventor, from which Motorola divines that the inventor intended "a stop" in claim 1 to mean "the aperture stop." See D.I. 67 at 18 ("[T]here cannot be any better extrinsic evidence on how the skilled artisan would construe the '191 Patent than the inventor's own unbiased words that describe his invention."); see also Tr. at 42 ("[W]e believe the most telling piece of extrinsic evidence is the inventor's own words in later patents."); D.I. 67 at 17-19 (discussing patents issued to '191 inventor, Kenichio Sato, subsequent to his '191 patent, in which Mr. Sato described his '191 patent). However, as Phillips explains, in construing claims "the court looks to those sources available to the public that show what a person of skill in the art would have understood disputed claim language to mean." 415 F.3d at 1314 (emphasis added; internal quotation marks omitted). The undisclosed, subjective intent of an inventor is not, by definition, available to the public, and would not (and could not) be relied on by one of skill in the art. 7

8 See also Tr. at 14-15 (Fujinon arguing: "When you are defining a claim in the patent law, you don't have to ... claim a functioning structure. In fact, the '253 patent, which is very similar, doesn't even claim a stop until the dependent claims.... The claim does not have to meet all the features or all the objectives that are set forth in the specification. All it has to do is claim what the inventor claims is his elements and then determine whether or not that claim is clear.").
Motorola concedes that if the Court concludes, as I have, that the patentee claimed the entire genus of optical stops, then Fujinon's construction is appropriate. See Tr. at 26 (Motorola's counsel stating, "if the Court decides it's going to construe 'stop' to be the broad universe of all possible elements that are disclosed with 'stop' in their title anywhere in the art, then we do not have a problem with the definition that has been proposed by Fujinon"). Accordingly, I recommend that the Court construe "a stop" as "an element with a hole or opening that blocks or limits [CORRECTED] light."

3805

3. "Stop" (422 Patent, Claims 1, 9, 12)

"Stop" is construed as "an impediment or obstacle that blocks forward movement of the cards."

3806

2. Claim 2

Both parties seek construction of the following highlighted term of Claim 2: "Apparatus of claim 1 further comprising stop means within the casing against which a surface of a pen can abut to position the nib of the pen at least partially within the nozzle orifice." ('300 patent, col. 4, ll. 43-46.) This is not a means plus function claim, even though the word "means" is used in the term because the claim element does not recite a function. Envirco Corp. v. Clestra Cleanroom, Inc., 209 F.3d 1360, 1364 (Fed. Cir. 2000) ("If a claim element contains the word 'means' and recites a function, this court presumes that element is a means-plus-function element under § 112, P 6.") (citation omitted). P&M construes "stop means" as "a surface or surfaces within the casing against which the pen abuts." (Pls. Opening Mem. at 29.) Rose Art argues that this claim term should be limited to a structure comprising three fins because that is the structure described in the specification and because prosecution history estoppel prevents the patent from claiming another stop means. (Def. Pre-Markman Hr'g Br. at 42-43.)

The specification states that "the pen is supported centrally within the casing 1 by the fins 12 with a shoulder 15 of the pen body abutting against projecting stops 16 of the fins 12." ('300 patent, col. 3, ll. 21-23.) In the prosecution history of the '300 patent, in order to distinguish claim 1 of the '300 patent from the '886 patent, Bolton informed the patent examiner that:

The invention as defined by claim 1 requires the internal cross-section of the apparatus to be formed "with a plurality of lengthwise-extending locating surfaces between which is retained the pen". In a preferred embodiment, these lengthwise-extending locating surfaces are provided by the fins 12 shown in Fig. 1. As indicated in the Specification at page 6, line 7-8, the fins 12 centralize the pen within the casing for air flow around the pen. The "lengthwise-extending locating surfaces" limitation is not disclosed or suggested by the '886 patent, wherein the pen 9 is retained between end wall 10 (shown in Fig. 6 of the '886 patent) and end wall 17 (shown in Fig. 7 of the '886 patent)."

(Def. Exh. L at 5.) Although Rose Art has correctly noted that the specification describes the stop means in a preferred embodiment as comprising projecting stops on the fins, the Court cannot adopt the construction recommended by Rose Art because that would impermissibly limit the claim to one preferred embodiment described in the specification. Electro Med. Sys., 34 F.3d at 1054. Moreover, prosecution history estoppel does not limit the composition of the stop means to three fins. Bolton mentioned the three fins only as a preferred embodiment of the "lengthwise-extending locating surfaces," not as the only possible form of the stop means. Consequently, the term "stop means" is construed as "a surface or surfaces within the casing against which the pen abuts."

3807

A. The Stop Member

As used in the '290 patent, Toro argues that the "stop member" should be construed as "a physical element that prevents the
swing arm from rotating to a position where it will not return to its median position." The most I can discern from Deere's pre-hearing memorandum is that it is a structure that only allows the swing arm to move in two directions away from the swing arm's median position before being forced back to that position. Deere takes a different approach in its reply memorandum. There it argues that "stop member" should be given its plain and ordinary meaning as being "a member which, in combination with other elements, performs a function of limiting the movement of the swingman (sic)." Deere rightly reasons that since the phrase "stop member" is not a means plus function format, there is no cause to limit its meaning or to define it by reference to functions described in the specification that it may also perform. The Court agrees with Deere's suggestion: "stop member" means a physical structure, which in combination with other elements, performs the function of limiting the movement of the swing arm.

GO BACK

3808

4. "Stopper." The court construes the term "stopper" as a structural limitation to mean "a part of a substrate that may be used to stop the flow of resin to the center hole." Claim 1 recites "wherein the optical information medium further comprises a stopper," thereby implying that the stopper exists as part of the substrate. ('684 patent, col. 22, ll. 20-21) Various dependent claims disclose specific stopper embodiments. Dependent claims 2 through 5 recite "concave/convex portions" and a "ring-shaped groove," and claim 10 recites a "sealant layer." These embodiments, by their very nature, are formed from the substrate. Moreover, claim 18 substantiates this interpretation by reciting the method for fabricating an optical information medium which includes "the step of forming a pair of substrates [that] includes the step of forming a stopper." ('684 patent, col. 24, ll. 1-4) Additionally, the plain language of both the claims and the specification preclude a construction where the stopper must perform the function of preventing resin from protruding into the center hole of the substrates. Claim 6 allows resin to spread to the position of the stopper. Since claim 6 depends on claim 1, claim 1 must be broader than claim 6. As such, claim 1 is not limited to filling the stopper with resin. Likewise, the specification states that resin does not necessarily fill the stopper. (See '634 patent, col. 11, ll. 52-56)

GO BACK

3809

81. The court construes the first additional limitation of claim 24, "a compressed [nitrox] storage assembly," as follows: the assembly contains as many conventional storage vessels (such as a nitrox storage cylinder or a scuba tank) as the operator of the system desires, and it contains an identical number of branch lines, one branch line for each storage vessel. (See '845 patent, col. 6, lines 20-28.)

I. "storm survival kit"

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiff's Proposed</th>
<th>Defendants' Proposed</th>
</tr>
</thead>
<tbody>
<tr>
<td>storm survival kit</td>
<td>A protective barrier device configured to be quickly</td>
<td>A protective element configured to be quickly deployed</td>
</tr>
<tr>
<td></td>
<td>deployed on or within a portion of a structure for protecting</td>
<td>to protect a life.</td>
</tr>
<tr>
<td></td>
<td>an interior portion of the structure from the force of the wind and objects carried thereby.</td>
<td></td>
</tr>
</tbody>
</table>

Defendants argue that the ordinary meaning of the term "survival" is "the continuation of life or existence" and not the protection of manmade structures. 2 Plaintiff counters that such construction "ignores and improperly limits the claim language" because the patentee unequivocally explains in the specification that the invention relates to a protective barrier device to secure not only occupants, but also property.

- - - - - - - - Footnotes - - - - - - - - -

- 4472 -
2 Defendants also rely on (1) the applicant's September 5, 2003 amendment in successor Patent '852's prosecution history stating that claim 10 "recites a kit for use in the interior of a building," and (2) a PTO examiner's August 27, 2001 Notice of Allowability statement in Patent '085's prosecution history, to support their argument that claim 10 should be construed as meaning the device must be deployed in the interior of a building. Defendants cite these two prosecution statements, which represent a consistent point of argument, in their rebuttal statement of other claim terms. The Court concludes that Defendants' arguments based on these prosecution statements are more appropriately reserved for discussion in the next and final claim term sections. Accordingly, the Court addresses these arguments in those sections.

The Court concludes that Plaintiff's construction of this claim term is accurate. A review of the surrounding words of claim 10 itself reveals that the phrase "storm survival kit" contemplates a device for use in "protecting a portion of the interior of a structure" from wind and windborne objects. Patent '085, col.7, Ins. 24-26. Moreover, the specification expressly describes the claimed invention as relating to the "protection of property against high winds" and distinguishes prior art as lacking an inexpensive protective barrier for use in "protecting the occupants and the property." Patent '085, col. 1, Ins. 13-14; col. 1, Ins. 60-63 (emphasis added). The summary of the invention section of the specification again describes the invention as contemplating the provision of "continuous protection for the occupants and the property." Patent '085, col. 2, Ins. 1-4 (emphasis added). Thus, an examination of "storm survival kit" within the context of claim 10's own language, as well as the patent specification, leads to the conclusion that it would be improper to limit this claim to meaning a device to protect a life as urged by Defendants. Instead, viewing the claim language in light of the specification shows that "storm survival kit" encompasses the protection of the interior portion of the structure, including but not limited to persons and property contained therein. Accordingly, the Court adopts Plaintiff's proposed construction of "storm survival kit."

3811

Similarly, the meaning of the terms "stowed" and "retracted position substantially within said housing" is unambiguous and may be determined from the intrinsic evidence of record, including the claim language, specification and prosecution history. American Seating understands the term "stowed" to mean that the anchoring mechanism is put completely out of the way of passengers, such as by use of a bulkhead, when not deployed. Transportation Seating understands the term "stowed" to mean that the anchoring mechanism is put sufficiently out of the way of passengers to prevent usual tripping. The A.R.M. products manufactured by American Seating do not completely stow their anchoring mechanisms as indicated in the Adelsperger Declarations and the drawings depicting the products. The specification language of the patent states that the anchor and belt assemblies are to be stowed "clearly out of a position in which a regular passenger may trip over the structure." ( '325 patent, at col. 5, lines 10-12.) Given also the prosecution history, which tends to show that the application was modified to make clear that the bulkhead feature posed less of a tripping hazard then the prior art in that the relevant assemblies were completely stowed, the Court determines as a matter of law that the patent language means that the anchoring mechanism is completely stowed within the bulkhead and is completely out of the way of passengers.

3812

The parties also dispute the meaning of the claim terms "stowed" and "substantially within." With respect to the term "stowed," TSI argues that the term does not require that the anchor member be completely contained by the bulkhead. Rather, the anchor member can be partially contained and still be considered "stowed." While the term is therefore somewhat ambiguous, the specification makes clear the meaning of "stowed" in the context of the invention. See Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325, 63 USPQ2d 1374, 1381 (Fed. Cir. 2002) ("The specification may assist in resolving ambiguity where the ordinary and accustomed meaning of the words used in the claims lack sufficient clarity to permit the scope of the claim to be ascertained from the words alone."). When the anchor member, including the strap assembly, is in the "stowed position" it is "stored away clearly out of a position in which a regular passenger may trip over the structure." '325 Patent, col. 5, ll. 8-12. The figures further show that when the anchor member is stowed, it is completely contained within the bulkhead D. We conclude that claim 24 requires the bulkhead to stow the anchor member by containing it at least enough to prevent a passenger from tripping over it, if not altogether containing the anchor member.
Like wise, "substantially within" as used in claim 31 is ambiguous to the extent it is unclear how much of the anchor member must be contained within the bulkhead housing to be considered "substantially within" the housing. See, e.g., LNP Eng'g Plastics, Inc. v. Miller Waste Mills, Inc., 275 F.3d 1347, 1354, 61 USPQ2d 1193, 1198-99 (Fed. Cir. 2001) (construing the phrase "substantially completely wetted"); York Prods. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1572-73, 40 USPQ2d 1619, 1622-23 (Fed. Cir. 1996) (construing the phrase "a substantial part of the entire height"). The natural meaning of this claim language would be that most, but not necessarily all, of the anchor member must be contained within the housing. See York Prods., 99 F.3d at 1573, 40 USPQ2d at 1622 (stating that "the modifier 'substantially' conveys that the ridge members extend over most of the 'entire height'"); LNP Eng'g, 275 F.3d at 1354, 61 USPQ2d at 1199 (stating that "substantially completely wetted" means "largely, but not necessarily wholly, surrounded by resin"). The specification further explains that the reason why the anchor member should be contained within the housing is to prevent tripping. We therefore conclude that claim 31 requires the bulkhead housing to contain most of the anchor member and to such an extent as to prevent a passenger from tripping over the anchor member.

**C. "Straight" as used in Claims 416:1, 5, and 8**

Alden argues that "straight" means "like a straight line, not curved." Alden Br. at 7. Eazypower would construe the term as "a single, uninterrupted, and continuous straight line." Eazypower Br. at 15. The real issue seems to be whether a serrated scraping edge is "straight."

1. Claim Language

The language of claims 416:1, 5, and 8 are set forth above in the Court's discussion of the term "point." Claim 416:1 refers to "a distal straight scraping edge." DX B, col 3, Ins 56-57. Claim 416:8 uses the same phrase. Id. col 4, ln 65. Claim 416:5 describes "a straight scraping edge." Id. col 4, ln 20. Nothing about the claim language compels the Court to accept either proposed construction.

2. Specification

Alden points to the "Detailed Description of Embodiments" in the '416 patent, which states that the scraping edge is "preferably a straight line from periphery to axis." DX B, col 2, Ins 18-19. The rearward edge is described in similar fashion, but without the term "preferably." Id. col 2, Ins 24-25. This adds nothing to the Court's analysis.

Eazypower argues that all of the embodiments in the '416 patent show a continuous, uninterrupted line representing the scraping and rearward edges. DX B, figs 4, 6, and 8. The Court agrees that the figures show straight lines, but will not limit the claims to the specific embodiments shown. Further, for the reasons the Court refused to interpret the Richards patent based solely on its drawings in the context of the Court's construction of "point," the Court will not rely on these patent drawings to construe "straight."

3. Prosecution History

Alden argues that a piece of prior art cited by the examiner against the '730 patent, patent number 5,570,978 ("Rees patent") shows serrations, and therefore the term "straight," as used in the '730 and '416 patents, includes serrated edges. Like the '416 patent, the '730 patent describes a "distal straight scraping edge" and "straight scraping edge," so the Court considers the prosecution history of the "730 patent in construing the same terms in the '416 patent.

It is clear from the face of the '730 patent that the examiner cited the Rees patent, but not the reasons. DX A (cover sheet). Alden has not explained why Rees was cited nor pointed the Court to any portion of the extensive file history in which Rees was discussed. At oral argument, Alden admitted that Rees was not specifically applied by the examiner. Further, Alden has failed to point out what in the Rees patent shows serrations. Therefore, the Court gives no weight to the Rees patent.

4. Extrinsic Evidence

Eazypower cites the Merriam Webster Online Dictionary definition of "straight" in support of its construction: "free from
curves, bends, angles, or irregularities, straight hair, straight timber"; "generated by a point moving continuously in the same
direction and expressed by a linear equation, a straight line, the straight segment of a curve." Merriam Webster Online
among other inapplicable definitions, as: "free from curves, bends, or angles: having no irregularities in course"; "of,
relating to, or constituting a one-dimensional continuum that is determined throughout its length by any two points included
in it: taking a course like that of a taut uninterrupted cord made fast at opposite ends: progressing or projected in an
unvarying direction." Webster's Third New International Dictionary at 2254 (1981). These definitions support Eazypower's
position that a "straight" edge is uninterrupted and continuous, which would not include a serrated edge.
5. Construction

Neither the claims nor the specification clearly define the term "straight." The prior art that Alden cites is unconvincing.
Therefore, the Court is left with only a dictionary definition, which supports Eazypower's construction. "Straight," as used
in claims 416:1, 5, and 8, means "a single, continuous, uninterrupted straight line."

4. Strand

Plaintiffs' proposed construction of "strand" is "a yarn or yarns used in forming the lateral and longitudinal structures of the
netting arrangement." Defendants' construction of "strand" is "elasticized or non-elasticized materials including yarn that is
heavier than the yarn used to form the stockinette member and having a longitudinal member and a lateral member."

Plaintiff asserts that there is nothing in the claim language or specifications that suggests that the yarn used to form the
netting arrangement must be heavier than the thread found in the stockinette member. According to plaintiffs the term
"strand" refers to the location of the yarn only, i.e., "strand" relates solely to the netting arrangement rather than the
stockinette member.

By adding defendants' proposed language of "heavier than the yarn used to form the stockinette member," plaintiffs properly
contend defendants are limiting the claim to a preferred embodiment while ignoring the second preferred embodiment that
actually demonstrates the composition of the yarn used to form the netting arrangement and the stockinette can be the same
material, i.e., yarn of the same weight instead of heavier for the netting arrangement and lighter for the stockinette member.

The Court adopts plaintiffs' construction of the term "strand": "a yarn or yarns used in forming the lateral and longitudinal
structures of the netting arrangement."

"Strap Opening"

Finally, while the parties also dispute this term, the patent is straightforward. A strap opening is an opening for the arm of a
user, formed by a section of strap as it extends from one securing point to another. There are two strap openings as part of
the subject invention, one formed by the first strap section, and one formed by the second strap section.

Claim Construction

Chesapeake, as cross-appellant, contends that the district court erred in its construction of the claims of the '951 patent.
Claim construction is a matter of law which this court reviews without deference. Cybor Corp. v. FAS Techs., Inc., 138 F.3d
1448, 1456, 46 U.S.P.Q.2d (BNA) 1169, 1174 (Fed. Cir. 1998) (en bane). In its Markman ruling, the district court correctly
interpreted "strata in the earth" and "said strata" to mean identifiable and distinguishable layers of material (e.g., rock)
beneath the surface of the earth. Union Pac. Res. Co. v. Chesapeake, 4:96-CV-726-Y, slip op. at 7 (N.D. Tex. Nov. 30, 1998, Order Granting In Part Defendants' Motion for Claim Interpretation Based on Intrinsic Evidence) (Markman Motion). The court also correctly interpreted "information characterizes said strata," "characterizing information of said strata," and "characterizing information" to mean data produced by logging methods conventional in the industry. These conventional methods permit identification of distinguishing characteristics between layers of rock beneath the surface of the earth. Markman Motion at 7-8. In particular, these phrases can refer to information such as: (1) an X offset (east/west coordinate); (2) a Y offset (north/south coordinate); (3) a true vertical depth (TVD) or Z offset; and (4) a value from a gamma ray log. '951 patent, col. 2, ll. 5-8; col. 5, ll. 47-56.

GO BACK

3817

1. "streamer positioning device(s)"; "the positioning device"

This phrase is used throughout the Bittleston Patents. WG seeks to construe the term as "a device that controls the position of a streamer as it is towed (e.g. a "bird")." Ion seeks to construe the term as "device(s) used to steer/position the streamer both vertically and horizontally." WG argues that Ion's construction improperly attempts to limit the scope of the terms according to the preferred embodiments, and that it would render meaningless certain language within the patent claims. Ion responds that the inventor's use of the term "the present control system" when describing this invention in the specification necessarily limits the claimed invention according to the provided description.

Turning first to the claims themselves, claim 1 of the '017 Patent teaches a method for controlling the positions of marine seismic streamers with "each streamer positioning device having a wing and wing motor for changing the orientation of the wing so as to steer the streamer positioning device laterally." ('017 Patent, Pl. Br. Ex. 1, Doc. No. 61, col. 10 ll. 37-40.) This claim language, therefore, demonstrates that each positioning device should have a wing motor such that it is capable of steering a streamer horizontally. The Court agrees with Ion in this respect.

Turning then to the invention specification, it also states that "each streamer positioning device has a wing and a wing motor for changing the orientation of the wing so as to steer the streamer positioning device laterally." ('017 Patent, col. 2 ll. 51-54.) Therefore, Ion is correct that both the claim language as well as the specification support its argument that each streamer positioning device must be capable of steering horizontally.

However, nothing in either the claim language or the specification requires that each positioning device be must be capable of controlling the vertical position of the streamer. While it is true that, as Ion suggests, the description of the inventive system as a whole provided in the specification makes clear that vertical control of the streamers is possible, this speaks only to the fact that at least one of the streamer positioning devices on each streamer would necessarily have to be responsible for vertical positioning. However, this does not mean that the each and every positioning device must be capable of vertical steering. Indeed, claim 1 of the '967 Patent specifically teaches that each streamer must have a "plurality of streamer positioning devices," making it possible under the claim terms that not every streamer positioning devices actually controls vertical positioning, although such positioning is possible as to each streamer. ('967 Patent, Pl. Br. Ex. 2, Doc. No. 61, col. 11 ll. 16-19.) Moreover, the specification makes clear that it is only a preferred embodiment of the invention that each streamer positioning device is both laterally and horizontally steerable, stating that "[p]referably, the birds are both horizontally and laterally steerable." ('017 Patent, col. 3 ll. 29-30). See Halliburton Energy Services Inc. v. M-I LLC, 514 F.3d 1244, 1251 (Fed. Cir. 2008) (noting that the use of the word "preferably" in a specification indicates that the description is only a preferred embodiment); DSW, Inc v. Shoe Pavilion, Inc., 537 F.3d 1342, 1348 (Fed. Cir. 2008) (noting that it is well-settled that claims are not to be confined to a preferred embodiment). Therefore, the Court cannot accept Ion's argument that the claim language or the specification require that this claim term be construed so as to require that each streamer positioning device be capable of vertical steering.

Furthermore, even if the Court were to accept that each and every streamer positioning device must be capable of lateral and vertical steering, the Court notes that Ion's construction limits the claim term even further, so that each streamer positioning must be actually used for both kinds of steering. This distinction is an important one, and warrants reiteration. Not only does Ion seek to construe the term "streamer positioning device" so that each device is capable of vertical and horizontal steering, but Ion's construction would also require that each streamer positioning device in fact be used for both kinds of positioning. There is certainly nothing in the specification or in the claim language which requires that the term "streamer
positioning device" be so narrowly construed. Indeed, the specification discloses examples of birds that are used for vertical steering, lateral steering, and both. (See Pl. Br., Doc. No. 61, at 11 (citing to the '017 Patent).)

Finally, as WG points out, the patent claims themselves consistently reference whether the positioning devices within the scope of each claim are being used for horizontal steering, vertical steering, or both. Thus, to construe the term "streamer positioning device" with reference to its horizontal or vertical capabilities would, as WG argues, render certain language provided within the claims redundant. An example of this provided by WG is claim 1 of the '017 patent, which recites a "streamer positioning device having a wing . . . to steer the streamer device laterally." (017 Patent, col. 10 ll. 37-40.) Thus, throughout these patents, the claims consistently "call out," whether lateral or vertical steering is envisioned within the scope of the claim. As such, it is not necessary to construe the term "streamer positioning device" with reference to the way it is used for purposes of steering, as this is often what is described within the claim itself. Accordingly, the Court must reject Ion's proposed construction. WG's proposed construction, by contrast, reflects the ordinary meaning of the term "streamer positioning device." This construction applies the "widely accepted meaning of commonly understood words." Phillips, 415 F.3d at 1314. The Court will therefore construe the term "streamer positioning device" as "a device that controls the position of a streamer as it is towed (e.g. a 'bird')."

1. "active streamer positioning device"

This term is used throughout the Zajac Patent. WG seeks to construe this term as "a device for controlling the horizontal and/or vertical position of a seismic streamer." Ion seeks to construe this term as "device used to control the vertical and horizontal positioning of a streamer."

The Court first notes that the Zajac Patent, as compared to the Bittleston Patents, makes more explicit the requirement that each active streamer positioning device ("ASPD") should be capable of horizontal and vertical positioning of the streamers. Claim 1 of the '038 Patent states that "the master controller" issues positioning commands to each ASPD to adjust a horizontal and vertical position of a first streamer relative to a second streamer. ('038 Patent, Pl. Br. Ex. 5, col. 11 ll. 23-26.) As Ion points out, because the controller issues horizontal and vertical positioning commands, such commands would be futile unless each ASPD was capable of receiving both horizontal and vertical positioning signals. Claim 19 of this Patent goes on to describe a seismic streamer array positioning system wherein an ASPD "is attached to each seismic streamer for vertically and horizontally positioning each seismic streamer." ('038 Patent, col. 12 ll. 63-65.) Thus, this claim also indicates that an ASPD is attached to a streamer for both vertically and horizontally positioning the streamer. In addition, the specification uses "present invention" language and states that "one or more ASPD is employed on each seismic array" ('038 Patent, col. 3 ll. 1-6.) As Ion argues, because the invention only requires that at least one positioning device be located on each streamer, this device would, in order to effectuate the patented technology, necessarily have to control both vertical and horizontal steering. Therefore, unlike with the Bittleston Patents, the Court can conclude that the ASPD described in the Zajac Patent must be capable of both vertical and horizontal positioning.

Nonetheless, that each ASPD must be capable of both types of steering need not be equated with use of each of the devices for vertical and horizontal positioning. Indeed, Ion appears to admit this when it states that "Ion does not dispute that an ASPD can be operated in only a horizontal positioning mode." (Def. Resp. Br., Doc. No 73, at 15.) The Court's construction of the disputed term must, therefore, reflect this distinction between capability and use, because neither the patent claims nor the specification disavow the possibility that the ASPDs might be used for either vertical or horizontal positioning, although they are capable of both. As WG argued during the hearing, the summary of the invention says only that the streamer must be controlled both vertically and horizontally, but not that every single ASPD must perform both functions. While WG's construction reflects that the ASPD may be used for either vertical or horizontal positioning, however, the construction that it offers does not make clear that the ASPD must be capable of both types of the positioning. As such, this Court will not adopt the construction offered by either party, and instead construes this claim term as "a device capable of controlling the vertical and horizontal position of the seismic streamer."
8. "streamer separation mode"

This phrase is used in claim 8 of the '017 and '607 Patents, claim 9 of the '967 Patent, and claims 1, 13, 18, and 30 of the '520 Patent. WG seeks to construe this term as "a control mode that attempts to set and maintain the spacing between adjacent streamers." Ion seeks to construe this term as a "mode wherein the global control system attempts to maximize the distance between adjacent streamers." The primary dispute between the parties, therefore, is whether this control mode should be construed so as to require that the global control system act to maximize the distance between streamers.

Ion once again points out that its construction of the term tracks the language used in the patent specification, or the description of the "inventive system." Once again, however, the Court declines to use the specification language to limit the scope of this term. As to the necessity of the global control system, as stated above, the Court must recognize that certain claims within the '520 Patent describe the implementation of the streamer separation mode with no reference to a global control system. Therefore, although the specification makes clear that use of the global control system to implement this mode is a preferred embodiment of the invention, the Court declines to construe this term such that it requires a global control system. Innova/Pure Water Inc., 381 F.3d at 1117 (stating that "[p]articular embodiments appearing in the written description will not be used to limit claim language that has a broader effect").

Furthermore, as WG points out, claim 8 of the '017 Patent describes the streamer separation mode as one where the global control system attempts to direct the streamer positioning device "to maintain a minimum separation between adjacent streamers." ('017 Patent, col. 11 ll. 12-16.) Construing the streamer separation mode as an attempt to maximize the distance between the streamers would, therefore, directly conflict with this claim language, which calls for only a minimum separation distance between adjacent streamers. In addition, claim 14 of the '520 Patent, which is dependent on claim 13, specifically cites a limitation wherein the control system is "attempting to maximize the distance between adjacent streamers." ('520 Patent, col. 11 ll. 57-59.) Because this is a dependent claim, it is presumably narrower than the preceding independent claim, which describes the streamer separation mode as one where "the control system is attempting to minimize the risk of entanglement of the streamers." ('520 Patent, col. 11 ll. 54-56.) Accordingly, the Court declines to construe this term as requiring either a global control system or distance maximization. Instead, the Court will adopt WG's construction, and holds that streamer separation mode should be construed as "a control mode that attempts to set and maintain the spacing between adjacent streamers."

1. "Stress-induced martensite"

The parties agree that "stress-induced martensite," is martensite that is formed from austenite by the application of stress. The crux of the dispute is whether martensite must form by the application of stress alone or whether temperature also is a factor in the process. Gore urges the former, and the Court shall refer to Gore's proposed inclusion of this requirement as the "isothermal limitation."

Medtronic correctly notes that the disputed claim term does not contain an "isothermal limitation." When the Court looks at all the claims in which the term is used, it appears that when Jervis included an "isothermal" limitation, he either did so expressly or did so in connection with the reversion of the stress-induced martensite to austenite. (See, e.g., '957 Patent, 11:26-36, 12:14-25; '546 Patent, 11:62-66, 13:10-13; '141 Patent, 11:12-20) 3

3 The '546 and '141 Patents are attached as Exhibits 2 and 3, respectively, to the Bianrosa Declaration.
The Court also considers the claim language in light of the specification of which it is a part. See Markman, 52 F.3d at 979. In the Background of the Invention section of the specification, Jervis states:

Many [SMAs] are known to display stress-induced martensite (SIM). When an SMA sample exhibiting stress-induced martensite is stressed at a temperature above M[s] (so that the austenitic state is initially stable), but below M[d] (the maximum temperature at which martensite formation can occur even under stress) it first deforms elastically and then, at a critical stress, begins to transform by the formation of stress-induced martensite. Depending on whether the temperature is above or below A[s], the behavior when the deforming stress is released differs. If the temperature is below A[s], the stress-induced martensite is stable; but if the temperature is above A[s], the martensite is unstable and transforms back to austenite, with the sample returning (or attempting to return) to its original shape. This effect is seen in almost all alloys which exhibit a thermoelastic martensitic transformation, along with the shape memory effect. However, the extent of the temperature range over which SIM is seen and the stress and strain ranges for the effect vary greatly with the alloy.

('957 Patent. 1:50-2:2.) This portion of the specification supports Medtronic's assertion that temperature will be a factor in the formation of stress-induced martensite. Similarly, there are references in the specification that suggests the "isothermal" limitation referred to the reversion process. (See, e.g., id., 4:1-2 ("the alloy reverts to austenite without requiring a change in temperature").)

Gore contends that the prosecution history of the Jervis Patents demonstrates that Jervis "repeatedly disclaimed use of temperature change as part of his invention." (Opp. Br. at 7:13-14.) For example, Gore refers to a Response to Office Action, dated January 27, 1996, in which Jervis states, "[s]trictly speaking the Applicant is taking advantage of the shape memory effect [t]he difference is that the material transforms isothermally instead of over a temperature range." (Bianrosa Decl., Ex. 8 at p. 3.) 4 The paragraph immediately preceding this statement demonstrates that Jervis was responding to the Examiner's concern that "while Applicant is claiming a device and method whereby a shape memory alloy is utilized it appears that the shape memory effect is not utilized." It also directed to the Examiner's request for clarification of the invention. (Id.) Jervis responds by noting that he was, in fact, taking advantage of the shape memory effect, albeit through the use of an alloy that displays stress-induced martensite at body-temperatures. (Id. at pp. 3-6.)

4 This response was submitted to the USPTO during the prosecution of an application, subsequently abandoned, that was a predecessor to the application that issued as the '957 Patent.

Similarly, when Jervis distinguished the Shreck reference, he noted that martensite can be formed by cooling or by the application of stress. However, the discussion does not suggest that temperature plays no factor in the formation of stress-induced martensite. Other references cited actually support Plaintiff's position that the "isothermal" reference pertains to the reversion of martensite to austenite, rather than to its formation from austenite in the first instance. (See, e.g., Bianrosa Decl., Ex. 12 at p. 4.) Having considered the references in the prosecution history upon which Gore relies, the Court finds that they do not support a conclusion that, in order to distinguish his invention over prior art, Jervis limited the term "stress-induced martensite" to martensite that is formed solely by the application of stress.

Accordingly, the Court construes the term "stress-induced martensite" to mean: "martensite that forms from austenite due to stress."

I. Ms Temperature at Zero Stress

Medtronic argues that the patents-in-suit teach that Ms must be determined at zero stress, because with the addition of stress Ms shifts and is no longer a constant temperature. BSC contends that this is too broad a reading as it includes austenite that is stressed, raising the temperature of Ms, and then cooled to below the new temperature. Therefore, according to BSC, the martensite that formed was thermally, not stress, induced. BSC would have the Court read into the term stress-induced...
martensite the words "without cooling" or, as later argued by BSC, isothermal.

Jervis taught in the '957 patent that "when an SMA sample exhibiting stress-induced martensite is stressed at a temperature above Ms (so that the austenitic state is initially stable), but below Md . . . it first deforms elastically and then at a critical stress, begins to transform by the formation of stress-induced martensite." (the '957 patent, col. 1, Ins. 51-58.) An SMA's Ms temperature is constant only at zero stress because with the application of stress the Ms temperature rises. Thus, in order for a person skilled in the art to know what the Ms temperature is, if it is not at zero stress, the patent would have to disclose the amount of stress that is being applied to the SMA—which it does not. Moreover, in the '378 patent, Jervis lists a number of alloys and gives one Ms temperature for each alloy, without addressing the issue of stress. Accordingly, the Court concludes that the Ms temperature referred to in the patents-in-suit represents the temperature at which martensite will begin to form at zero stress.

II. Without Cooling

BSC relies on the following language from the patents themselves and their file histories in support of its reading "without cooling" into the term stress-induced martensite:

If a [stress-induced martensite] pseudoelastic wire is used to form the coil, which is then isothermally deformed by loading into a catheter, then the need for temperature control is avoided. The wire remains straight when in the catheter, but re-forms the coil spontaneously when it is extruded from the catheter. Accurate placement is thus readily obtainable, since there is no urgency as might be required with a conventional shape memory effect element.

(Robbennolt Aff. Ex. 1 (the '957 patent, col. 9, Ins. 39-47) (emphasis added).) "If an [stress-induced martensite] pseudoelastic wire is used, it can exert a relatively constant force . . . . The load may be applied mechanically, and is thus more readily established, and no precise temperature control of the alloy is needed as would be required for the shape memory effect." (II at col. 9, Ins. 10-17 (emphasis added).) Both of these statements are taken from examples of uses for stress-induced martensite under the preferred embodiment section of the '957 patent. It is unclear how the use of the word isothermal in one of eight examples limits the definition of stress-induced martensite. Moreover, the statement "no precise temperature control of the alloy is needed" does not lead to a finding that temperature control of an SMA prevents any resulting martensite from being termed stress-induced.

In addition, Jervis argued to the PTO, in order to overcome prior art, that "strictly speaking, the Applicant is taking advantage of the shape memory effect since there is a - transformation between austenite and martensite when the material acts pseudoelastically. The difference is that the material transforms isothermally instead of over a temperature range" (Lehmann Aff. Ex. E (Jervis '852 Appl. filed October 14, 1983; Jan. 13, 1986 Response to Office Action, p. 3)(emphasis added).) 3 Again, the Court is not persuaded that an isolated statement made to the PTO distinguishing stress-induced martensite from martensite that forms over a temperature range, that is cooling below Ms, limits stress induced martensite to martensite created without any temperature variation.

-------- Footnotes --------

3 The '957 patent is a continuation of co-pending commonly assigned application No. 047,824, filed May 8, 1987, which is a continuation of application No. 865,703, filed May 21, 1986, now United States patent No. 4,665,906, which is a continuation of application serial No. 541,852, filed October 14, 1983. (Lehmann Aff Ex. A, the '957 patent file history.)

-------- End Footnotes --------

BSC also claims that Jervis should be bound by the term "without cooling" because this is how he was able to distinguish his patents from the prior art. In support of this argument BSC quotes portions of the following language from the prosecution history of the '378 patent:

By way of background, there are two techniques available for transforming an appropriate alloy into the martensitic state. The first technique . . . is cooling the material so that martensite forms at Ms under no stress. By the second technique . . . the same material, martensite can form above Ms if stress is applied, thereby forming stress-induced martensite. The present invention is directed to use of the unique properties of stress-induced martensite, not martensite formed by cooling.
The underlined language was omitted by BSC. BSC argues that the last sentence supports its addition of "without cooling" to the definition of stress-induced martensite. The Court disagrees. Instead of using the terms stress-induced martensite and thermal-induced martensite, Jervis referred to the two techniques as one that required cooling below Ms at zero stress and one that will form above the Ms temperature at zero stress if stress is applied. Accordingly, he distinguishes the two techniques by calling thermal-induced martensite, the first technique, martensite formed by cooling. This does not translate into a finding that stress-induced martensite must form without cooling.

The narrowing of the term stress-induced martensite by BSC is not supported by the plain meaning of the claim language, and the Court will not read extraneous terms from the prosecution history or the claim specification into the claim under the guise of term interpretation. See Intervet Am., Inc. v. Kee-Vet Labs., Inc., 887 F.2d 1050, 1053 (Fed. Cir. 1989) ("This court has consistently adhered to the proposition that courts cannot alter what the patentee has chosen to claim as his invention, that limitations appearing in the specification will not be read into claims, and that interpreting what is meant by a word in a claim 'is not to be confused with adding an extraneous limitation appearing in the specification, which is improper.") (quoting E.I. duPont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988)).

Medtronic's definition of stress-induced martensite represents the plain meaning of that term. Accordingly, the Court construes the term stress-induced martensite to mean: Martensite that forms from austenite due to the presence of stress, applied while the alloy is above its Ms temperature, where Ms is determined at zero stress.

C. Claims 1 & 9: "A roll of stretched plastic film for wrapping a pallet load"

Pliant asks me to construe the "roll of stretched plastic film" as a roll of "previously stretched (i.e., mechanically elongated) plastic film." Defendants object to the use of the term "previously," arguing that the inventor disclaimed the term during the patent's prosecution. The prosecution history reveals that the inventor's proposed claims were rejected several times before approval. Until the final set of claims was proposed in 1995, the inventor consistently used the term "prestretched." The inventor used the term to convey the idea that the stretching occurred before the plastic was rolled. In October 1995, the patent examiner proposed a new claim to "correct[] ambiguities in the claim." The proposed claim substituted the word "stretched" for "prestretched." The inventor adopted this language, uniformly substituting "stretched" for "prestretched" when proposing his final amendments. Nonetheless, the revised claim continues to teach that the film is first stretched, then rolled. Those amendments were approved by the patent examiner.

On the basis of this prosecution history, Defendants ask me to find that the patentee explicitly disclaimed the concept of prestretching.

The purpose of consulting the prosecution history in construing a claim is to "exclude any interpretation that was disclaimed during prosecution." Accordingly, "where the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender." Such a use of the prosecution history ensures that claims are not construed one way in order to obtain their allowance and in a different way against accused infringers.

Chimie v. PPG Indus. Inc., 402 F.3d 1371, 1384 (Fed. Cir. 2005) (citations omitted). The substitution of "stretched" for "prestretched" in response to the patent examiner's concerns about ambiguity was not a clear disavowal of the concept that the film is stretched before it is rolled. However, Pliant's proposed insertion of the word "previously" into its proposed construction of the claim is unnecessary. (See '393 Patent, Claims 1 and 9) ("the stretched film then being rolled"). If anything, it adds an element of ambiguity into a claim amended to remove unnecessary confusion. Therefore, I construe the term "a roll of stretched plastic film" to mean "a roll of stretched (i.e., mechanically elongated) plastic film."
At the threshold, the parties disagree on the proper function performed by the "means for causing" in claims 1 and 3 of the '880 patent. According to the text of claim 1, on which claim 3 is dependent, the "means" causes "at least one laser beam to strike the periphery of the energy zone for visibly outlining said entire energy zone." '880 patent, col. 9, ll. 39-41 (emphases added). The district court construed the phrase "strike the periphery . . . for visibly outlining" in the claims' function as encompassing the "projection of the laser light toward the surface, but does not encompass light striking the center or interior portion of the energy zone." In reaching that interpretation, the trial court reasoned that the language of claims 1 and 3 requires the laser beam to only strike the periphery of the energy zone. To buttress that decision, the district court indicated that permitting the laser beam to strike the center of the energy zone would be contrary to the claim's purpose of visibly outlining the energy zone and contradict an express element of the claim. However, neither the reasons provided by the district court nor our plenary review of the intrinsic evidence support that claim interpretation.

"When construing the functional statement in a means-plus-function limitation, we must take great care not to impermissibly limit the function by adopting a function different from that explicitly recited in the claim." Generation II Orthotics, Inc. v. Med. Tech., Inc., 2001 U.S. App. LEXIS 18420, 263 F.3d 1356, 1364-65, 59 USPQ2d 1919, 1926 (Fed. Cir. 2001). Despite that admonition, the trial court's ruling incorporated into the claim language a novel negative limitation, precluding the laser beam affected by the "means for causing" from striking the center or the interior of the energy zone. As construed by the district court, claims 1 and 3 now encompass a "means for causing said at least one laser beam to strike the periphery of the energy zone, but not strike the center or interior portion of the energy zone, for visibly outlining said entire energy zone."

This additional negative limitation finds no anchor in the explicit claim language. The express text of the claims does not prohibit the laser beam from striking inside the energy zone. The claims' wording only calls for the laser beam to "strike the periphery of the energy zone for visibly outlining said entire energy zone." '880 patent, col. 9, ll. 39-41. The phrase added by the district court finds no support in the text of the claims.

Nor is that negative limitation inherent in the term "periphery," as believed by the district court and argued by Raytek. The term's ordinary and customary meaning as discernible from dictionary evidence, see Schumer v. Lab. Computer Sys., Inc., 308 F.3d 1304, 1311, 64 USPQ2d 1832, 1838 (Fed. Cir. 2002) ("The proper approach is to construe the claim language using standard dictionary definitions, because here, the claims have no specialized meaning.")., is "the perimeter of a circle, ellipse, or other closed curvilinear figure." Webster's Third New Int'l Dictionary 1681 (1993). That definition does not necessitate the addition of a negative limitation, since nothing in the term's denotation precludes the laser beam from striking inside the energy zone's perimeter. The plain words of the claims merely require that the laser beam strike the periphery of that zone.

In the same vein, we do not agree with the trial court that directing light inside the energy zone would contradict the claim's stated purpose of "visibly outlining said entire energy zone." The inherent contradiction identified by the district court exists only because it assumed that a laser beam directed inside the energy zone cannot at the same time outline that zone. That assumption, in turn, supposes two facts: (1) the claimed invention only has one laser beam, and (2) the sole laser beam is incapable of outlining while striking the inside of the energy zone at the same moment. The plain words of the claims belie the first supposition, since the claims permissively call for "at least one laser beam." '880 patent, col. 9, l. 39 (emphasis added). The phrase "at least one" indicates that the "means for causing" does not necessarily act on only one laser beam. See Rhine v. Casio, Inc., 183 F.3d 1342, 1345, 51 USPQ2d 1377, 1379 (Fed. Cir. 1999) ("Use of the phrase 'at least one' means that there could be only one or more than one."). The second supposition is equally flawed, because the claims only require that the laser beam strike the periphery to outline the energy zone. In other words, striking the inside of the energy zone is not a requirement of the plain claim language, avoiding the necessity of the laser beam being both outside and inside the energy zone at the same time. Consequently, with both suppositions put to rest, the assumption made by the district court can no longer stand, exposing the alleged contradiction as a mere illusion.

Beyond the words of the claim, neither the district court nor Raytek has identified any express disclaimer or independent lexicography in the written description that would justify adding that negative limitation. See CCS Fitness, Inc. v.
Brunswick Corp., 288 F.3d 1359, 1366-67, 62 USPQ2d 1658, 1662-63 (Fed. Cir. 2002). Our independent review of the patent document, see Bell Atl. Network Servs., Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1266, 59 USPQ2d 1865, 1869 (Fed. Cir. 2001), reveals no express intent to confer on the claim language the novel meaning imparted by this negative limitation. Accordingly, we must conclude that there is no basis in the patent specification for adding the negative limitation.

17. Strip

The next term for construction is "strip" in all claims. 20 The Plaintiffs maintain that strip means "a relatively long narrow piece of something." (Pls.' Open Br. 36.) Pergo states that "strip" means "a component integrated with the floor panel which after joining, is flat and situated either flush with or slightly below the underside of the panel." (Unilin's Open. Br. 48-49.)

20 Pergo has requested construction of the term "strip" in a more limited group of claims. (See Unilin's Open. Br. 48.) One of the claims for which a construction of strip is requested is claim 1 of the '579 patent.

Claim 1 of the '579 patent states:

A mechanical locking system for locking a first edge of a first panel to a second edge of an identical second panel that are arranged on a subfloor, the mechanical locking system comprising: means on the first edge and the second edge for forming a first mechanical connection locking the first and second edges to each other in a first direction at right angles to a principal plane of the panels; a locking device arranged on an underside of the first and the second edges, the locking device forming a second mechanical connection locking the first and the second edges to each other in a second direction parallel to the principal plane and at right angles to the edges; the locking device including a locking groove which extends parallel to and spaced from the second edge, the locking groove being open at the underside of the second edge and including an internal surface; the locking device further including a strip extending from the first edge, the strip extending throughout substantially an entire length of the first edge and being provided with a locking element projecting from the strip; the strip, the locking element, and the locking groove being configured such that when the second edge is pressed against an upper part of the first edge and is then angled down against the subfloor, the locking element can enter the locking groove; the locking element has a locking surface which faces the first edge and is configured so that it can contact the internal surface of the locking groove when the first and second edges are joined together to prevent substantial separation of the joined first and second edges; and the locking element further including an outer portion which is most distant to the joined edges and is not in contact with the locking groove when the first and second edges are joined together. ('579 patent, 10:35-67; 11:1-4.) (Emphasis added).

The starting place for construction of a claim term is the claims. The Court does not interpret claim terms in a vacuum, devoid of the context of the claim as a whole. See Hockerson-Halberstadt, Inc. v. Converse Inc., 183 F.3d 1369, 1374 (Fed. Cir. 1999) ("proper claim construction . . . demands interpretation of the entire claim in context, not a single element in isolation."); ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1088 (Fed. Cir. 2003) ("While certain terms may be at the center of the claim construction debate, the context of the surrounding words of the claim also must be considered.")

Review of claim 1 of the '579 patent indicates that "strip" is used in a variety of contexts. The Plaintiffs' simple broad definition fits into different contexts. However, the inclusion of the phrase "of something" does not add to the definition. "Piece" suggests that the strip is tangible, see Webster's II New Riverside University Dictionary 890 ("a thing regarded as a unit or element of a larger quantity or class"), as does "of something." So, the Court has omitted "of something" from its definition of strip. Pergo's proposed definition adds an unwarranted temporal limitation on the term by incorporating the position of the strip after joining. The Court defines "strip" as a "relatively long narrow piece."
B. Analysis

The first disputed term is "strips of adhesive." It is undisputed that the accused form uses adhesive. The parties dispute what constitutes a "strip" of adhesive.

A "strip" is "a narrow piece of about even width." Webster's Third New International Dictionary 2264 (1993) ("Webster's"). This definition shall serve as the default because nothing in the specification suggests that the patentee chose to be his own lexicographer. See Multiform Desiccants, Inc. v. Medzam Ltd., 133 F.3d 1473, 1477 (Fed. Cir. 1998). The prosecution history shows that the applicant originally used the word "strips" throughout the specification interchangeably with "strips of adhesive" or "adhesive strips." (D.I. 138, Ex. D at D18-D26) The examiner objected to the disclosure because of the inconsistent use of that terminology (id. at D41), and the applicant amended the specification accordingly. (Id. at D53) The prosecution history does not, however, shed any light on what constitutes a "strip."

Neither party submitted extrinsic evidence to show what one of ordinary skill in the art would understand "strips of adhesive" to encompass. Since both parties' proposed definitions were drafted with an eye toward the accused product, the court will use the dictionary definition. Thus, based on the current record, a "strip of adhesive" is a narrow piece of glue of about even width. 1

1 At oral argument counsel referred the court to, inter alia, the '798 patent specification which was filed less than six months after the application for the '464 patent was filed. That patent describes "patterns of adhesive" as "discontinuous strips." ( '798 patent, col. 4, lns. 14-45) The patent also uses the terms "adhesive patterns/strips" and "longitudinal strips/patterns" in the specification. (Id., col. 5, lns. 3-5) The court also notes that the specification of another Moore mailer patent involved in a pending case before the court provides:

It will be understood that the strips of adhesive adjacent the respective side edges may be placed anywhere along the edges so long as there will be adequate adhesive to properly seal the mailer 10 when completed to satisfy users and postal authorities. In other words, the adhesive may be intermittent, such as dots. When "strip" of adhesive is used in the appended claims such intermittent coverage is included.

(U.S. Pat. No. 4,928,875, col. 2, lns. 17-24) ("the '875 patent") The application for that patent was filed more than two years before the application for the '464 patent. Absent evidence that the above explanations were understood by persons of ordinary skill in the art, the court is left with the conclusion that the inventors of the '798 and '875 patents chose to be their own lexicographers; the inventor of the '464 patent did not.

The accused device uses a series of triangle-shaped spots of glue. The court cannot conclude that the series of triangles satisfies the "first and second longitudinal strips of adhesive" element of claim 1. To be liable for literal infringement under section 35 U.S.C. § 271(a), the accused device must be shown to include every element of the claim. See Builders Concrete, Inc. v. Bremerton Concrete Prods. Co., 757 F.2d 255, 257 (Fed. Cir. 1985). Because plaintiff failed to show one element, the court cannot find that the accused form literally infringes claim 1. Moreover, since plaintiff failed to show that one claim element read on the accused form, there is no need to discuss the other disputed claim elements.
Defendant's construction: A "strip of material" does not include an object that disintegrates or dissolves in the mouth during use. A "strip of material" is a piece of material that has structural integrity separate and apart from the layer of a tooth whitening substance of composition recited in the claims, and that has the following mandatory characteristics: it is conformable to the contoured surfaces of the teeth (and, in the case of the '579 patent, is conformable without permanent deformation); it serves as a substantially water impermeable barrier during use; it has low flexural stiffness; and it is easily removable and intact after use. In addition, the term 'strip of material' is indefinite as to the shapes that fall inside or outside the scope of the claim term.

Defendant dispute the meaning of "strip of material" on two alternate theories. First, defendant argues that a "strip of material" is insolubly ambiguous because the patents do not indicate what shapes fall within and outside the scope of the term. Second, defendant contends that a strip of material cannot "dissolve" and that it must include five mandatory limitations found in the specification. I agree with plaintiff that these two positions taken by defendant appear to be in tension with each other; regardless, I conclude that the patents disclose a range of possible shapes for a "strip of material" and therefore, the term is not insolubly ambiguous. Further, I find that neither the claim language nor the specification requires that the claim be construed to include defendant's asserted limitations except the "flexural stiffness" limitation in both patents and the "substantially water impermeable limitation" in the '579 patent.

a. Indefiniteness: shape of "strip of material"

The standard for indefiniteness is high. "If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree," the claim is sufficiently clear to avoid indefiniteness. Exxon Research and Engineering Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001). A claim is indefinite only if the "claim is insolubly ambiguous, and no narrowing construction can properly be adopted." Id.

In the '240 patent, the inventors described a strip of material as "sized to cover the front surface of one or more teeth and soft tissue adjacent said front surface of the one or more teeth." '240 Pat., col. 17, Ins. 20-23. In the '579 patent, they described a strip of material as "sized to cover a front surface of a plurality of teeth." '579 Pat., col. 14, Ins. 34-36. Both patents disclose the shape of strip of material as one that could cover either one or more teeth. From this description, one knows what the general metes and bounds are and what shapes would not work, such as circles, cubes, pyramids or disks. Thus, contrary to defendant's contention, it is possible to narrow the possible universe of shapes that could be a "strip of material" claimed in both the '240 and '579 patent. It follows that a "strip of material" is not indefinite.

b. Limitations

Although plaintiff is correct that courts should be cautious about reading limitations from preferred embodiments into the claim language, a court cannot disregard the specification altogether. It is an essential tool in discerning the meaning of claim terms when there is a lack of accepted meaning in the art. Irdeto Access, Inc. v. Echostar Satellite Corp., 383 F.3d 1295, 1300 (Fed. Cir. 2004) (when no accepted meaning, "[t]he duty . . . falls on the patent applicant to provide a precise definition for the disputed term."). In this case, the parties dispute what qualities a "strip of material" must have in order to practice either the '240 or '579 patent. Most of the limitations that defendant proposes are merely qualities found in preferred embodiments or unfounded extrapolations defendant draws from the specification. The only limitations implicitly required are that the "strip of material" in the '240 and '579 patents have a "low flexural stiffness" and that the "strip of material" in the '579 patent be "substantially water impermeable."

1) limitations found in the specification: "flexural stiffness" and "substantially water impermeable"

It is clear in both the '240 and '579 patent when the inventors are discussing "preferred embodiments" in the specification. In certain instances, however, the specification describes the claim terms generally.

a) limitations in the '240 patent

The specification states that "the strip of materials 12 should have a relatively low flexural stiffness so as to enable it to drape over the contoured surfaces of the teeth with very little force being exerted. . . ." '240 Pat., col. 11, Ins. 10-13 (emphasis added). In this instance, the patent is referring to the "strip of material" generally and not merely to a preferred embodiment.
of the invention, as it clearly does in other instances. E.g., '240 Pat., col. 3, Ins. 13-18 (detailed description of preferred embodiments); col. 5, Ins. 17-18 ("Referring again to FIG. 9 and while not intending to be bound by any theory"); col. 6, Ins. 19, 41, 66 (indicating descriptions of particular embodiments). Therefore, I agree with defendant that this quality of the strip of material is not an optional but a mandatory feature. However, I do not agree with defendant that the strip of material must always be "water impermeable." Defendant identifies no language in the specification that explicitly describes the "strip of material" as being "water impermeable." Accordingly, I will not import this limitation into the term "strip of material" as used in the '240 patent.

b) limitations in the '579 patent

The specification of the '579 patent provides that "[i]n the present invention, the strip of material has a flexural stiffness of less than about 5 grams/cm . . . ". '579 Pat., col 4, 34-35. The patent also describes the importance of the "strip of material" having a "low flexural stiffness." '579 Pat., col 4, ln. 22 - col. 5, ln. 20. "When a patent thus describes the features of the "present invention" as a whole, this description limits the scope of the invention." Verizon Services Corp. v. Vonage Holdings Corp., 503 F. 3d 1295, 1308 (Fed Cir. 2007). Therefore, I agree with defendant that as in the '240 patent, this is not an optional but a mandatory feature of the '579 patent.

The specification also discloses possible materials that might compose the "strip of material" and whether it may contain multiple layers of the material. However, the specification states that "regardless of the number of layers, the strip of material is substantially water impermeable." '579 Pat., col 3, 51-52. This section also refers to the "strip of material" generally and not as a preferred embodiment. The use of the word "regardless" in this instance suggests that no matter what substance constitutes the "strip of material," it must be "substantially water impermeable." Therefore, I conclude that this feature is a mandatory feature of the '579 patent.

2) limitations not found in specification

Although the parties dispute a number of issues related to the term "strip of material," their core dispute focuses on whether plaintiff's patents disclose a strip of material that can dissolve in the user's mouth. Defendant asserts that the main difference between its whitening product and plaintiff's is that the Listerine Whitening (R) Quick Dissolving Strips dissolve in the user's mouth. Defendant believes that plaintiff's patent discloses a product that does not dissolve because the patents nowhere mention that the "strip of material" dissolves. In addition, as defendant points out in support of its non-dissolution argument, the '579 patent requires that (1) the strip of material must be removed intact from the mouth; (2) it must be conformable to the contoured surfaces of the teeth without permanent deformation; and (3) it must have structural integrity. Defendant is partially correct. It is correct in saying that the patents do not mention whether the strip of material dissolves but it does not acknowledge that the patents do not require that the strip be non-dissolving or require expressly or implicitly that the strip of material must retain any of the other limitations defendant would assign it.

With respect to the argument regarding dissolution, defendant suggests that because the strip of material "serves as a protective barrier . . . to prevent saliva from contacting the tooth whitening composition [or substance]," '240 Pat., col. 3, Ins. 27-31; '579 Pat., col. 3, Ins. 35-37, the strip cannot dissolve in the mouth. Defendant assumes that because the strip must be a protective barrier it cannot later dissolve, but it points to no language in the specification and offers no evidence or expert testimony to support its assumption that a protective barrier cannot dissolve at some point. I conclude that the requirement that the "strip" function as a "protective barrier" includes no requirement that a strip of material not dissolve.

In arguing that the "strip of material" must be removable and therefore non-dissolvable, defendant identifies a number of passages in the specification that it believes indicate that the strip of material must be removed from the mouth. One of the passages states that "the strip of material [can be] easily removed by the wearer by simply peeling off the strip of material using ones [sic] finger, fingernail or rubbing with a soft implement such as a [sic] cotton balls and swabs or gauze pads." '579 Pat., col. 4, ln. 64 - col. 5., ln. 2. A second passage states that "The delivery system is easily removable from the oral surfaces without the use of an instrument, a chemical solvent or agent or excessive friction." '579 Pat., col. 5, Ins. 2-4. Contrary to defendant's proposed construction requiring non-dissolution, the specification says nothing about the strip's being removed from the mouth or that it be removed intact; it requires only that the strip of material be removable from the oral surface, which is the user's teeth. Therefore, this proposed limitation will not be read into the '579 patent.

Defendant cites the requirement in the specification of the '579 patent that the strip of material be "easily conformable to

- 4486 -
Molten's construction expands the term itself to include a larger portion of the claim. Molten's proposed construction of "strips of seam material", or a narrow piece of material that constitutes a seam.

C. Strips of seam material

The parties dispute the meaning of the term "strips of seam material." This term is found in claim numbers 1, 3, and 5. Baden argues that "strips of seam material" should be construed as "strips of seam material." Molten suggests that "strips of seam material" should be construed as "raised seams having a raised portion which is filled with an underlying foam layer" or "a seam having an outer surface formed by thin rubber strips and an inner portion of foam attached to the strips." Molten is arguing that Baden's patent is limited to a design with strips of seam material with a raised portion that is not solid underneath, but rather, has foam underneath and within the raised portion of the seam. The Court does not agree that Baden's patent is limited in this way.

The Court agrees with Baden that the ordinary and plain meaning of the words "strips of seam material" is "strips of seam material". Stated differently, in isolation, this term means a narrow piece of material that constitutes a seam. This interpretation is supported by the claims themselves. The term is used throughout the claims. For example, in Claim 1, "each strip of seam material comprises: a raised portion positioned between spaced, outer edges of the skin panels on opposite sides of the raised portion; and flange portions extending away from opposite sides of the raised portion." And Claim 1 states "a plurality of raised seams defined by strips of a seam material, wherein the sponge layer underlies the raised seams." Claim 3 states "a plurality of raised seams defined by strips of a seam material, wherein the strips of seam material are bonded directly to the cellular sponge layer and the sponge layer underlies the strips of seam material . . . ." Claim 5 states "a plurality of raised seams defined by strips of a seam material attached to the cellular sponge layer . . . and, wherein, each strip of seam material includes a raised portion positioned between spaced, outer edges of the skin panels on opposite sides of the raised portion . . . ." In all of these contexts, 'the most straightforward meaning of "strips of seam material" is "strips of seam material", or a narrow piece of material that constitutes a seam.

Molten's construction expands the term itself to include a larger portion of the claim. Molten's proposed construction of
"strips of seam material" is really a proposed construction of "strips of a seam material, wherein the sponge layer underlies the raised seams." (Claim 1). But even considering that phrase as one term, the Court is not convinced that the term means "raised seams having a raised portion which is filled with an underlying foam layer." Molten's construction is not supported by the claim language. None of the claim language discusses the raised portion of the seam being "filled" with foam; instead, it discusses the sponge or foam layer underlying the seam strip.

Molten's construction does find support in Figure 3 of the '835 patent. That figure shows a seam with a raised portion, and within that raised portion is foam. But the claims themselves do not contain language that limits the design to that particular graphic representation. The Court will therefore not limit the claims to the graphic representation in Figure 3. See Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571 (Fed. Cir. 1988) ("Although the specification may aid the court in interpreting the meaning of disputed language in the claims, particular embodiments and examples appearing in the specification will not generally be read into the claims.").

Molten also makes arguments regarding the prosecution of the '283 patent. But the Court is not considering the '283 prosecution history because Baden has amended its complaint to eliminate its cause of action based on that patent. And even if the Court were to consider the prosecution history of the '283 patent, the Court does not agree with Molten that the '283 prosecution history limits the patent to Molten's proposed construction. The prosecution history makes clear that Baden's '835 patent is limited to a design with a sponge layer under both the exterior panels and the rubber seams. The prosecution history presented by Molten does not suggest that Baden's '835 patent is limited to seams filled with foam.

CONCLUSION

Because Baden's proposed construction of both of the disputed claim terms is supported by intrinsic evidence, the Court adopts Baden's proposed construction of "raised seams" and "strips of seam material." "Raised seams" means "a piece of material that is at a higher position than the sponge layer of the basketball." "Strips of seam material" means "strips of seam material."

Home Depot further argues that the Industriaplex device does not include a "dust collection structure for collecting sawdust," a limitation found in each claim of the '039 patent. Home Depot argues that this limitation is a "means-plus-function" limitation within the meaning of 35 U.S.C. § 112 P 6, which provides that a claim limitation "may be expressed as a means or step for performing a specified function with the recital of structure, material, or acts in support thereof." The significance of classifying this limitation as a means-plus-function limitation is that it would restrict the scope of the limitation to structures that collect sawdust by the particular means described in the patent, rather than through simply any "dust collection structure." "Literal infringement of a means-plus-function claim limitation requires that the relevant structure in the accused device perform the identical function recited in the claim and be identical or equivalent to the corresponding structure in the specification." Applied Medical Resources Corp. v. U.S. Surgical Corp., 448 F.3d 1324, 1333 (Fed. Cir. 2006).

However, claims 1 and 4 do not use the term "means." When a claim element does not use the term "means," there is a rebuttable presumption that the element is not a "means-plus-function" limitation. See TIP Systems, LLC v. Phillips & Brooks/Gladwin, Inc., 529 F.3d 1364, 1373 (Fed. Cir. 2008). The presumption "is a strong one that is not readily overcome." See Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004). The presumption is rebutted only if the claim recites sufficiently definite structure to make the function understood by one reasonably skilled in the art. See DePuy Spine, Inc. v. Medtronic Sofamor Danek, Inc., 469 F.3d 1005, 1023 (Fed. Cir. 2006); CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002).

Here, it appears that the patent recites sufficient structure corresponding to the dust-collection function to rebut the presumption. The patent specification describes the dust-collection structure as containing two ports through which sawdust exits the cutting box, and a dust-collection tray. See '039 patent 7:40-56. The ports and tray are also depicted in Figure 4 of the '039 patent. Based on these detailed descriptions, the court concludes that the patent recites sufficiently definite structure corresponding to the dust-collection function referenced in the claim that the limitation is properly considered a "means-plus-function" limitation within the meaning of 35 U.S.C. § 112 P 6.
a. "strut"

The term "strut" appears in the '682 Patent. Boston Scientific proposes that the term "strut" be construed as "a component that braces the filter." At the Markman hearing, ev3 indicated that it would be content to bring a summary judgment motion for invalidity if the Court were inclined to accept Boston's proposed construction. The Court construes "strut" as "a component that braces the filter."

b. "strut disposed in a radially asymmetric pattern"

The term "strut disposed in a radially asymmetric pattern" appears in the '682 Patent. The Court construes this phrase as "strut positioned on the guidewire in a manner that is not symmetric about the guidewire."

(6) "two sides, each having a stud, each stud including a magnetic material"

Plaintiffs define "two sides" to mean "those portions of the primary spectacle frame beginning at the point where a line drawn through the midpoints of the lenses and lens rims (if supplied) would intersect the top and bottom of the primary spectacle frame, and terminating at the pivot point where the legs are attached to the studs." JS, Exh. A at 13. Further, Plaintiffs construe "stud" to mean "those portions of the primary spectacle frame which include a magnetic material and extend outwardly and rearwardly of the lenses or lens rims (if provided). The studs pivotally connect to the legs or temple pieces," Id. at 14. Additionally, Plaintiffs contend that the phrase "including a magnetic material" means "(respecting the studs), . . . that at least a portion or segment of each stud is a magnetically attractive substance, such as, for example, a magnet. The magnetic material may be embedded in or secured to the remaining portions of each stud." JS, Exh. C at 108.
In this case, the terms in question are described in the specification as follows: "an eyeglass combination . . . comprises a primary frame 10 for supporting primary lenses 90 and including a bridge 11 formed in the middle and including two studs 12 formed in the side portions. The bridge 11 and the studs 12 each includes a magnet 14 disposed laterally. . . ." Koo Decl, Exh. C at 20, Col. 2, 11. 41-46. Based on the specification and the drawings, the Court construes the phrase "two sides" as those portions of the primary spectacle frame extending outward and rearward from the outer edges of the primary frame. The Court construes "stud" to mean those portions of the two sides of each primary spectacle frame which include a magnetic material and project outwardly and rearwardly of the lenses or lens rims (if provided). See also Webster's, Nicodema Decl., Exh. 5 at 154, defining "stud" as "[a] small knob, nail head, or rivet fixed in and slightly projecting from a surface." As already discussed, the Court construes magnetic material to be a permanent magnet or ferromagnetic material.

Defendant's request that the Court construe studs as "a structure projecting from the undersurface of the plate at the side edge for contact between the plate and bone, such that the area of this contact is reduced to the minimum practicable, and in any case not more than 5% of the total area of the lower surface of the plate". (Def. Mem. at 14). DePuy argues that there is no evidence establishing that any of its Accused Products contain such a limitation or a substantial equivalent thereof, so that it is entitled to summary judgment. Synthes, on the other hand, argues that "studs" means the portion of the lower surface of the plate which provide the reduced contact areas after the plate is screwed down. The term has no requirement that the stud be pointed or that it provide the minimal practicable area of contact with the bone.

Once again, the Court must first look to the claims of the 36 Patent. Studs are mentioned in Claim 1 as the open sections with the concave lower surface of the plate which provide for contact with the bone. The Plaintiff summarizes this description of studs as being downwardly-descending portions of the lower surface of the plate which provide the bone contact areas when in use. Claim 5, dependent on Claim 1, adds the additional limitation of the contact elements (studs) being less than 5% of the lower surface of the plates. A term from an independent claim can not be read differently than that term is read in a dependent claim, unless the dependent term also includes further limitations. In this instance, it would be illogical for Synthes to add this further limitation to the definition of studs in Claim 5 if the term already included a 5% or "minimum practicable" limitation (as defined in Claim 1).

The prosecution history also supports Synthes' interpretation of Studs. The patent examiner rejected earlier versions of Synthes' claims based on the Kummer patent. The examiner considered what Kummer calls 'washers and spacers' to be resorbable studs. These "studs" have large, flat areas of contact with the bone, and certainly not the "minimum practicable" area of contact. It seems probable, then, that the examiner understood studs to be a broader term than does DePuy. Therefore, because the claims of the 36 Patent and its prosecution history favor an interpretation more consistent with that offered by Synthes, studs will be construed as meaning projections that do not mandatorily have the minimum practicable or less than 5% limitation.

Additionally, claim 1(e) requires a "stuffer means." CTC contends that stuffing only means "feeding," and that a machine which uses a loading paddle and scraper blade where the loading paddle raises the dough above the horizontal axis of rotation and drops the dough into the chamber, as does Popeil's pasta maker, still infringes the '575 patent because there is no language in claim 1(e) that limits dough from falling into the entry zone of the extruding chamber by gravity. Because claim 1 is expressed as a series of means plus function limitations, we are statutorily required to look to the specification to understand the structure claimed. 35 U.S.C. § 112, P 6. The specification in referring to "stuffer means" speaks in terms of the "stuffing element" "uniformly packing" the mixed dough "to facilitate uniform entry of the packed dough into the extruding chamber without undesirable air pockets or lumpy accumulations of dough." Given the explicit references in the specification to "packing," "packed dough," and dough without undesirable air pockets or lumps, further indicating that the invention "packs" the dough, we cannot conclude that the term "stuffer means" merely teaches a means for feeding dough.
Rather, we conclude that "stuff" in "stuffer means" has its ordinary meaning of "packing" or stuffing the dough through compression. Appropriate structures were also shown in the specification to perform the dough packing or compression.

3835
7. Claim 8 - Stylus

The term "stylus" in Claim 8 refers to an object generally shaped like a pencil with a tip that is narrower than the body. (Tr. 72).

3836
9. "sub-area of an area" and "at least two substrate alignment marks located on the substrate outside said area"

Both of these claim terms permit straightforward construction. In important part, claim 1 discusses the presence of "at least two substrate alignment marks located on the substrate outside said area." '832 Patent at 32:60-61 (emphasis added). That is, claim 1 expressly contemplates a region "on the substrate" "outside" of and distinct from the "area." Were "area" to include the entire substrate (as ASML contends), claim 1's language would be self-contradictory and self-defeating; for "at least two substrate alignment marks" to be located "on the substrate" but "outside said area" demands that the "substrate" and the "area" be less than fully coextensive. The parties agree that a "sub-area" is a portion of a substrate on which a mask pattern is exposed, and consistent with this logical and linguistic truism, the court construes "sub-area of an area" to mean "a distinct portion of a larger portion of a substrate, which is to be imaged with a pattern."

For like reasons, the court construes "at least two substrate alignment marks located on the substrate outside said area" to mean "two or more 'substrate alignment marks' positioned on a substrate outside the substrate portion on which a pattern is to be exposed." Specification language supports this conception of "area" and "sub-area," see id. at 2:20-25 (placing the marks "outside the substrate area which must be repetitively illuminated with the mask pattern"), as do relevant figures. Id. at fig. 1.

3837

Snap Edge's second argument concerns the term "substantial" as used in Claim 144 to describe the "horizontal forces" experienced at the lateral edges of the "paving surface means." According to Claim 144, these forces are initially received by the "edge restraint means" and subsequently transferred by the "force converting means" and the "anchoring means" to the base surface. 7 It is undisputed that the term "substantial" is only used in Claim 144 and its dependent Claim 155.

7 Footnotes

7 Claim 144 provides in relevant part:

A paving installation, comprising: (i) paving surface means for accommodating traffic which is [sic] use experiences substantial horizontal forces at its lateral edges and which is located on top of a substantially level base surface, and (ii) edge restraint means for receiving said horizontal forces and maintaining the paving means in position, said edge restraint means being at least partially disposed below ground level and including:

* * *

(c) force converting means operatively arranged between the upright member and the extension member for transferring the substantial horizontal forces imparted to the first surface of the upright member via the paving surface means to the base surface, said edge restraint means including anchoring means engaged into the base surface.
Snap Edge suggests that, because "substantial" is nowhere defined in the '550 Reissue Patent or the file wrapper and because its meaning is so indefinite and ambiguous, Claim 144 is invalid pursuant to 35 U.S.C. § 112(2). Pave Tech counters that "substantial" as used in Claim 144 would sufficiently inform one skilled in the art of paving installations about the claim.

Section 112(2) requires that:

The specification; shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention.

The Federal Circuit has consistently held that when evaluating a claim for particularity and distinctness, its terms must be understandable to one skilled in the art. Markman, 52 F.3d at 986; see also Amgen, Inc. v. Chugai Pharmaceutical Co., Ltd., 927 F.2d 1200 (Fed. Cir. 1991). In Amgen, the Federal Circuit held that the term "about" as used in the phrase "at least about 160,000" was indefinite and rendered the claims invalid. Amgen, 927 F.2d at 1217. However, the amgen court was quick to caution that its holding applied only to the facts of that case and that the term "about" "may be acceptable in appropriate fact situations." Amgen, 927 F.2d at 1217.

Snap Edge urges the same result here, arguing that the term "substantial" renders the meaning of Claim 144 in doubt. In support of its position, Snap Edge argues that Pave Tech's own technical expert, Dr. Matthew W. Witczak ("Dr. Witczak") has provided inconsistent opinions in his 1993 deposition and recent affidavit as to the meaning of the term "substantial." Further, Snap Edge suggests that Pave Tech's reliance for this motion on the very general dictionary definition of "substantial" improperly negates the meaning of the word it modifies: "Forces." Ultimately, Snap Edge suggests that "substantial" cannot be sufficiently defined and that, therefore, Claim 144 must be invalid.

In light of Markman, Snap Edge urges this Court to revisit its motion for summary judgment on the issue of invalidity which was denied by Judge Wayne Andersen (adopting the Report and Recommendation of Magistrate Judge Joan B. Gottschall) in 1994. The Court finds that it has neither the authority nor the inclination to do so since such a "revisitation" would amount to a "reconsideration" of circumstances not properly before this court. The Court will therefore confine its analysis to claim interpretation as directed under Markman.

In support of this motion, Pave Tech has provided the following definition as extrinsic evidence for claim construction purposes: substantial (adjective) is defined as "consisting of, relating to, sharing the nature of, or constituting substance; not seeming or imaginary; not illusive." (Exh. 5, p. 7) citing Webster's Third New international Dictionary (1986) p. 1986.

The Court disagrees with Snap Edge's conclusions and finds that the term "substantial" as used in the context of paving installations described in the '550 Reissue Patent is sufficiently precise to inform one skilled in the art. Dr. Witczak, as one with "extraordinary" 10 skill in the art of pavements, has testified that in the context of paving installations like those described in the '550 Reissue Patent which can be subjected to a wide variety of loads, it is understood that no explicit quantification can be made for such forces. Thus, the term "substantial" cannot be interpreted to mean a specific quantity; rather it describes a range of loads from pedestrian to vehicular to occasional heavy truck. (Witczak Dep. at 135-146; Witczak Aff., PP 32-34). 11 Dr. Witczak further testified that while tractor-trailers and commercial aircraft would certainly produce "substantial" forces, it is understood from the patent that this invention would not be applied in installation subject to such forces. (Witczak Aff., P 35). 12 In addition, the Court finds that Pave Tech's reference to a dictionary definition of "substantial" does not violate claim interpretation rules. The definition is consistent with Dr. Witczak's interpretation and helps to explain that Claim 144 relates to a range of forces and distinguishes this invention from other restraints used strictly in landscaping as discussed in the specification.
10 See Witczak Dep. at 242.

32. A properly constructed paving installation as described about is capable of withstanding substantial horizontal forces that may be generated under traffic loadings on the paving installation. A strong restraint is necessary to maintain the paving stones in their horizontal direction and is provided for in the reissue patent. (Col. 10, lns. 28-29).

33. The "load dynamics" operating over the paving installation determine the extent of the horizontal forces. The precise magnitude of the horizontal force that will be transmitted to the edge restraint is a complex function due to many variables, e.g., vehicle gear configuration, tire loads and contact pressures, traffic speeds, mode of operation (standing, turning, accelerating, braking) as well as the cross-section of the paving installation and the distance from the edge restraint to the geometric center of the load. A properly constructed paving installation as described above, will function properly in accordance with the reissue patent specification when loaded with anything from pedestrian traffic up to heavy truck traffic which would produce substantial horizontal forces. (Col. 5, lns. 46-51).

34. Being one of ordinary skill in the art, I understand from reading the reissue patent-in-suit; that a paving installation, properly constructed in accordance with the reissue patent, can experience substantial horizontal forces in use without failure. Such substantial horizontal forces can be generated as described in the patent by loads up to heavy trucks travelling over the paving installation. (Col. 5, lns. 46-51).

12 35. One skilled in the art would understand the limits to which the paving installation described in the reissue patent would be applicable for any given installation. Clearly, for example, the paving installation using the edge restraint described in the reissue patent would not be applicable for typical heavy interstate tracto-trailer [sic] vehicles nor for heavy commercial aircraft such as a Boeing 747.

The Court finds that the term "substantial," when considered in the light of the entire claimed invention, is as accurate as the subject matter permits and provides sufficient guidance to one skilled in the art of paving stone installations. See Orthokinetics, Inc. v. Safety Travel Chairs, Inc., 806 F.2d 1565, 1576 (Fed. Cir. 1986) (finding that the term "so dimensioned" to be sufficiently accurate given the various types of automobiles to which the invention applied). Given that pedestrians and vehicles come in a myriad of shapes and sizes, it would be impossible to set forth every possible specific force. Thus, the use of the term "substantial forces" adequately explains that walkways and driveways which incorporate this interlocking paving installation can be subjected to a limited range of forces - from pedestrians up to heavy trucks.
zygomatic arch along the lower side of the orbit of a user, said patch being of sufficient extent to substantially cover the skin area on the zygomatic arch when applied to said skin area.

The second area of controversy is contained in the third sub-paragraph of claim 1, which recites

a light absorbing surface on a second face of the patch for absorbing incident light rays directed toward said skin area; said light absorbing surface being dark in color to reduce glare by substantially preventing light from reflecting from said skin area of the zygomatic arch toward the eyes of the wearer, said light absorbing surface being resistant to running caused by perspiration.

Defendant contends that the first section must be construed to cover the entire zygomatic arch, which is the arch of bone extending from the cheekbone to the side of the skull just in front of the ear, in other words, the whole of the cheekbone, including not only the under-the-orbit portion shown in Fig. 1 of the patent specifications, but also the portion of the cheekbone on the side of the face. Alternatively, defendant contends, the section must be found indefinite as a matter of law because the term "substantially cover" is not sufficiently precise to tell the person of ordinary skill in the art what he must do to avoid infringement.

Defendant's suggested construction makes no sense. Although defendant argues that the court should look to the dictionary definition of zygomatic arch, which would lead to the conclusion it proposes, the claim language, the specifications and common sense militate against doing so. The inventors claim an "under-eye" device; a patch extending beyond the eye would not be an under-eye device. The claim itself specifies that the patch is to be applied to the skin area on the zygomatic arch "along the lower side of the orbit of the user." '909 Pat., col. 3, Ins. 54-55. Also, the device is designed to prevent light from reflecting from the skin area to the wearer's eye; a side patch would be unlikely to fulfill this purpose.

The specifications start with Fig. 1, which shows a small kidney bean-shaped device located right under each eye of the wearer. Although defendant argues that "a figure cannot be relied upon for the precise dimensions of a claim limitation," Dft.'s Br., dkt. # 39, at 2, and cites Hockerson-Halberstadt, Inc. v. Avia Group Int'l, 222 F.3d 951, 956 (Fed. Cir. 2000), in support of its argument, Hockerson-Halberstadt is easily distinguishable. In that case, the court held that the patent drawings could not be used to determine measurements where the claims referred to quantitative relationships among the components of a particular device and the specifications were silent on the same relationships. "It is well established that patent drawings do not define the precise proportions of the elements and may not be relied on to show particular sizes if the specification is completely silent on the issue." Id. The court noted that "figures in a patent are not drawn to scale unless otherwise indicated." Id. In other cases, however, the Federal Circuit has approved the use of patent drawings in understanding the claims of a patent. See, e.g., CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1153 (Fed. Cir. 1997) (holding patent drawings highly relevant to understanding claims). See also Phillips v. AWH Corp. 415 F.3d 1303, 1315 (Fed. Cir. 2005) (holding specification highly relevant to claim construction analysis). Even if the claims left any doubt about where the patch is to be placed, the specifications would eliminate the doubt.

Finally, common sense and experience dictate construction of the claimed patch as one that is applied to the bony (zygomatic) arch immediately below the eye. The reason that athletes use using charcoal and other materials to black out that section is because it is the area from which light can reflect back into the athlete's eyes.

As to the second area of controversy, relating to the glare reduction requirement, defendant argues that the claim should be construed as requiring a black patch and one that is intended to be used primarily for the purpose of reducing glare to improve sight. Plaintiff counters by pointing out that nothing in claim 1 or the specifications requires an entirely black patch or even one that is mostly black. The claim provides for a surface that is "dark in color." Col. 3, In. 68. It does not specify black as the "dark color." Dependent claim 7 adds the limitation: "wherein said light absorbing surface is black." If independent claim 1 were interpreted as requiring a black patch, claim 7 would be superfluous and would not have been approved by the examiner.

Plaintiff denies that the patent requires patches that improve the user's eyesight. Plaintiff is correct. The patent claims a patch that substantially prevents light from reflecting from the zygomatic arch toward the wearer's eyes; it says nothing about improving sight. One would expect that sight would improve if protected from glare, but this is not a claim requirement.
Accordingly, for claim construction purposes, "substantial coverage" means a patch large enough to cover the skin area on the zygomatic arch when applied to said skin area; "substantial" means "largely, but not necessarily wholly, that which is specified," LNP Engineering Plastics, Inc. v. Miller Waste Mills, Inc., 275 F.3d 1347, 1354 (Fed. Cir. 2001), or approximately the same size as the patch shown in the patent drawings. In the third section of claim 1, "said skin area of the zygomatic arch" is the area under the eye; "substantially" preventing reflected light means, again, "largely, but not necessarily wholly, that which is specified." "Wherein said light absorbing surface is black" is construed to mean a patch that includes a black light-absorbing surface.

Having construed the claims, I find no problem of indefiniteness. The substantial coverage limitation is definite enough to give clear warning of what constitutes infringement; the reference to the zygomatic arch along the lower side of the orbit of a user is clear; the patent gives sufficient guidance for determining how much coverage is "substantial" as I have explained and the patent makes it clear that preventing light from reflecting into the eyes of the user will follow if the patch is about the same size as the one pictured in the specifications, dark in color and have a non-reflective surface to reduce glare.

In contrast to the claim phrases construed above, in some instances the Applicant did claim a parts washer configuration where the biodegradation is claimed to occur at or near the surface of the fluid. For example, dependent claim 2 of the '110 patent recites a system for cleaning hydrocarbons from a part "wherein the fluid defines a fluid surface in the tank, and wherein [a] substantial portion of the microorganisms live in the fluid proximate to said fluid surface." '110 patent, col. 8, ll. 42-44. Similarly, claim 3 recites "[t]he combination of claim 2, wherein a substantial portion of the microorganisms and hydrocarbons accumulate proximate to said fluid surface such that a substantial amount of biodegradation takes place proximate to said fluid surface." Id., col. 8, ll. 45-49. In these claims, the parties dispute the meaning of "substantial."

Plaintiff ChemFree argues that the term "substantial" as used in these claims should mean "a part of the whole that is considerable in extent relative to the whole" or "a quantity that is considerable in extent." J. Walter argues that "substantial" should mean a majority, or more than 50%. (E.g., Def.'s Opening Brief at 35 ("Although the term 'substantial portion' has more than one ordinary meaning, it should be construed to mean 'majority' because it is used throughout the entire intrinsic record in a manner consistent with this ordinary meaning.").)

The intrinsic record is unhelpful in discerning a precise meaning of the term. For instance, the specification notes that "a large percentage of the microorganisms and organic contaminants will tend to accumulate proximate to the surface of the cleaning fluid 72 such that a large portion of the biodegradation takes place proximate to the surface of the cleaning fluid 72." '110 patent, col. 6, l. 66 - col. 7, l. 3 (emphases added). Notably, this discussion of biodegradation is made with respect to a preferred embodiment of the invention, which militates against its use in limiting the term. Moreover, these relative terms do little to inform what "substantial" or "large" mean in context with the whole.

Nor does the prosecution history enlighten the meaning of "substantial." In a Preliminary Amendment, made prior to any action by the PTO in that particular application, Applicant added new claims and made the following remarks:

As recited in claims 23 and 31-37, as now amended, the fluid defines a fluid surface in the tank and a substantial portion of the microorganisms and hydrocarbons washed from the part tend to accumulate proximate to the fluid surface so that a substantial amount of the biodegradation takes place proximate to the fluid surface. Such a feature is not taught by the cited references.

'110 Patent File History, Applicant's Preliminary Amendment at 7. The amendment also states that

[b]y having the biodegradation occur primarily at the fluid surface within the tank, a vapor barrier is created within the tank to minimize evaporation of the cleaning fluid and thus minimize the amount of cleaning fluid that must be replenished.

Id. While these remarks certainly make clear that the Applicant intends the systems in these claims to have a "substantial" amount of biodegradation take place proximate to the fluid surface, they do little to inform the meaning of what a
"substantial" amount of microorganisms or biodegradation is. Despite the words "large" and "primarily" in the specification and prosecution history, nowhere does the intrinsic record of the '110 patent indicate that "substantial" as used therein should have anything other than its plain and ordinary meaning. Certainly, the record does not evidence an intent to redefine the term to mean an amount more than 50%. Cf. Phillips 415 F.3d at 1316 ("[O]ur cases recognize that the specification may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess. In such cases, the inventor's lexicography governs."). If Applicant had intended for substantial to have such meaning, it could have said so, or it could have used an equivalent term -- for example, "most" or "almost all."

"Without an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning." York Prods., Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1572 (Fed. Cir. 1996); see also Phillips 415 F.3d at 1312 ("[T]he words of a claim are generally given their ordinary and customary meaning.") (citation omitted). Dictionaries are often consulted to determine a term's plain and ordinary meaning. Phillips, 415 F.3d at 1314. The plain and ordinary meaning of "substantial" is a portion or amount that is considerable in quantity. See Merriam-Webster's Collegiate Dictionary 1170 (10th ed. 2001) ("considerable in quantity: significantly great").

The Court accords "substantial" its plain and ordinary meaning: "a portion or amount that is considerable in quantity." While this definition does not lend itself to numerical exactitude, it is faithful to the term's plain meaning. It will be a question for the factfinder to further delimit the scope of the phrase in determining whether the claim reads upon the accused device or whether a prior art reference invalidates the claim. This analysis may also require expert testimony.

**3840**

B. "in substantial alignment with"

The court finds that the term "in substantial alignment with" means "at least largely parallel to."

Claim 1 provides that the "longitudinal axis of said mounting base is in substantial alignment with a barrel of said firearm." For the term, "in substantial alignment with," Plaintiff proposes the construction, "at least largely parallel to." Defendant contends that the term "in substantial alignment with" should be construed as simply "parallel with." Because the term "substantial" is commonly used to import a sense of approximation, the court is unwilling to interpret the term "substantially parallel" as simply "parallel." Accordingly, the court will adopt Plaintiff's proposed construction.

**3841**

B. "Substantial Angular Length"

The term "substantial angular length" appears in Claims 1 and 9 of the '028 patent. In its summary judgment ruling, the Court concluded that the term "substantial angular length" should be construed using a functional definition. In light of that ruling, Rotron argues that the Court should adopt the following construction, which it phrases in functional terms: "The phrase 'substantial angular length' includes unmagnetized sectors of field portions of the rotor magnets that are wide enough to be substantially effective. There is no numerical limitation on this width in Claims 1-11." Rotron again argues that it is improper to read a numerical limitation into a claim that lacks such precision. See Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1551.

Nidec argues that "substantial angular length" should be construed as "large unmagnetized sectors of field portions of the rotor magnets which occupy an average angular extent throughout the axial length of the field portion which is greater than the 'relatively narrow' 10 to 20 degrees 'pole clearances' disclosed in the prior art." Nidec again maintains that a narrow definition and numerical specificity are necessary to distinguish the substantially unmagnetized segments of substantial angular length in the '028 patent from pole gaps or clearances disclosed in the prior art, such as Doemen '005, the patent from which the 10 to 20 degree requirement is derived. 3 Nidec also argues that Rotron's proposed functional definition...
improperly looks to the prosecution history to provide a disclosure-specially, the purpose of the substantially unmagnetized sectors-that is not apparent from the specification itself. 4

3 Claim 12 of the '028 patent states the following: "The magnet according to claim 9, wherein each null sector has an effective arcuate extent greater than 20 degrees mechanical." As Nidec indicates, under the rule of claim differentiation, narrow claim limitations cannot be read into broad ones. See Transmatic, Inc. v. Gulton Indus., Inc., 53 F.3d 1270, 1277 (Fed. Cir. 1995). Nidec explains that it has abandoned its position, rejected by the Court in its summary judgment ruling, that the limitation contained in Claim 12 should be read into Claim 1. Instead, it maintains that its present argument that the term "substantial angular length" should be construed as meaning sectors that are "greater than the 'relatively narrow' 10 to 20 degrees 'pole clearances'" in the prior art does not violate the doctrine of claim differentiation because it is less restrictive than the requirement of Claim 12.

4 35 U.S.C. § 112 P6 provides that "an element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof; and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." See 35 U.S.C. § 112, P6. "Without the term 'means,' a claim element is presumed to fall outside means-plus-function strictures . . . However, that presumption can collapse when an element lacking the term 'means' nonetheless relies on functional terms rather than structure or material to describe performance of the claimed function." Micro Chemical, Inc. v. Great Plains Chemical Co., 194 F.3d 1250, 1257 (Fed. Cir. 1999); see also Al-Site Corp. v. VSI Int'l, Inc., 174 F.3d 1308, 1318 (Fed. Cir. 1999). Nevertheless, if the claim contains functional language, but also discloses the structure within the language of the claim, § 112, P6 is not applicable. See Personalized Media Communications, LLC v. International Trade Comm'n, 161 F.3d 696, 704 (Fed. Cir. 1998).

Here, Nidec suggests that Rotron's proposed meaning for the term "substantial angular length" fails to adhere to the requirements of § 112, P6 because it includes some functional language, as it states that the length of the segments must be great enough to render them "substantially effective." However, the word "means" does not appear in the claim, and the claim clearly defines its elements in structural terms. Nor is there other evidence that the patentee intended to assert a means-plus-function claim. See, e.g., Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584 (Fed. Cir. 1996) ("In this case . . . the element in question did not use conventional "means-plus-function" language, no other element of the claim was in means-plus-function form, and nothing cited to us from the prosecution history or elsewhere suggests that the patentee intended to claim in that fashion."). Further, a patent applicant is free to define features of an apparatus functionally. See In re Schreiber, 128 F.3d 1473, 1478 (Fed. Cir. 1997); In re Swinehart, 58 C.C.P.A. 1027, 439 F.2d 210, 212 (C.C.P.A. 1971). Therefore, the Court concludes that the term "substantial angular length" should not be construed as a means-plus-function claim.

As stated above, Claims 1 and 9 both are independent claims. Neither defines "substantial angular length" and the ordinary meaning of the term is not apparent from the claims. When the claims do not provide a definition, the specification is generally "the single best guide to the meaning of a disputed term." Vitronics, 90 F.3d at 1582. "The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication." Id. Here, however, the specification provides no express definition of the term. Nevertheless, as Rotron points out, the specification does indicate that the size of the substantially unmagnetized segments of substantial angular length-like all the magnetized segments-differ based on the purpose for which they are used. It states, "the number and lengths of the unmagnetized and magnetized segments of the field portion, and the number and relative sizes of the commutation segments will differ with the number of poles of a particular brushless DC motor and the particular commutation circuit, for example," '028 pat., col. 4, ll. 38-43. The specification further indicates that the permanently magnetized segments of the integral magnet are "each of the required size, angular extent and polarity for its particular purpose." '028 pat., col. 1, ll. 48-51. This statement implies that the length of the unmagnetized segments of the field magnet varies.

The fact that the substantially unmagnetized segments of substantial angular length "occupy about 45 degrees of circular arc" in the preferred embodiment is of no moment. "It is usually incorrect to read numerical precision into a claim from which it is absent, particularly when other claims contain the numerical limitation" Modine v. United States Int'l Trade
Comm'n, 75 F.3d 1545, 1551 (Fed. Cir. 1996). Moreover, "it is well established that the preferred embodiment does not limit broader claims that are supported by the written description." Toro Co. v. White Consol. Indus. Inc., 199 F.3d 1295, 1301 (Fed. Cir. 1999); see also Burke, Inc. v. Bruno Indep. Living Aids, Inc., 183 F.3d 1334, 1341 (Fed. Cir. 1999) ("An attribute of the preferred embodiment cannot be read into the claim as a limitation."). While this rule does not apply when the preferred embodiment is described as the specification as the invention itself, rather than one way of utilizing it, see Modine, 75 F.3d at 1551, here the preferred embodiment states that it "is not to be construed as limiting the scope of this invention," thus making it clear that the preferred embodiment is simply one example of how the invention may be utilized. '028 pat., col. 5, ll. 48-49.

The court next turns to the prosecution history to construe this term. As explained above, Nidec argues that the proper construction of "substantial angular length" should be limited based upon the prior art, again referring to Doemen '005. However, as explained above, the patent applicant's submission to the patent examiner indicates that the substantially unmagnetized sectors in the '028 patent are distinguished from the pole gaps or clearances in Doemen '005 and '104 Muller based upon the nature of the magnetization pattern. Thus, Rotron's contention that null and pole clearance size should not be compared appears to be supported by the prosecution history—they indeed appear to be two different phenomena. While it is necessary to construe amount of the magnetization of the sectors with some specificity to distinguish the sectors from the prior art, doing so obviates the need to read the same specificity into the length of the substantially unmagnetized sectors. The Court therefore declines to construe the term "substantial angular length" with any precise numerical limitations derived from Doemen '005. The prosecution history does not indicate that this sort of specificity was intended by the patentee. 5 Modine, 75 F.3d at 1551.

--- Footnotes ---

5 Given that the Court will not adopt Nidec's proposed construction, it will not determine whether "average angular extent" is the proper measure of the size of the substantially unmagnetized sectors.

--- End Footnotes ---

Rotron's proposed functional definition reflects some statements in the prosecution history, which suggests that the "large null sectors of the field magnet portion can be provided as best suits the stator lamination geometry for improved starting, least torque ripple, and maximum torque," Defs.' Ex. 6, at 7, and that purpose of the substantially unmagnetized sectors is to "create a substantial effective angular null." Id. at 12 (emphasis added). Similarly, extrinsic evidence in the form of the inventor's response during a deposition indicates that substantial angular length should be determined based upon "whether or not the fan operates properly." 6 Defs.' Ex. 13, at 146. However, Rotron's proposed meaning—that the substantially unmagnetized sectors are "wide enough to be substantially effective"—should not be adopted because it improperly broadens the disputed term. See Markman I, 52 F.3d at 980. Conversely, while it may be possible to further define the function of the substantially unmagnetized sectors of substantial angular length based on the purpose set forth in the prosecution history (the prevention of cogging and related problems), "limitations cannot be read into the claims from the specification or prosecution history" Burke, 183 F.3d at 1340. Instead, the Court concludes that the term "substantial angular length" needs no further construction, particularly given the fact that the magnetization of the sectors has been defined with some specificity, and the fact that the claims and the other portions of the specification provide no guidance for the proper definition of "substantial angular length." No further specificity or precision is warranted by the language of the claim and other evidence. See PPG Indus. v. Guardian Indus. Corp., 156 F.3d 1351, 1355 (Fed. Cir. 1998).

--- Footnotes ---

6 The exchange was as follows:

Q: Is what determines whether a null is of substantial angular length whether or not the fan operates properly?

...  

A: I believe I've used that term on several past depositions. That is correct.

Def's.' Ex. 13, at 146.
With trial set to begin on Monday, September 12, the parties have filed a number of motions. Plaintiff has asked the court to exclude evidence or argument that the claims of the '909 patent are indefinite; defendant has asked for judgment as a matter of law on the issue of indefiniteness under 35 U.S.C. § 112, P 2 and for a judicial construction of the claims 1, 3 and 7 of the patent. Although the motions are not thoroughly briefed, the briefs that have been filed are sufficient to allow a ruling on the pending motions. (Plaintiff's brief in support of its motion to exclude evidence on the alleged indefiniteness of the '909 patent addresses the same legal issues as defendant's brief in support of its motion for a judicial determination that the '909 patent is indefinite as a matter of law and the opposing briefs on claim construction address the indefiniteness arguments.) Plaintiff opposes defendant's late filed request to move for judgment on indefiniteness, arguing that it is far too late to be raising an issue that should have been raised before the time for filing motions for summary judgment had expired. Plaintiff makes a good point, but the issue is a straightforward one and its resolution will simplify the task for trial. Because I am resolving it in plaintiff's favor, plaintiff is not prejudiced by the late filing.

The language at issue is contained in independent claim 1 and dependent claims 3 and 7. The first section in dispute provides:

a replaceable pliable sheet material patch having a first face for generally conformable application to the skin area on the zygomatic arch along the lower side of the orbit of a user, said patch being of sufficient extent to substantially cover the skin area on the zygomatic arch when applied to said skin area.

The second area of controversy is contained in the third sub-paragraph of claim 1, which recites

a light absorbing surface on a second face of the patch for absorbing incident light rays directed toward said skin area; said light absorbing surface being dark in color to reduce glare by substantially preventing light from reflecting from said skin area of the zygomatic arch toward the eyes of the wearer, said light absorbing surface being resistant to running caused by perspiration.

Defendant contends that the first section must be construed to cover the entire zygomatic arch, which is the arch of bone extending from the cheekbone to the side of the skull just in front of the ear, in other words, the whole of the cheekbone, including not only the under-the-orbit portion shown in Fig. 1 of the patent specifications, but also the portion of the cheekbone on the side of the face. Alternatively, defendant contends, the section must be found indefinite as a matter of law because the term "substantially cover" is not sufficiently precise to tell the person of ordinary skill in the art what he must do to avoid infringement.

Defendant's suggested construction makes no sense. Although defendant argues that the court should look to the dictionary definition of zygomatic arch, which would lead to the conclusion it proposes, the claim language, the specifications and common sense militate against doing so. The inventors claim an "under-eye" device; a patch extending beyond the eye would not be an under-eye device. The claim itself specifies that the patch is to be applied to the skin area on the zygomatic arch "along the lower side of the orbit of the user." '909 Pat., col. 3, Ins. 54-55. Also, the device is designed to prevent light from reflecting from the skin area to the wearer's eye; a side patch would be unlikely to fulfill this purpose.

Defendant's suggested construction makes no sense. Although defendant argues that the court should look to the dictionary definition of zygomatic arch, which would lead to the conclusion it proposes, the claim language, the specifications and common sense militate against doing so. The inventors claim an "under-eye" device; a patch extending beyond the eye would not be an under-eye device. The claim itself specifies that the patch is to be applied to the skin area on the zygomatic arch "along the lower side of the orbit of the user." '909 Pat., col. 3, Ins. 54-55. Also, the device is designed to prevent light from reflecting from the skin area to the wearer's eye; a side patch would be unlikely to fulfill this purpose.

The specifications start with Fig. 1, which shows a small kidney bean-shaped device located right under each eye of the wearer. Although defendant argues that "a figure cannot be relied upon for the precise dimensions of a claim limitation," Dft.'s Br., dkt. # 39, at 2, and cites Hockerson-Halberstadt, Inc. v. Avia Group Intl, 222 F.3d 951, 956 (Fed. Cir. 2000), in support of its argument, Hockerson-Halberstadt is easily distinguishable. In that case, the court held that the patent drawings could not be used to determine measurements where the claims referred to quantitative relationships among the components of a particular device and the specifications were silent on the same relationships. "It is well established that patent drawings do not define the precise proportions of the elements and may not be relied on to show particular sizes if the specification is completely silent on the issue." Id. The court noted that "figures in a patent are not drawn to scale unless otherwise indicated." Id. In other cases, however, the Federal Circuit has approved the use of patent drawings in understanding the
claims of a patent. See, e.g., CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1153 (Fed. Cir. 1997) (holding patent
drawings highly relevant to understanding claims). See also Phillips v. AWH Corp. 415 F.3d 1303, 1315 (Fed. Cir. 2005)
(holding specification highly relevant to claim construction analysis). Even if the claims left any doubt about where the
patch is to be placed, the specifications would eliminate the doubt.

Finally, common sense and experience dictate construction of the claimed patch as one that is applied to the bony
(zygomatic) arch immediately below the eye. The reason that athletes use using charcoal and other materials to black out
that section is because it is the area from which light can reflect back into the athlete's eyes.

As to the second area of controversy, relating to the glare reduction requirement, defendant argues that the claim should be
construed as requiring a black patch and one that is intended to be used primarily for the purpose of reducing glare to
improve sight. Plaintiff counters by pointing out that nothing in claim 1 or the specifications requires an entirely black patch
or even one that is mostly black. The claim provides for a surface that is "dark in color." Col. 3, In. 68. It does not specify
black as the "dark color." Dependent claim 7 adds the limitation: "wherein said light absorbing surface is black." If
independent claim 1 were interpreted as requiring a black patch, claim 7 would be superfluous and would not have been
approved by the examiner.

Plaintiff denies that the patent requires patches that improve the user's eyesight. Plaintiff is correct. The patent claims a
patch that substantially prevents light from reflecting from the zygomatic arch toward the wearer's eyes; it says nothing
about improving sight. One would expect that sight would improve if protected from glare, but this is not a claim
requirement.

Accordingly, for claim construction purposes, "substantial coverage" means a patch large enough to cover the skin area on
the zygomatic arch when applied to said skin area; "substantial" means "largely, but not necessarily wholly, that which is
specified," LNP Engineering Plastics, Inc. v. Miller Waste Mills, Inc., 275 F.3d 1347, 1354 (Fed. Cir. 2001), or
approximately the same size as the patch shown in the patent drawings. In the third section of claim 1, "said skin area of the
zygomatic arch" is the area under the eye; "substantially" preventing reflected light means, again, "largely, but not
necessarily wholly, that which is specified." "Wherein said light absorbing surface is black" is construed to mean a patch
that includes a black light-absorbing surface.

Having construed the claims, I find no problem of indefiniteness. The substantial coverage limitation is definite enough to
give clear warning of what constitutes infringement; the reference to the zygomatic arch along the lower side of the orbit of
a user is clear; the patent gives sufficient guidance for determining how much coverage is "substantial" as I have explained
and the patent makes it clear that preventing light from reflecting into the eyes of the user will follow if the patch is about
the same size as the one pictured in the specifications, dark in color and have a non-reflective surface to reduce glare.

A. The Claimed Invention

This case involves the structure of slurry tanks. Slurry tanks are used to store and process chemicals and organic waste
products (e.g., manure) that retain value as useful inputs (e.g., fertilizer) into other processes. Large storage tanks house
these waste compounds in liquid or semisolid form between their production and their subsequent use. The liquid and solid
components of these waste compounds tend to separate when stored, with solid particles either forming a crust on the top of
the tank and/or falling to the bottom of the tank. Productive use of the stored compound requires remixing both to suspend
the heavy solid particles within the liquid and to ensure that the resulting suspension is uniform. One standard approach has
been to stir the mix continuously to avoid settling. Because continuous mixing can be expensive, however, tank designers
sought ways to store the mixtures in a still tank, to allow the settling to occur, and to remix only when necessary for use.
The '414 patent addressed these concerns.

The '414 patent has a total of 11 claims. Claims 1 and 8 are independent; the remaining nine claims are dependent. The invention is a method and apparatus for handling wastewater slurries: a storage tank equipped with submerged agitators capable of generating a flow of liquid throughout the tank. The disagreement between the parties turns on the interpretation of four phrases contained in Claim 1, and identical phrases in independent Claim 8. Claim 1 claims:

Apparatus for storing a slurry having solid and liquid components, comprising:

a storage tank defining a volume for holding a body of liquid and solid slurry components, including a floor of generally circular configuration and having a center; said storage tank further including an outer surrounding wall positioned generally at a radial distance from the center;

at least two flow generating means positioned to be submerged within the liquid and solid slurry components for generating flow of at least one of the slurry components along a rotational direction, each of said flow generating means being disposed at distances from the center ranging between approximately 30 percent and 70 percent of said radial distance;

each of said first and second flow generating devices pointed in the direction for generating flows of the liquid and solid components from the respective flow generating means directed in the same rotational sense,

[1] said first and second flow generating means being directed at an angle to the radius to generate flows with tangential components of flow to impart a rotational movement of the entire body of liquid and solid components;

each of said first and second flow generating means being pointed toward the outer surrounding wall for generating

[2] a substantial helical flow path of the liquid and solid components therein

[3] with the liquid and solid components traveling outwardly, across the tank floor from the center portion of the tank toward the tank wall and then upwardly along the tank outer surrounding wall to a first point and then inwardly along an upper portion of the body toward the center of the tank and then downwardly toward the tank floor, and then outwardly to a second point spaced circumferentially in the direction of rotation of the entire body of liquid, the liquid and solid components continuing to travel in the helical path as the entire body of liquid and solid components continues to rotate;

a pressure source coupled to the first and second flow generating means to generate directed streams from the flow generating means to rotate the body of liquid and solid components and to cause the flow in the helical path; and

[4] said flow generating means creating a substantially volume filling flow of at least one of the slurry components within said storage tank which mixes the liquid and solid slurry components to form a substantially homogeneous slurry suitable for unloading from said storage tank using liquid handling devices.

'414 patent, cols. 8-9 (emphases added). 1

--- Footnotes ---
1 The patent claim language does not contain the phrase numbering. The district court introduced the enumeration of phrases 1 through 4 in Claim 1 for reference purposes.

--- End Footnotes ---

B. The Prosecution History

Original Claim 1, filed with the application that matured into the '414 patent with the United States Patent and Trademark Office ("PTO"), contained phrase 4 but did not contain phrases 1, 2, or 3. Specifically, original Claim 1 read:
Apparatus for storing a slurry having solid and liquid components, comprising:

a storage tank defining a volume for holding the liquid and solid slurry components, including a floor of generally circular configuration and having a center portion, said storage tank further including an outer surrounding wall positioned generally at a preselected radial distance from the center portion; and

at least two flow generating means positioned to be submerged within the liquid and solid slurry components for generating flow of at least one of the slurry components along a preselected direction, said flow generating means being disposed only at distances from the center ranging between approximately 30 percent and 70 percent of said preselected radial distance;

[4] said flow generating means creating a substantially volume filling flow of at least one of the slurry components within said storage tank which mixes the liquid and solid slurry components to form a substantially homogeneous slurry suitable for unloading from said storage tank using liquid handling devices. 2

--- Footnotes ---

2 We maintained the labeling of phrase 4 in original Claim 1 to parallel the district court's labeling in Claim 1 of the '414 patent.

--- End Footnotes ---

The patent examiner rejected the original Claim 1 as obvious in light of the prior art. The examiner also indicated that the original Claim 1 was "generic" and required the applicant to "elect a single disclosed species for prosecution" under 35 U.S.C. § 121. Amended Claim 1 added phrases 1, 2, and 3, and introduced other minor changes not at issue here.

Amended Claim 1 introduced new limitations on the claimed flow. Whereas original Claim 1 referred only to a "flow," amended Claim 1 required "a substantial helical flow path" (phrase 2) traveling "outwardly, across the tank floor from the center portion of the tank toward the tank wall and then upwardly along the tank outer surrounding wall to a first point and then inwardly along an upper portion of the body toward the center of the tank and then downwardly toward the tank floor, and then outwardly to a second point spaced circumferentially in the direction of rotation of the entire body of liquid" (phrase 3). The PTO accepted Claim 1 as amended and issued the patent. Amended Claim 1 issued as Claim 1 of the '414 patent.

C. Pre-Filing Conduct

The '414 patent was assigned to Liquid Dynamics' predecessor, Great Lakes Aqua Sales and Service, Inc. ("Great Lakes"). To support its counterclaims of invalidity and inequitable conduct, Vaughan alleged that Great Lakes made, used, and sold three mixing systems having the characteristics originally claimed in the '414 patent more than a year before filing the original application--and submitted documentary evidence to support these allegations.

D. The District Court Decision

Liquid Dynamics claimed that 47 of Vaughan's customized slurry tank systems infringe the '414 patent. Vaughan denied the allegations and counterclaimed for summary judgment on grounds of non-infringement, invalidity, and inequitable conduct. Vaughan subsequently moved for summary judgment on grounds of non-infringement, invalidity, and inequitable conduct. The district court disposed of all issues in a single ruling. See generally, Liquid Dynamics.

On the matter of claim construction, the trial judge noted that "phrases 1 and 4 are unambiguous and claim construction is unnecessary," Liquid Dynamics at *20, but that phrases 2 and 3 required, "proper claim interpretation [by] examination of the claim language, the patent specification, and the prosecution history." Id. at *10.

Both parties suggested interpretations that treated phrases 2 and 3 as a single limitation. Vaughan suggested that phrases 2 and 3 require:
a helical flow path consisting of the bottom segment of the path extending essentially radially from the center of the tank to the peripheral wall, with the bottom segment being immediately adjacent to the floor of the tank; an outer segment extending essentially vertically upward along the outer wall; an upper segment extending essentially radially along the upper portion of the body of slurry in the tank from the outer wall to the center of the tank; and an inner segment extending essentially vertically downward at the center; all segments no more than a negligible radial distance from the center.

Id.

Liquid Dynamics, on the other hand,

advanced a broader definition of substantial helical flow: a largely or generally spiral-like flow path; a perfect helical path is not required; components of the slurry follow a path generally looping away from the center portion of the tank toward the tank's wall, upwardly toward the upper portion of the tank, then toward the center portion, and then downwardly.

Id.

The district court accepted Vaughan's proffered claim construction primarily because "the claim's plain language describes a flow path that emanates from the tank center and returns to the center after one rotation," id. at *10, and because two of the patent's figures, Figures 5 and 6, illustrate a perfectly helical flow. Id. at *12-*14. The district court further noted that the narrowing amendments introduced to Claim 1 during prosecution to limit what had been a generalized flow pattern to the substantially helical one following the specific directional outlines of phrase 3 not only supported Vaughan's interpretation of the claim language, id. at *15, but also narrowed the range of infringing equivalents that Liquid Dynamics could assert. Id. at *28 (citing Warner-Jenkinson Co. v. Hilton Davis Chem. Co., 520 U.S. 17, 29-30, 137 L. Ed. 2d 146, 117 S. Ct. 1040 (1997); Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573 (Fed. Cir. 1996)).

Having thus construed the claims, the district court compared the claims to Vaughan's allegedly infringing products, following Markman v. Westview Instruments, Inc., 52 F.3d 967, 976 (Fed. Cir. 1995) (en banc), aff'd 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). Liquid Dynamics submitted evidence of infringement primarily through the testimony of its expert, Dr. Richard Lueptow. Dr. Lueptow had simulated a series of computational flow dynamics to illustrate both the path of a single particle (the "particle plots") and the velocity of that particle (the "vector plots") in each of Vaughan's tanks. Liquid Dynamics at *23. The district court noted that all of Dr. Lueptow's exhibits, as well as his testimony, had been based on Liquid Dynamics' construction of the claim, which the court had rejected. The district court ruled that no reasonable person considering the particle plots could conclude that Vaughan's tanks infringed the '414 patent given the district court's construction of the claim.

The district court did not comment on Dr. Lueptow's submitted vector plots. Dr. Lueptow had explained that:

In velocity vector plots, the many vectors in a specified plane (or slice) of the flow indicate the direction of flow (orientation of the vector) and the magnitude of the velocity in the plane of the slice (length of the vector).

The vector plots in vertical planes through the axis of the tank that I analyzed showed circulation of the fluid outward in the lower portion of the tank, upward in the outer portion, inward in the top portion of the tank, and downward near the center portion of the tank for each of the categories of Vaughan tanks.

Decl. of Dr. Richard M. Lueptow, PP 27-28. The court did not discuss the relationship between the flow pattern that Dr. Lueptow attributed to his vector plots and the flow pattern required under the court's claim construction.

The district court granted summary judgment in favor of Vaughan and mooted Vaughan's counterclaims for invalidity and inequitable conduct. Both parties timely appealed. We have jurisdiction of this appeal pursuant to 28 U.S.C. § 1295(a)(1).

DISCUSSION

A. Standard of Review

This court reviews the grant of summary judgment de novo. Genzyme Corp. v. Transkaryotic Therapies, Inc., 346 F.3d - 4503 -
A determination of patent infringement requires a two-step analysis. The court must first interpret the claim and determine the scope and the meaning of the asserted patent claims, and then compare the properly construed claims to the allegedly infringing device. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1454 (Fed. Cir. 1998). The first step, claim construction, is a matter of law that we review de novo. Id. at 1451. The second step is a factual question that we review following a trial for clear error. Bai v. L & L Wings, Inc., 160 F.3d 1350, 1353 (Fed. Cir. 1998). When conducting a de novo review of a district court's grant of summary judgment, however, we construe the facts in the light most favorable to the non-movant. Mazzari v. Rogan, 323 F.3d 1000, 1005 (Fed. Cir. 2003). To prove infringement, the patentee must show that the accused device meets each claim limitation, either literally or under the doctrine of equivalents. Deering Precision Instruments, L.L.C. v. Vector Distrib. Sys., Inc., 347 F.3d 1314, 1324 (Fed. Cir. 2003).

We review the district court's decision to moot Vaughan's counterclaims for abuse of discretion. Phonometrics, Inc. v. N. Telecom, Inc., 133 F.3d 1459, 1468 (Fed. Cir. 1998).

B. Claim Construction

Courts construe claims by considering the evidence necessary to resolve disputes about claim terms and to assign a fixed, unambiguous, legally operative meaning to the claim. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996).

It is well-settled that, in interpreting an asserted claim, the court should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history. Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language.

We examine this intrinsic evidence seriatim. "We look first to the claim language itself, to define the scope of the patented invention. As a starting point, we give claim terms their ordinary and accustomed meaning as understood by one of ordinary skill in the art." Dow Chem. Co. v. Sumitomo Chem. Co., 257 F.3d 1364, 1372 (Fed. Cir. 2001). We look to the written description for guidance "when the claim language itself lacks sufficient clarity to ascertain the scope of the claims." Deering, 347 F.3d at 1322. We also look at the written description "to determine whether the inventor has used any terms in a manner inconsistent with their ordinary meaning. The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication." Vitronics, 90 F.3d at 1582. "The specification contains a written description of the invention which must be clear and complete enough to enable those of ordinary skill in the art to make and use it. Thus, the specification is always highly relevant to the claim construction analysis." Id.

We look next to the prosecution history. When we use the prosecution history as source material, the prior art cited and the applicant's acquiescence with regard to that prior art indicate the scope of the claims, or in other words, what the claims do not cover. Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 65, 384 F.2d 391 (1967). Furthermore, "where the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003).

The district court identified the four disputed phrases in Claim 1 and determined that the claim language of phrases 1 and 4 was clear and needed no interpretation. The district court, however, was unable to interpret the helical flow pattern described in phrases 2 and 3 by reference to the claim language alone and considered the written description, the figures of the patent, and the prosecution history. The district court noted that two of the patent's figures, Figures 5 and 6, illustrate a perfect helical flow. In the prosecution history, the district court noted that Claim 1 as originally filed did not include language related to a helix--or to any other particular flow pattern--and that the amendments submitted to distinguish the claim from the prior art first introduced the "substantial helical" limitation. Based on these findings, the district court adopted Vaughan's suggested construction.
The district court's analysis was erroneous because Claim 1 was not ambiguous, and its plain meaning was not contradicted by the written description. The plain language of phrase 2 requires a "substantial helical flow." The term "substantial" is a meaningful modifier implying "approximate," rather than "perfect." In Cordis Corp. v. Medtronic AVE, Inc., 339 F.3d 1352, 1361 (Fed. Cir. 2003), the district court imposed a precise numeric constraint on the term "substantially uniform thickness." We noted that the proper interpretation of this term was "of largely or approximately uniform thickness" unless something in the prosecution history imposed the "clear and unmistakable disclaimer" needed for narrowing beyond this simple-language interpretation. Id. In Anchor Wall Systems v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1311 (Fed. Cir. 2003), we noted that: "nothing in the prosecution history . . . clearly limits the scope of 'generally parallel' such that the adverb 'generally' does not broaden the meaning of parallel. Accordingly, we hold that the phrase 'generally parallel' envisions some amount of deviation from exactly parallel," and that "words of approximation, such as 'generally' and 'substantially,' are descriptive terms 'commonly used in patent claims 'to avoid a strict numerical boundary to the specified parameter.'” Id. at 1311.

Similarly, the plain language of Claim 1 requires neither a perfectly helical flow nor a flow that returns precisely to the center after one rotation (a limitation that arises only as a logical consequence of requiring a perfectly helical flow). Because the plain language of the claim was clear and uncontradicted by anything in the written description or the figures, the district court should not have relied upon the written description, the figures, or the prosecution history to add limitations to the claim. Under such circumstances, relying on the written description and prosecution history to reject the ordinary and customary meanings of the words themselves is impermissible. Tex. Digital Sys. v. Telegenix, Inc., 308 F.3d 1193, 1204 (Fed. Cir. 2002). Courts construing claims must also remember that:

While . . . claims are to be interpreted in light of the specification and with a view to ascertaining the invention, it does not follow that limitations from the specification may be read into the claims. We recognize that there is sometimes a fine line between reading a claim in light of the specification, and reading a limitation into the claim from the specification.

Comark Communications v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998) (citations omitted).

The district court relied on the written description of Figures 5 and 6 to import the limitation of a perfectly helical flow. There is no language in the claim requiring such a perfectly helical flow. We have consistently warned against this approach to claim construction. See Amgen, Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1325 (Fed. Cir. 2003) (“Because the claims are best understood in light of the specification of which they are a part . . . courts must take extreme care when ascertaining the proper scope of the claims, lest they simultaneously import into the claims limitations that were unintended by the patentee.”); CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002) (explaining that the presumption of ordinary meaning cannot be rebutted "simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history"). Claim 1, properly construed, does not require a perfectly helical flow.

The district court here failed to differentiate between "helical" and "substantial helical." Claim 1, as properly construed, claims all flow patterns that are generally, though not necessarily perfectly, spiral, and that fill much, though not necessarily all, of the tank’s volume. This construction of the claim follows from the words "substantial helical flow" in phrase 2, the directional outline of phrase 3, and the words "substantially volume filling" in phrase 4.

In its claim interpretation, the district court defined the limitation "at least a substantial part of the entire height thereof" to mean "the ridge member must protrude from each of the sidewalls of the bed liner and must extend from near the bottom to near the top of the liner sidewall." In addition, the district court stated:

"Substantially the entire height thereof" simply means that the ridges must cover nearly the entire length of the sidewall. This limitation in the Claim was added by the patent applicant during prosecution of the patent, as was the case for the words: "vertically extending." A projection in the sidewall that does not span nearly the entire distance from the top to the bottom of the sidewall does not meet this limitation.
The claim language itself shows the accuracy of the district court's interpretation. Without an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning. Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 951, 28 U.S.P.Q.2D (BNA) 1936, 1938 (Fed. Cir. 1993); Smithkline Diagnostics, Inc. v. Helena Lab. Corp., 859 F.2d 878, 882, 8 U.S.P.Q.2D (BNA) 1468, 1471 (Fed. Cir. 1988); ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579, 6 U.S.P.Q.2D (BNA) 1557, 1560 (Fed. Cir. 1988). In this case, the patent discloses no novel uses of claim words. Ordinarily, therefore, "substantially" means "considerable in . . . extent," American Heritage Dictionary Second College Edition 1213 (2d ed. 1982), or "largely but not wholly that which is specified," Webster's Ninth New Collegiate Dictionary 1176 (9th ed. 1983). Thus, the modifier "substantially" conveys that the ridge members extend over most of the "entire height" of the sidewall portions. The district court's language captured well this meaning: "The ridge member . . . must extend from near the bottom to near the top of the liner sidewall."

"Substantial" in this context does not mean ample extension to accomplish the purpose of locking loads. The language "substantial part" expressly modifies the term "entire height." "Entire height," in turn, refers (via the antecedent marker "thereof") to "liner sidewall portions." Therefore, the claim language explicitly ties "substantial part" to the height of the sidewalls, not to the overall function of the invention. The language and syntax of the claim preclude a functional definition of "substantial part." In other words, if "substantial part" meant only ample height to accomplish a purpose, the claim would need to read "only so much height as necessary to affix a structure against movement." This redraft would essentially strip many words in the claim of their meaning.

The claim term "portions" also does not limit the "entire height" limitation to something less that the full height of the sidewalls. The context of the claim shows that the inventor used the term "liner sidewall portions" to distinguish the sidewalls from other portions of the overall invention such as the "liner floor portion" or "the liner frontwall portion." In context, the word "portion" does not refer to a part of the liner sidewall, but to the sidewall itself as a portion of the entire bed liner.

The specification also supports the district court's reading of this claim language. The embodiments disclosed in the '876 patent and its drawings show ridge members extending nearly the entire height of the sidewall. At no point does the specification suggest that "at least a substantial part of the entire height [of the sidewall]" means less than the entire height of the sidewall. Moreover, the specification uniformly uses the term "portion" to distinguish features of the invention from each other, not to refer to less than the entire feature. Even the reference at column 4, line 52, ("Sidewall portions 20 and 22 further contain rail overlay portions 27 containing notched parts 27A.") (emphasis added), identifies a feature, rather than limiting the feature's reach. Although the scope of the claims is not necessarily limited to the specific embodiments described in the specification, Amhil Enters., Ltd. v. Wawa, Inc., 81 F.3d 1554, 1559, 38 U.S.P.Q.2D (BNA) 1471, 1474 (Fed. Cir. 1996), the specification of the '876 patent does not provide any indication that the claim terms should be given anything other than their ordinary meaning. See North Am. Vaccine, Inc. v. American Cyanamid Co., 7 F.3d 1571, 1576, 28 U.S.P.Q.2D (BNA) 1333, 1337 (Fed. Cir. 1993).

In sum, the district court correctly construed the phrase "a substantial part of the entire height thereof." The limitation requires that the ridges must cover nearly the entire height of the sidewall portion of the invention.

The district court construed the "open for a substantial portion" limitation to require that the drain groove be "largely but not wholly open along the top." Construction Order at 9. The district court arrived at this construction based on events occurring during prosecution of the '350 patent. During prosecution, the applicant amended claim 1 by removing the term "upwardly open" and adding the "substantially open" limitation. Id. at 8. This amendment narrowed the claim by requiring the drain grooves to be open for a "substantial portion" of their lengths, thereby excluding from the scope of the claim drain grooves open for less than a substantial portion of their lengths. Thus, this court finds that the "substantially open" limitation calls for drain grooves that are "largely but not necessarily wholly open."
Claim 24

The process according to claim 1, wherein the process further comprises adding the recycled ladle metallurgy additive to the molten steel in granular form in at least two separate steps wherein a substantial portion of the granular recycled ladle metallurgy furnace slag is added before the raw materials.

The parties agree that Claim 24 has all the limitations of Claim 1. Defendant argues, and the Court agrees, that this claim calls for a "further" process which consists of at least two separate steps requiring "a substantial portion" of the slag to be added before the raw materials. The parties dispute whether a mixture is required as an additive. Defendant argues there is no way the claim can be performed in two steps without having a mixture in at least one of the steps (Tr. 61).

The key phrase here is "substantial portion" (Tr. 58). Plaintiff says this means up to 100% and Defendant says it must be less than 100%. Plaintiff's position is that neither Claim 1 nor Claim 24 mention a mixture of LMF slag and raw material and that Claim 24 calls for at least two steps in the process. Defendant's position is that Claim 1 is limited to a mixture and Claim 24 is limited to at least one step which is the addition of a mixture of recycled LMF slag and raw materials as described in Claim 1.

The Court agrees with the common sense reading that "a substantial portion" could be up to and including 100%, depending on the number of steps. As described by Plaintiff's counsel (Tr. 63):

If you want to do it in two steps, you keep them [recycled slag and raw materials] separate; you put them in separately. The substantial portion there is 100 percent. But the claim is drafted to accommodate 75 percent, and then all of the raw material, then 25 percent, . . . The claim is drafted to cover all of those possibilities. And it clearly does.

The Court's reading of Claim 24 is consistent with its reading of Claim 1.
plain meaning of "substantial" is appropriate. Each agree that the roller paths in the embodiments illustrated in the patent "are completely aligned in the radial direction with the corresponding jig or lower can support" and that claim 17 requires "substantial radial alignment, not complete radial alignment." 152 In support of their respective positions each cites the fourth definition of "substantial" contained in Webster's Third International Dictionary: "4 a: being that specified to a large degree or in the main . . . b: of or relating to the main part of something," 153 with Crown emphasizing "in the main," i.e., more than half. 154 The court finds these definitions less than helpful.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

152 D.I. 241 at 43; D.I. 294 at 41.
154 D.I. 241 at 44; D.I. 280 at 35.
- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

Rexam points out that the Federal Circuit has stated that "[t]he term 'substantial' is a meaningful modifier implying 'approximate,' rather than 'perfect.'" 155 Because the parties agree that the specification provides no helpful guidance, that the figures illustrate complete (or absolute) alignment, and that the claim requires something less than absolute alignment—"substantial alignment"—the court determines that Rexam's proposed construction more closely defines the "approximate," rather than "perfect" alignment to which the claim is limited.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

155 D.I. 294 at 41 (quoting Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 907 (Fed. Cir. 2005)).
- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

Consequently, the court adopts Rexam's proposed construction: "at or almost absolute radial alignment with said radial inward support."

The parties dispute what, exactly, has to have a refractive index match with the skin and what is meant by "substantial."
Plaintiff suggests this court adopt a construction used by the Northern District of California in litigation to which defendant was not a party. Lumenis, Inc. v. Palomar Med. Techs., Inc., No. C-02-5176, slip op. at 5-7 (N.D. Cal. April 19, 2004) (Docket # 28 Ex. H). The parties in that litigation focused exclusively on the meaning of "substantial" in the context of a definiteness challenge to the patent. I am fully persuaded by the Northern District of California's use of examples from the specification to illustrate the meaning of "substantial" and decline to follow defendant's suggestion of the term "approximately equal" because it adds no clarity to the claim language.

It is clear in the claim language that there must be a substantial refractive index match between the portion of the applicator "in contact with the skin surface" and the skin. '844 Patent col.17 ll.21-25. The claim does not specify how this should be accomplished. However, the specification discusses constructing the relevant part of the applicator out of material with a substantial match and/or placing a substance with a substantial match between the applicator and the skin. '844 Patent col.2 ll.59-67, col.7 ll.23-27, col.7 l.66 to col.8 l.5.

On its face, claim 1 requires "a flexible dielectric substrate having a [susceptor] thereon residing in a close proximal relation to a substantial surface portion of said food item." To construe the terms "close proximal relation" and "substantial surface portion," we look to the intrinsic evidence.

The specification discloses food items, i.e., a fish stick, potatoes, and onion rings, wrapped in a manner such that the susceptor, which coats dielectric wrapping material, remains adjacent to the surface of the food item throughout the cooking process. Consequently, "residing in a close proximal relation to … said food item," as utilized in claim 1, refers to a positional relationship between the susceptor and food item in which the susceptor remains closely adjacent to the food item throughout the cooking process.

The food item depicted in the specification, a fish stick, is completely wrapped with dielectric material. The susceptor, as disclosed and represented in the drawings, coats the entire inner surface of the dielectric material and envelopes the entire surface of the food item. Consequently, "a substantial surface portion of said food item" refers to a positional relationship between the susceptor and the food item in which the susceptor envelops a very large portion of the surface of the food item. The prosecution history also leads us to such an interpretation. While prosecuting claims 1 and 7 to allowance, General Mills distinguished its invention over a rigid dish containing a susceptor disposed thereon by maintaining that its invention can be wrapped for direct heat transfer in a manner previously unattainable due to the inflexibility of prior art susceptors.

Evenflo raises two defenses for non-infringement relative to claim 12. First, it contends that its liner does not "contact[ ] substantially all" of the support surface of the support tray. Second, it argues that its tray sets do not meet the "substantially the same configuration" limitation. Both of these defenses are discussed below, ad seriatim.
In the context of claim construction, "expressions such as 'substantially' are used in patent documents when warranted by the nature of the invention, in order to accommodate the minor variations that may be appropriate to secure the invention" and "indeed may be necessary in order to provide the inventor with the benefit of his invention." Verve LLC v. Crane Cams, Inc., 311 F.3d 1116, 1120 (Fed. Cir. 2002) [emphasis supplied]. "Words of approximation, such as 'generally' and 'substantially,' are descriptive terms commonly used in patent claims to avoid a strict numerical boundary to the specified parameter." Anchor Wall Sys. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1311 (Fed. Cir. 2003) (citations and internal quotation marks omitted).

Here, both parties submitted expert reports in support of their respective claim construction arguments, and Fisher-Price's expert also testified at the preliminary injunction hearing. With regard to the "contacting substantially all" limitation, Evenflo's expert, Dr. Mollendorf, states in his expert report that Evenflo's accused tray inserts "do not even contact 30% of the tray support surface" and therefore cannot be said to infringe claim 12. Def. Memo, p. 9; Mollendorf Decl., Ex. A, pp. 6, 12-13 ("the Evenflo tray insert rides on highpoints and ridges that comprise a small portion of the contacting support surface and that preclude substantial contact").

13 Dr. Mollendorf reached this conclusion by inserting paper strips between the insert and support trays of the accused products. He concluded that contact existed only in those areas where a strip of paper could not be fed between the tray's surfaces. He then computed the portion of the total possible contact area for each tray set at which contact actually occurs.

Fisher-Price counters that the general nature of this tray product is such that manufacturing tolerances for smoothness and fit cannot be expected to be particularly tight and further, that the drawings (e.g., '830 patent, Fig. 15) indicate that "contacting substantially all" does not necessarily mean surface-to-surface contact between the majority of points on the tray insert and support. What is important is that the tray insert "covers substantially all of the cavity." Pl. Reply, pp. 6-7; Col. 4, lines 17-18. Alternatively, Fisher-Price offered the expert testimony of Professor Visser, who identified irregularities in the lower surface of the Evenflo insert trays as pin marks created by the injection molding process. Tr. at 147:20-148:6. His opinion is that, assuming an unidentified number of these pin points are distributed in a way that provides support, the "contacting substantially all" limitation is met. Tr. 148:6-151:13.

In construing the phrase at issue here, "the question is not whether the word 'substantially' has a fixed meaning as applied to [the challenged term or phrase], but how the phrase would be understood by persons experienced in the field ... upon reading the patent documents." Verve LLC at 1119-20.

Upon reviewing the patent documents, the Court rejects Fisher-Price's contention that persons experienced in the field would view the terms "covering substantially all" and "contacting substantially all" as interchangeable. Under the doctrine of claim differentiation, "different claims are presumed to be different in scope." Inpro II Licensing S.A.R.L. v. T-Mobile USA, Inc., 450 F.3d 1350, 2006 U.S. App. LEXIS 11675, at *7 (Fed. Cir. May 11, 2006); see also, Intermatic Inc. v. Lamson & Sessions Co., 273 F.3d 1355, 1364 (Fed. Cir. 2001). Construing the claim term as Fisher-Price suggests would violate that doctrine.

Specifically, claim 20, which is also in dispute here, describes a tray kit. Two of its dependent claims, 23 and 25, use the terms "contacting substantially all" and "covering substantially all," respectively, to describe limitations on the interface between the insert tray and the support. Were one to replace the word "contacting" in claim 23 with "covering," as Fisher-Price suggests is appropriate, this Court is of the opinion that there would be no limitation in claim 25 not already present in claim 23.

Similarly, independent claims 12 and 27 both call for tray sets. Though both include some identical language and phrases, claim 12 employs the term "contacting substantially all" while claim 27 employs the term "covering substantially all." Compare, col. 6, lines 16-26 and col. 7, line 18 - col. 8, line 11. In this Court's view, upon reading the patent documents as a whole, persons experienced in the field at the time of the invention would view this as a conscious differentiation, rather than the same limitation described with different terminology.
Keeping in mind the Federal Circuit's characterization of the word "substantially" as one of approximation, this Court finds nevertheless that the term is commonly understood as meaning "largely" or "most"—i.e., at minimum, some figure greater than 50 percent. Even avoiding the imposition of a stringent numerical cutoff, this Court has no trouble rejecting Professor Visser's construction of "contacting substantially all" as meaning discrete points of contact distributed in such a way as to provide support. 14 The Court also finds unpersuasive Professor Visser's suggestion that, by the act of inserting paper strips between the Evenflo insert and base trays, it may be possible to lift the insert away from points of contact. Tr. 143:16-144:16. 15

--- Footnotes ---

14 Accepting Professor Visser's logic would again render meaningless the distinction between "contacting substantially all" and "covering substantially all"—e.g., an umbrella can cover substantially all of something it has little or no contact with.

15 Professor Visser took care in his discussion to state that he was speaking of this possibility generally and "didn't say that of [Mollendorf's] test."

--- End Footnotes ---

b. The construction of "substantially"

It is a convention of patent law that terms must be interpreted consistently in all their appearances in a patent. Fonar Corp. v. Johnson & Johnson, 821 F.2d 627 (Fed. Cir. 1987). Plaintiff contends that the term "substantially" must be interpreted to mean "essentially." Thus, in the first case, plaintiff would have this court interpret the above quoted phrase to mean that the gas pressure in the mold may be increased, decreased or held essentially constant. In the second case, plaintiff interprets the phrase "control means are operative to inject gas to fill out the mold cavity at a pressure that is at all times during the gas injection cycle substantially below the pressure of the stored gas supply", to mean that the pressure of the gas injected into the mold cavity is "essentially" below the pressure of the stored.

This reading of the term is incorrect. It appears to this court that the meaning of the second phrase quoted is changed considerably by this interpretation. Plaintiff's proposed interpretation does not comport with the commonly understood meaning of the word "substantially." Another convention of patent law holds that terms used in a patent claim should be understood to have their ordinary and common meaning unless the inventor specifically defines it to have some other meaning. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996).

The reading proposed by plaintiffs results in the term having almost no meaning in the second phrase. To read it in the manner asserted by plaintiffs results in the sentence having an almost nonsensical meaning.

It appears to the court that the inventor did not specify any meaning for "substantially", other than its common, ordinary meaning. Accordingly, the court must determine the proper meaning for the term "substantially" in the context of the 455 Patent. First, this court notes that it is a term of comparison. If it is to have any meaning, it must modify the term following in some way. This court finds the term to mean "to a considerable degree." In the case of the first phrase quoted above; the gas pressure is held substantially constant is held to mean "the gas pressure is held constant to a considerable degree." In the case of the second phrase, that stating that the pressure of the gas injected into the mold is substantially below that of the stored gas supply, it will be read to mean that the pressure of gas injected into the mold is below that of the stored gas supply to a considerable degree. This reading of the term appears to the court to come the closest to reconciling the two contexts in which the term substantially was used by the drafters of 455 Patent.

In an effort to forestall any future dispute about the meaning of "considerable", this court understands that term to mean large. This court does not attach specific values to the respective pressures, that in the supply of stored gas and the pressure of the gas injected into the mold. The court notes, however, that the drafters of the 455 Patent include examples of the pressures at which various elements of the claimed invention are to operate at several points in the specification of the 455 Patent. These values disclose pressure differences on the order of 6-11,000 psi, with the pressure of the stored gas supply...
always being the higher of the quoted pressures. Accordingly, the court finds that pressure differentials of 6-11,000 psi are "substantial" for purposes of the interpretation of the disputed claims of the 455 Patent, with the pressure of the gas injected into the mold always being the lower of the two values. The court believes that a pressure differential of, say, 8,000 psi would commonly be understood by one skilled in the art to be "substantial". This is not to be taken to mean that other pressure differentials could not be understood to be "substantial" for these purposes.

GO BACK

3853
B. "Substantially"

The district court construed the term "substantially" in the claimed phrase "substantially below" to mean "to a considerable degree," and further construed "considerable" to mean "large." The district court did not attach specific values to the pressures compared in the claims using the phrase "substantially below," but did find that pressure differentials between 6-11,000 psi, including 8,000 psi, are "substantial" for purposes of the 455 patent.

Epcon argues that the district court erroneously imputed a quantitative meaning to the phrase "substantially below." Epcon argues that the phrase should instead be interpreted to mean "essentially below." Bauer argues that the phrase was added to distinguish over the prior art during prosecution, and the district court's construction was correct.

The term "substantially" is used in claims 2 and 16 in two slightly different contexts, i.e., "substantially below," and "substantially constant." As noted by both parties, the same term or phrase should be interpreted consistently where it appears in claims of common ancestry. Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 980, 52 U.S.P.Q.2D (BNA) 1109, 1114 (Fed. Cir. 1999); Abtox, Inc. v. Extron Corp., 131 F.3d 1009, 1010, 46 U.S.P.Q.2D (BNA) 1735, 1735-36 (Fed. Cir. 1997); Fonar Corp. v. Johnson & Johnson, 821 F.2d 627, 632, 3 U.S.P.Q.2D (BNA) 1109, 1113 (Fed. Cir. 1987). However, this case implicates the more precise statement of the axiom, i.e., "[a] word or phrase used consistently throughout a claim should be interpreted consistently." Phonometrics, Inc. v. Northern Telecom Inc., 133 F.3d 1459, 1465, 45 U.S.P.Q.2D (BNA) 1421, 1426 (Fed. Cir. 1998) (emphasis added).

In this case, the term "substantially" was used in two contexts with a subtle but significant difference. The phrase "substantially constant" denotes language of approximation, while the phrase "substantially below" signifies language of magnitude, i.e., not insubstantial. Because the same term was used in a different manner in these two phrases, the word "substantially" should not necessarily be interpreted to have the same meaning in both phrases.

The district court correctly construed the phrase, "substantially below," in light of relevant portions of the prosecution history. The prosecution history shows that the phrase was added to the claims during prosecution to distinguish the claimed invention over the prior art Baxi reference. It is unclear that "substantially below," as opposed to merely "below," was required to distinguish the prior art. But in any event, Bauer is correct that this limitation was added to distinguish the prior art, and Epcon should be held to the phrase it chose. Also, Epcon's proposed construction "essentially below" would make little sense in context, where "essentially" could connote "above or below," and the prior art would appear to disallow such an interpretation. The district court did not err in construing the phrase "substantially below," as used in the context of the claims.

3854
3. Claim Construction of the Term "Substantially a Lumbar Region"

Both parties dispute the construction of the term "at substantially a lumbar region" as it is used in claim 1 of the '741 patent. The claim recite "each of said upper sections extends from one of said respective lower sections so as to form a pair of first bowed sections at substantially a lumbar region of said backrest . . . ." Id., col. 22, ll. 45-48 (emphasis added). Defendants argue that this limitation requires the bowed section to be at the lumbar region of the backrest, which is between six and ten inches above the seat of the chair. According to defendants, a person having ordinary skill in the art would recognize the lumbar region to be a specific region of the human spine, which the seating industry standards locate as being between six
and ten inches above the seat. Defendants further contend that the claim drafter's implementation of the term "substantially" mandates that a majority of the bowed section rest within the six to ten inch range. Defendants base this argument on their belief that when the term "substantially" modifies a location or position, it is language of magnitude.

In contrast, plaintiff argues that the specification and claims make clear the term "at substantially a lumbar region" means the portion of the backrest that supports the lumbar region of a user's spine. In particular, plaintiff contends that defendants are reading an industry standard into the claims which, according to plaintiff, is both improper and unnecessary because the intrinsic evidence provides enough insight into the meaning of the term. Further, plaintiff asserts that the term "substantially" is a term of approximation--at least as used in the claim--and that defendants are incorrect in understanding "substantially" to require the bowed sections to be "mostly in, or within" the lumbar region. Rather, plaintiff argues, the term means "at or near" and as a result, the first bowed sections are located at or near a region of the backrest that will support the lumbar region of a user's spine.

The court agrees with plaintiff's construction. The language of the claims--in light of the specification--provides the proper construction of "at substantially a lumbar region of said backrest," which is approximately the portion of the backrest where the lumbar section of a user's back would be supported by the backrest. The specification simply calls for the first and second bowed sections to act in unison "[t]o support the lumbar region of a user's back . . . ." Id., col. 12, ll. 65-67. The court finds it unnecessary to resort to industry standards to define what the term "lumbar region" means. The term is not indefinite because one of ordinary skill in the art would readily understand the meaning of "lumbar region."

Moreover, even if the court were to entertain defendants' insistence on using the standard to illuminate the meaning of the claim term, the court notes that the standard was misinterpreted by defendants. Defendants cite an industry standard--one from the American National Standards Institute ("ANSI")--to define what exactly the "lumbar region" is. The Federal Circuit has acknowledged that "regulations issued by regulatory agencies can be helpful to a claim construction analysis if they are probative of an industry-specific meaning for a disputed claim term." Mars, Inc. v. H.J. Heinz Co., L.P., 377 F.3d 1369, 1374 n.3 (Fed. Cir. 2004). Defendants argue that the standard demands that the lumbar region be 6.0 to 10.0 inches above the seat. This interpretation of the standard, however, is incorrect. The industry standard cited states:

Current practices and information suggest that, for upright or near-upright posture chairs, a lumbar support area of at least 15.2 to 22.9 cm (6.0 to 9.0 inches) high and 30.5 cm (12.0 inches) wide with a vertically convex and horizontally concave radius is acceptable (Farrell and Booth, 1984). A vertical height to the center of the lumbar support, either fixed or adjustable, within the range of 15.2 to 25.4 cm (6.0 to 10.0 inches) above the Seat Reference Point (SRP) is generally acceptable (Branton, 1984).

First, the use of the terms "suggest" and "acceptable" indicate that the standard falls within the species of a guideline rather than a hard and fast rule. Second, defendants have misread the terms of this standard. It does not require a four inch high range for the lumbar region. Rather, as plaintiff correctly points out, the suggested height-range, or span, of the lumbar support region is 6.0 to 9.0 inches. As a result, because the standard suggests that the vertical height to the center of this support region--as measured from the seat--should be within the range of 6.0 to 10.0 inches, the lumbar support region can begin with the bottom portion of the region at 1.5 inches above the seat and extend to where the top portion of the support region is at 14.5 inches above the seat (depending on whether one is using the 6.0 inch height range or the 9.0 inch height range). Therefore, the suggested lumbar region is much larger in area than that urged by defendants.

Again, however, the standard is not dispositive of the claim construction, because without it one of ordinary skill would nonetheless readily understand the meaning of the term. ANSI standards were only briefly recited in the Background of the Invention section of the specification, to provide background information relating to seat height--not lumbar region ranges.

Furthermore, this court agrees with plaintiff's interpretation of the term "substantially" as used in the claims. "Expressions such as 'substantially' are used in patent documents when warranted by the nature of the invention, in order to accommodate the minor variations that may be appropriate to secure the invention." Verve v. Crane Cams, Inc., 311 F.3d 1116, 1120 (Fed. Cir. 2002). Further, "like the term 'about,' the term 'substantially' is a descriptive term commonly used in patent claims to 'avoid a strict numerical boundary to the specified parameter.'" Ecolab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1367 (Fed. Cir. 2002).
A plain reading of the claims compels the court to interpret "substantially" to mean "approximately" or "about" as opposed to a term of magnitude. The straightforward language of the claim itself provides support for this conclusion. The claim recites in relevant part, "so as to form a pair of first bowed sections at substantially a lumbar region of said backrest." '741 Patent, col. 22, ll. 46-48. The claim tells a person having skill in the art where the bow is formed at; it is expressing that the bowed-shaped section is formed not "perfectly" or "precisely" at the portion of the backrest where the lumbar region of the user will be located, but rather, at "substantially," or in other words "approximately" the portion of the backrest where the lumbar region of the user will be located. See Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 442 F.3d 1322, 1329 (Fed. Cir. 2006) ("The term 'substantial' implies 'approximate,' rather than 'perfect'.").

The court notes that the term "substantially" appears numerous times throughout the specification--albeit not when describing the bowed-shaped section. For instance, in the Summary of the Invention, the patentee states "the linkage assembly is adapted to allow the seat and back to tilt downwardly and rearwardly such that the seat pivots about an effective pivot point at substantially the ankle of a user having feet resting on a floor." '741 Patent, col. 2, 58-62 (emphasis added). In another portion of the Summary of the Invention, the patentee again uses the term, stating "The piston rod is extensible [sic] between a collapsed position in which the cylinder and inner tube are substantially within the intermediate tube and the intermediate tube is substantially within the outer guide tube . . ." Id., col. 3, ll. 7-12 (emphasis added).

If the patentee had desired to convey to persons having skill in the art that the bulk of the bowed section be located within the lumbar region of the backrest, he certainly could have done so by adopting the phrase "substantially within" as he did in the Summary of the Invention when discussing the piston rod. As the claim currently stands, however, the court declines to engage in the type of word stretching needed to bend the term "substantially" around defendants' asserted construction. Therefore, the court finds the term "substantially" to mean "approximately" or "about." Thus, the term "at substantially a lumbar region" means approximately the portion of the backrest where the lumbar section of a user's back would be supported by the backrest.

D. Claim 1(e) - "At Substantially a Right Angle"

Claim 1(e) provides that the handle grip must include

a graspable arm attached to the outer end of said handle grip and extending generally laterally upwardly in a direction away from the floor when in use and at substantially a right angle with respect to the longitudinal axis of said handle during use and being graspable by the hand of a standing operator.

'315 Patent at 4:33-38. Dyson asserts that this limitation requires that the graspable arm of the device be at an angle at or near 90 degrees to the longitudinal axis of the handle. See Joint Claim Constr. Statement at A-2. Oreck proposes a functional construction and states that "a substantial right angle will exist where the graspable arm is above the handle and the user can grasp it in such a way that he or she will have a strong wrist position, that is, one in which the forearm, hand, and fingers are aligned in a strong position." Id.

It is beyond dispute that the plain and ordinary meaning of the term "right angle" is an angle of 90 degrees. The term "right angle" in claim 1(e) is modified, however, by the term "substantially." In the context in which it is employed here, "substantially" is a term of approximation. See Anchor Wall Sys., 340 F.3d at 1310-11; Cordis Corp. v. Medtronic AVE, Inc., 339 F.3d 1352, 1360 (Fed. Cir. 2003); see also Deering, 347 F.3d at 1323 (noting that "substantially" can be either a term of approximation or a term of magnitude). Terms of approximation such as "substantially" are frequently included in patent claims and are generally used to "avoid a strict numerical boundary to the specified parameter." Ecolab, Inc. v.
Envirochem, Inc., 264 F.3d 1358, 1367 (Fed. Cir. 2001) (quoting Pall Corp. v. Micron Separations, Inc., 66 F.3d 1211, 1217 (Fed. Cir. 1995)); Playtex, 400 F.3d at 907 (noting that "substantial" should not be interpreted to incorporate a "strict numerical limitation"); see also Verve, LLC v. Crane Cams, Inc., 311 F.3d 1116, 1120 (Fed. Cir. 2002) ("Expressions such as 'substantially' are used in patent documents . . . in order to accommodate the minor variations that may be appropriate to secure the invention."). Thus, the phrase "at substantially a right angle" in claim 1(e) should be construed to mean that the graspable arm of the handle grip must extend at an angle of at or near 90 degrees to the longitudinal axis of the handle. See Cordis, 339 F.3d at 1360 ("substantially uniform thickness" interpreted to mean "of largely or approximately uniform thickness"); York Prods., Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1573 (Fed. Cir. 1996) ("substantial part of the entire height" construed to mean "nearly the entire height"); AmhIl Enters. Ltd. v. Wawa, Inc., 81 F.3d 1554, 1562 (Fed. Cir. 1996) ("substantially vertical" construed to permit deviation "only slightly, if at all, from the vertical").

Oreck interprets the phrase "at substantially a right angle" as a wholly functional limitation that can be defined only by reference to the "strong wrist position" of the user while he or she operates the device. This construction fails for at least two reasons. First, the requirement that the graspable arm extend "at substantially a right angle" is a clear structural limitation on the claim. Oreck's proposed construction would impermissibly read this structural limitation out of the claim and render the claim language essentially meaningless. See K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1363 (Fed. Cir. 1999) (rejecting functional interpretation that would "effectively expunge" specific claim limitation); York Prods., 99 F.3d at 1573 (rejecting functional argument when "the claim language explicitly ties 'substantial part' to the height of the sidewalls, not to the overall function of the invention"). Second, claim 1(f) already contains the limitation that the graspable arm be such that it "provide a strong wrist position for the operator." '315 Patent at 4:46-47. It would make little sense to redefine an unambiguous structural limitation to simply duplicate a functional limitation that also appears in the claim language. See K-2, 191 F.3d at 1363.

Oreck also argues that the graspable arm need not extend its entire length "at substantially a right angle," but rather that only some initial portion of the arm must be at a substantially a right angle to the longitudinal axis of the handle. Oreck argues that a construction of claim 1(e) that required that the graspable arm extend its full length at an angle at or near 90 degrees would exclude claim 7, which describes a cleaner with a graspable arm that "curves forwardly slightly" toward the base unit as it proceeds away from the longitudinal axis of the handle. '315 Patent at 6:3-6.

Dyson responds that Oreck's proposed construction would effectively read the "at substantially a right angle" limitation out of claim 1(e), because it would permit the limitation to be satisfied by a device in which only some tiny fraction of the graspable arm is at or near a 90-degree angle to the elongated handle.

The Court is not persuaded that only the initial portion of the arm must be at or near a 90-degree angle to the longitudinal axis of the handle. First, nothing intrinsic to the claim language compels Oreck's proposed construction, and if the inventors had intended to require only that the graspable arm initially extend, or begin to extend, at substantially a right angle to the handle, they certainly could have included such language in the patent claims. But they did not. Instead, claim 1(e) simply requires "a graspable arm . . . extending . . . at substantially a right angle with respect to the longitudinal axis" of the handle, which would appear to contemplate, at the very least, that the "graspable" portion of the arm be at or near a 90-degree angle to the elongated handle.

This construction is confirmed when claims 1(e) and 1(f) are read together. Claim 1(e) describes the orientation of the graspable arm in relation to the elongated handle. It requires that the graspable arm extend "generally laterally upwardly" from the handle. '315 Patent at 4:35. This otherwise vaguely-defined limitation is narrowed and made precise by the language that immediately follows it. That language, which was added to claim 1(e) as part of an examiner's amendment shortly before the '315 patent was approved, 5 clarifies that the graspable arm must extend "in a direction away from the floor when in use and at substantially a right angle with respect to the longitudinal axis of [the elongated] handle." '315 Patent at 4:35-38. Claim 1(f) then describes the distance for which the graspable arm must extend from the handle in this generally lateral upward direction. It states that the graspable arm must be "sufficiently long in a direction generally laterally and upwardly away from said handle so that it will accommodate the width of a user's hand grasping said arm." Id. at 4:40-43. Read together, these requirements establish two, complementary limitations: (i) that the graspable arm must extend from the elongated handle in a specific direction (i.e., "away from the floor when in use and at substantially a right angle with respect to the longitudinal axis of [the elongated] handle"); and (ii) that it must do so for at least a specified distance (i.e., "sufficiently long . . . that it will accommodate the width of a user's hand grasping said arm").
5 See Brebner Decl. Ex. BB(21).

6 The slight difference in phrasing ("generally laterally upwardly" in claim 1(e), and "generally laterally and upwardly" in claim 1(f)) does not alter this construction. In this context, a person of reasonable skill in the art would interpret the phrase "generally laterally and upwardly" in claim 1(f) in light of the specific narrowing language that applies to "generally laterally upwardly" in the immediately preceding claim 1(e).

Nor is Oreck's proposed construction necessary to give meaning to claim 7, which permits the graspable arm to "curve[] forwardly slightly towards said base unit as it proceeds upwardly away from said longitudinal axis of said handle." '315 Patent at 6:4-6. Oreck's argument incorrectly assumes that there is some fundamental inconsistency between a graspable arm that curves "slightly," i.e., a small amount, 7 and one that extends "at or near" a right angle. There is not. An object can both curve slightly and still be at or near a 90-degree angle relative to another object.

Accordingly, the Court finds that the graspable arm of a device that meets the limitations of the ‘315 patent must be at or near a 90-degree angle with respect to the longitudinal axis of the cleaner's elongated handle for a distance sufficient to accommodate the width of a user's hand.

Finally, Oreck argues that, based on the figures depicted in the patent documents, the phrase "at substantially a right angle" must be construed to include, at a minimum, all angles between 60 degrees and 110 degrees. To arrive at these numbers, Oreck points to figure 2 of the ‘315 patent, which portrays a graspable arm that "is bowed or curved from its point of anchorage with the first grip portion to its opposite end." '315 Patent at 1:62-64. Oreck has measured the angles relative to the longitudinal axis of the handle created by tangents to the curved outer surface of the graspable arm at its near and far ends, and it calculates those angles to be 110 degrees and 60 degrees, respectively. See Fig. 3 (Aghazadeh Aff. Ex. B). Oreck then asserts, invoking the principle that claim limitations should not be construed in a way that would exclude the depicted embodiment of the invention, that these angles necessarily constitute "substantially" right angles within the meaning of claim 1(e). Oreck further asserts that it is appropriate to measure the angle of the graspable arm by reference to the outer edge of the arm because the angle at which a user grasps the arm is dictated by the angle of the arm's outer edge. See Oreck Supp. Mem. at 7 n.7.

This argument misses the mark. First, the language of claim 1(e) requires only that the "graspable arm" extend outward from the longitudinal axis of the handle "at substantially a right angle." ‘315 Patent at 4:33-37. The claim makes no reference to whether the outer edge of the arm is straight, bowed or otherwise. The most natural reading of claim 1(e) is that the limitation should be read with reference to the angle of the arm itself, and not its edges, at the point or points at which it is likely to be grasped by a user's hand. In any event, even were it appropriate to measure the angle of the graspable arm with reference to its outside edge, Oreck's proffered measurements would still be irrelevant to the proper construction of the claim. The 60-degree and 110-degree angles that Oreck refers to are measured from points at the ends of the graspable arm depicted in figure 2, points at which it is unlikely that a user would actually grasp the arm.
4. What is the Proper Construction for the Phrase "substantially above the softening temperature" in the '311 Patent?

Claims 1 and 94 of the '311 patent contain the phrase: "substantially above the softening temperature of said binder material but to a temperature less than the softening temperature of said primary material." KXI contends that the phrase "substantially above . . ." means the temperature is sufficiently above the softening temperature of the binder to allow conversion of the binder to a continuous web matrix or forced point-bonds. KXI contends no specific temperature is required. Culligan contends the phrase "substantially above . . ." means the temperature exceeds the binder's softening temperature by at least approximately 20 degrees Celsius.

KXI argues that this phrase is similar in meaning to the same phrase used in the '092 and '948 patents. KXI argues that the plain meaning of the words defines the meaning of the claims. According to KXI, no specific temperature is required under the claims, and setting out such a requirement would not even be feasible because the temperature needed to convert the binder varies based upon the size and shape of the object being produced and the binder selected. KXI cites in support column 14, lines 56-59 of the '311 patent. This reads in relevant part: "The process disclosed in the Degen '683 patent and distinguishes it from the present invention. The passage reads in relevant part:

Degen et al. . . . describes a process using a temperature of approximately 275 degrees F (135 degrees C), which is generally below the temperatures required in the subject invention to achieve the desired novel structures. Formation of a novel continuous polymer phase or forced point-bonding, according to the present invention, even with the lowest melting point resin available, ethylene-vinyl acetate copolymer (EVA), usually occurs at 145 degrees Celsius . . . and is optimal in the range of 165-210 degrees Celsius. The temperatures required by the process of the subject invention are therefore substantially higher than required for diffusion bonding processes such as that described by Degen et al., even for the binder resin having the lowest melting point. Degen et al. teach the use of temperatures only sufficient to produce a softening of the binder because they are seeking a point bond and are not seeking a more dramatic conversion of the thermoplastic binder into a different physical form. (Emphasis added).

Culligan also argues that the patentee disclaimed processing temperatures used in the Degen '683 patent in distinguishing it. Culligan cites the '311 patent's specification at column 2, line 52 to column 3, line 2. This passage describes the prior art process disclosed in the Degen '683 patent and distinguishes it from the present invention. The passage reads in relevant part:

Culligan contends the manufacturer's specification sheet specifies that the EVA binder used in the Degen '683 process (532 EVA) has a softening temperature of approximately 75 degrees Celsius and a melting point of approximately 96 degrees Celsius. U.S. Patent No. 4,664,683, col. 6, lines 31-34; col. 14, line 66 to col. 15, line 1. The Degen '683 patent uses a processing temperature of 135 degrees Celsius, which is 60 degrees Celsius higher than the softening point of the 532 EVA binder. The '311 patent distinguishes the Degen '683 patent's prior art based upon the temperatures required for the respective processes. The '311 patent characterized the temperatures disclosed by the Degen '683 patent as "generally below" the temperatures needed to produce the "continuous web matrix" and "forced point-bonding" structures disclosed in the '311 patent.

Culligan also cites examples 17 and 18 from the '311 patent's specification. These examples disclose that pellets produced by compression molding mixtures of stainless steel powder, 532 EVA binder and powdered ion exchange resin crumbled when heated to temperatures at and below 170 degrees Celsius, which is 95 degrees Celsius above the 532 EVA's softening temperature. Culligan also cites a passage from the '311 patent's specification characterizing temperatures necessary to process activated carbon and 532 EVA as 190 to 210 degrees Celsius, or 125 to 155 degrees Celsius above the 532 EVA binder's softening temperature. KXI argues in response that the Degen '683 patent talks about process temperature, and not the mixture temperature, and that example 17 of the '311 patent talks about the mold's temperature.

The court agrees with KXI that the temperature needed to convert the binder varies based upon the size and shape of the
object being produced and the binder selected. Accordingly, the court construes the phrase "substantially above the softening temperature" to mean sufficiently above the softening temperature of the binder to allow conversion of the binder to a continuous web matrix or forced point-bonds.

6. What is the Proper Construction for the Phrase "substantially above the softening temperature of said binder material" in the '092 and '948 Patents?

Claim 1 of the '092 patent includes the phrase "heating said substantially uniform mixture within said die to a temperature substantially above the softening temperature of said binder material . . . ." Claim 1 of the '948 patent includes the phrase "means in said die adjacent to the inlet end thereof for heating said particulate mixture within said die cavity to a temperature substantially above the softening temperature of said binder material . . . ." KXI contends the phrase "substantially above" means the minimum heat required by the claims. This is a temperature which is sufficiently high both to form a composite and to keep the mixture from solidifying in the extruder. Culligan contends the phrase "substantially above" means that the temperature exceeds the softening temperature of the binder by approximately 25 degrees Celsius.

Culligan relies on statements in the specifications of the '092 and '948 patents that the heat applied to the mixture be "generally about 25 degrees Celsius above" the softening temperature of the binder. See U.S. Patent No. 5,189,092, column 2, lines 12-15; '092 patent, column 9, lines 9-10; U.S. Patent No. 5,249,948, column 2, lines 16-19. KXI argues that "generally about 25 degrees Celsius above" the softening temperature of the binder is a preferred example, but does not define the term "substantially above." According to KXI, the specification sections relied on by Culligan are "neither attempts to define the claim terms nor are they expressed as requirements in order to practice the claimed invention." Therefore, KXI argues, the court should not read them as defining the claim.

KXI argues that Culligan's interpretation violates the doctrine of claim differentiation with respect to the '092 patent. Claim 5 of the '092 patent, which is dependent upon claim 1, includes the limitation "at least about 25 degrees Celsius above the softening temperature of said binder material."

KXI also argues that a set temperature increase would fail to account for the variety of different binders that may be used, each of which may have different temperature requirements. According to KXI, the specifications set out an operating window within which the temperature must fall. This operating window necessarily varies based upon the specific binder material used. The parameters are set by column 5, lines 31-36 of the '092 patent, and column 5, lines 37-41 of the '948 patent. These passages read: "There is a minimum heat and a maximum heat--if a substance is heated insufficiently, it will not solidify and will be very prone to 'locking' within the extruder die. If overheated, it will have a strong tendency to lock up within the die." According to KXI, defining the phrase "substantially above" to mean 25 degree Celsius is contrary to the teaching of the invention that the parameter for the heating temperature be set according to the qualities of the binder used.

KXI recognizes that the "minimum heat and . . . maximum heat" requirement is "intended to teach that there is a limited range of temperatures that can be used in plaintiff's process." But, KXI argues, this requirement does not provide a definition of "substantially above" as used in both claims.

Claim 5 of the '092 patent is dependent upon claim 1. If the court were to construe "substantially above" to mean the temperature exceeds the softening temperature of the binder by approximately 25 degrees Celsius, claim 5 would be superfluous. See, e.g., Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987) ("To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant.") The court notes "there is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims." Id.

The specification has stated that "substantially above" is "generally at least about 25 degrees Celsius" and is "preferably at least about 25 degrees Celsius above the softening point of the binder. . . ." The court finds, however, the specification does not define the term "substantially above" to mean "about 25 degrees Celsius." The court finds a lower temperature difference might satisfy the "minimum heat and . . . maximum heat" requirement, depending upon the binder used. Accordingly, the court construes the phrase "substantially above" to mean a temperature which is sufficiently high both to
form a composite and to keep the mixture from solidifying in the extruder.

2. "substantially all"

Claim 1 requires that "substantially all of said bolster [be] disposed exteriorly about at least a portion of the perimeter of the bottom portion." 502 patent at col. 3, ll. 43-44 (emphasis added). The parties appear to agree that this means that some of the bolster is located along the perimeter, as opposed to the top, of the bottom cushion. The dispute centers around exactly how much of the bolster must be alongside the bottom cushion in order to satisfy the "substantially all" limitation. Defendants argue that "substantially all" should be construed as "largely, but not wholly, the totality of the bolster." Flexi-Mat argues that the amount should not be expressly quantified, but that the entire bolster is not required to be located alongside the perimeter.

The term "substantially all" in this context is neither technical nor complex. If the term "all" were unmodified, the entirety of the bolster would rest alongside the perimeter of the bottom cushion, and no part of it could lie on top of the cushion. See Webster's Third New International Dictionary (1986) (defining "all" as "the whole amount or quantity of"). The adjective "substantially" suggests that not just a small portion, but some significant amount, of the bolster must be located along the perimeter of the bottom cushion. See id. (defining "substantial" as "of or relating to the main part of something").

This language is simple and clear, and according to Phillips, 415 F.3d at 1313, I need go no further than applying the widely accepted meaning of these commonly used words. Nevertheless, I note that the drawings in the specification and the prosecution history support the construction of "substantially all" as requiring the main portion of the bolster to be positioned along the outside edge of the bottom cushion.

Figures 1-5 each depict a circular base cushion with a semi-circular bolster positioned around its perimeter. The edge of the bolster appears to rest slightly on top of the bottom cushion, and in Figure 2, a small portion of the bolster seems to touch the ground. But the main portion of the bolster is clearly located along the outside edge of the bottom cushion. The remainder of the written description is not clear as to what portion of the bolster must be located along the edge of the bottom cushion. The specification states that the bolster is "disposed about at least a portion of the perimeter of the cushioned bottom portion of the pet bed," but offers no further detail. 502 patent at col. 2, ll. 52-54.

The prosecution history sheds some light on the question. At the recommendation of the examiner, the patentee added the words "substantially all of said bolster" and "exteriorly" to distinguish the position of the bolster over the Henry patent. The Henry patent primarily described top cushions that rested entirely on top of the bottom cushion, but it explicitly identified an alternative embodiment in which the top cushions extend beyond the edges of the base cushion. 843 patent at col. 3, ll. 18-19. To avoid anticipation by Henry, the patentee made clear that the bolster in the 502 pet bed was not situated primarily on top of the bottom cushion, but along its outside edge.

I agree with Flexi-Mat that expressly quantifying a percentage of the bolster that must be located along the outside edge of the bottom cushion is unnecessary. However, merely stating that the entire bolster need not be exterior ignores the modifier "substantially." In contrast, Defendant's proposed definition -- "largely, but not wholly, the totality of the bolster" -- accurately reflects the requirement that a main part of the bolster be disposed exteriorly while allowing for a small portion of the bolster to make contact with the floor or the top of the cushion. Thus, I construe "substantially all" to mean "largely, but not wholly, the totality of the bolster."

G. "substantially all light"

This term describes how much of the light that hits the coating is reflected. The parties offer differing constructions. The Defendants propose to substitute the phrase "essentially all light"; Nichols proposes to substitute "a large portion of but not
all of the light which falls on the body of the lure."

The Court concludes that the term is not ambiguous, thus the ordinary meaning should prevail. The ordinary meaning of the term is "all but an insignificant amount." Atmel Corp. v. Information Storage Devices, Inc., 997 F. Supp. 1210, 1229 (N.D.Cal. 1998), rev'd on other grounds by 198 F.3d 1374 (Fed. Cir. 1999).

3860

3. A display covering "substantially all of said panel."

The claim limitations "panel" and "substantially all of said panel" appear in claims 1 and 16 of the '845 patent and claim 11 of the '478 patent. All the claims require that the claimed device have a "panel." The "substantially all" language describes the relationship between different claim elements and the panel. Claim 1 of the '845 patent and claim 11 of the '478 patent both require that the display elements are small enough to enable the user instructions and key information to be presented over "substantially all of said panel." Claim 16 of the '845 patent requires the displaying means and data entering means to be in an overlapping relationship with the panel and to extend over "substantially all of said panel."

Palm argues that it also does not infringe claims 1 and 16 of the '845 patent and claim 11 of the '478 patent, because Palm's handheld computers do not include a display covering "substantially all of said panel." This position is based on Palm's proposed definition for the "panel" as meaning "the entire face or upper surface of the device, i.e., the face or surface where the controls are located." In opposition, NCR contends that the term panel should be defined as a smaller area, "that portion of the surface of the claimed device which functions as both a display and a keyboard," and should not be defined as encompassing the entire surface of the claimed device.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

11 The court focuses its analysis on the dispute as to the construction of "panel" and not on the dispute regarding "substantially all." Palm urges the court to place a percentage value (more than x percent) on "substantially all." The court declines this invitation. "Substantially all of the said panel" simply means "largely or essentially all" of the panel. Resolving the dispute about what constitutes the "panel" will be determinative in resolving the parties' dispute about this claim limitation.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

As both parties reference Fig. 3 of the Hale patents (identifying "panel 24" and "display 26") to support their claim construction argument, the court will reproduce that figure below: FIG. 3

[SEE FIGURE IN ORIGINAL]

a. Palm's Position

Palm draws support for its proposed construction from the ordinary meaning of the term "panel" and from the specification of the patents.

First, it notes that the ordinary meaning of "panel" is the face or surface where the controls are located, as evidenced by both technical and general purpose dictionary definitions. The McGraw-Hill Dictionary of Science and Engineering (1984) defines the term "panel" as "the face of the console, which is normally equipped with lights, switches, and buttons to control the machine . . . ." or as "a metallic or nonmetallic sheet on which operating controls and dials of an electronic unit or other equipment are mounted." McGraw-Hill Dictionary of Science and Engineering 690, 691 (1984). Webster's New Universal Unabridged Dictionary (2d. ed. 1983) defines "panel" as "an insulated board, or flat surface, for instruments or controls . . . ." Webster's New Universal Unabridged Dictionary 1293 (2d. ed. 1983).

Palm goes on to argue that, consistent with this ordinary meaning, the patent specification uses the term "panel" to refer to the entire face or upper surface of the device, "top panel 24," which is where the controls -- the plurality of switches 30 --
are located. Col. 5, II. 50-57; col. 5, II. 36-43. Moreover, it notes that Figs. 3-6 of the patents identify the "top panel 24" as the entire face or upper surface of P Terminal 12. The arrow for the "panel 24" is drawn to indicate the entire face of the device, including the display 26 and the area where the transmitting area 20 and sensor 22 are located.

Last, Palm argues that under NCR's definition, "panel" is synonymous with "display." Palm asserts that this "would lead to the self-fulfilling and nonsensical construction that the display covers substantially all of the display." Palm asserts this definition is improper because the reference arrow on Figs. 3-6 makes clear that the "panel 24" covers the entire face of the P Terminal, including the display 26 and the optical coupling area.

For these reasons, Palm contends that the term panel refers to the entire face or upper surface of the device.

b. NCR's Position

NCR asserts that a thorough review of the specification indicates that Palm's definition of "panel" as "the entire face or upper surface of the device" is not consistent with the manner in which the term "panel" is used in the specification or the claims of the Hale patents. See Vitronics, 90 F.3d at 1584 n.6 ("Judges . . . may rely on dictionary definitions when construing claim terms, so long as the dictionary definition does not contradict any definition found in or ascertained by a reading of the patent documents."). NCR contends that the specification clearly shows that the "panel" occupies less space than the entire surface of the claimed device.

First, NCR points out that the specification makes clear that the hard frame of the device is not included in the definition of panel. Instead, the specification refers to the "panel" as "a semi-flexible top panel 24 which functions as both a display and a keyboard." '845 patent, col. 4, II. 19-21. The specification goes on to state that:

when viewing the top panel 24 as a display, there are display elements or pixels which are distributed over the panel 24 in a pattern that is appropriate to display information to the user. The panel can be viewed as having nine line displays 26-1 through 26-9 which will be collectively referred to as display 26.

Id., col. 4, II. 21-26. Under Palm's definition of "panel," which includes the hard frame itself, that portion of the panel cannot function as a display or a keyboard.

Second, the specification also makes clear that the panel, which functions as a display and keyboard, is distinct from and does not include the frame on the front surface of the handheld device, e.g., the Bezel frame 48 shown in Figs. 3 and 7. See Id., Fig. 3, Fig. 7, col. 6, II. 17-18. The specification explains that the frame retains the display elements and the plurality of switches (the data entry mechanism) in the upper compartment. Id., col. 6, II. 8-24. This language clearly limits the panel to that portion of the surface of the device that functions as both a display and a keyboard and excludes the portion of the surface of the device covered by the Bezel frame in the preferred embodiment.

NCR argues that this is further confirmed by reference to the claim language. In both claims 12 and 16, the language used in connection with the "substantially all" limitation does not concern the frame of the device, but is directed expressly at the display and keyboard section of the device. Claim 12 states that "the plurality of discrete switches . . . [must be] arranged in a matrix of switches which . . . extends over substantially all of said panel." Similarly, claim 16 requires the "said displaying means and said entering means" to be in "overlapping relationship relative to said panel and extending over substantially all of said panel."

As for Palm's argument that the arrows on Fig. 3-6 delineate the entire surface as the "panel," NCR contends that Palm reads too much into the arrows on the Figure. NCR contends that, when viewed in accordance with patent drafting rules for the use of arrows and lead lines in figures, it becomes clear that the arrow labeled "panel 24" is not pointing to the entire surface of the device, but is only pointing to that portion of the device that functions as a display and keyboard. The patent drafting rules indicate that arrows are to be used as opposed to lead lines -- when the location of the structure is indicated, but not touched. See MPEP § 608.02 ("Lead lines . . . extend to the feature indicated." "Arrows . . . indicate the entire section towards which it points"). NCR argues that if "panel 24" were pointing to the surface of the device (including the frame), a lead line would have been used.

Last, NCR argues that it is not, as Palm asserts, equating the "panel" with the "display." Under NCR's definition, the panel
simply overlays the display. As the specification describes the various elements as overlaying each other, such a definition is wholly consistent with the Hale patents. This is demonstrated by Fig. 7 of the Hale patents, which is "an exploded view, in perspective, of the components of the terminal shown in Fig. 1." '845 patent, col. 2, ll. 31-32. The Bezel frame 48 is not shown in that drawing, but NCR contends that reference to Fig. 3 confirms that its would be placed over the top layer shown on the Fig. 7. Under that, lies the plurality of switches and the display elements, which are covered with a "top, transparent, flexible, plastic-film layer 50 such as Mylar . . . ". The specification adds that "the top transparent layer 50 (Fig. 7) protects the areas 20 and 22. '845 patent, col. 10, ll. 57-62. This, NCR argues, and not Bezel frame 48, comprises the claimed "panel" that the display elements are to extend to cover "substantially all of."

--- Footnotes ---

12 The "overlapping relationship" between the display and the panel is also confirmed by the language of claim 16 of the '845 patent and claim 6 of the '478 patent.

--- End Footnotes ---

To illustrate NCR's argument, the court reproduces Fig. 7 and an altered version of Fig. 7 with the Bezel frame 48 overlaying the device below.

Figure 7

[SEE FIGURE IN ORIGINAL]
Figure 7 with Bezel Frame 48 Shown

[SEE FIGURE IN ORIGINAL]

c. The Court's Construction

The court finds NCR's position to be more persuasive and will adopt its proposed construction of the term "panel." The claim language and specification, including the cited Figures, indicate that the panel occupies a portion of the surface of the claimed device and that it is the semi-flexible part of the transparent terminal which overlaps the display elements and the switches so that the terminal functions as a display and a keyboard. Palm's construction would encompass even the plastic frame, which cannot function as a keyboard and display.

Further, the court does not agree that the arrow pointing to "display 24" on Fig. 3-6 includes the frame of the device. Rather, the panel is simply indicated as the viewable area of the device. As the specification makes clear that the display, data entry, and panel elements are arranged in a layered fashion, it is more instructive to look to Fig. 7. In light of Fig. 7, the court does not believe that NCR's definition simply equates the "panel" with the "display area," instead the panel overlays the display area. Figs. 3-6 show a flat view of the device, where the Bezel frame 48 has been placed over the rest of the components identified in Fig. 7. This frame is not a part of the panel; it is laid over the panel.

NCR's proposed construction best comports with the specification, claims, and figures of the Hale patents. Accordingly, the court accepts NCR's proposed construction and construes "panel" to mean "that portion of the surface of the claimed device which functions as both a display and a keyboard."

GO BACK

Disputed Claim Language

Substantially all of said reactants remaining in said reaction space and adsorbed on inner walls of said reaction space are removed to a level of less than 1% prior to the inflow of a second pulse

ASM's construction

The gas volume of the reaction space containing reactive gas, as well as the unreacted reactants adsorbed on the inner walls of the reactant space, are removed essentially entirely between two successive vapor-phase pulses,
that is, to a level of less than one percent, so that reactant pulses of different starting materials remain isolated from each other and no substantial mixing of the reactants can occur within the reaction space, thereby substantially avoiding conventional CVD reactions within the reaction space.

Disputed Claim Language
Substantially all of said reactants remaining in said reaction space and adsorbed on inner walls of said reaction space are removed to a level of less than 1% prior to the inflow of a second pulse.

Genus has not proposed a claim construction of this claim language, instead arguing that the Court should find it indefinite as a matter of law and thus invalid under 35 U.S.C. § 112 P 2. ASM argues that invalidity is a separate issue from claim construction and thus the Court should defer a finding on invalidity for indefiniteness until a later date.

"The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention." 35 U.S.C. § 112 P2. The definiteness requirement of 35 U.S.C. § 112 P 2 "is essentially a requirement for precision and definiteness of claim language." PPG Industries, Inc. v. Guardian Industries Corp., 75 F.3d 1558, 1562 (Fed. Cir. 1996) (quoting In re Borkowski, 57 C.C.P.A. 946, 422 F.2d 904, 909 (C.C.P.A. 1970)). The language of the claims must make it clear what subject matter they encompass. Id. (quoting In re Hammack, 57 C.C.P.A. 1225, 427 F.2d 1378, 1382 (C.C.P.A. 1970)). Indefiniteness is a matter of law. Personalized Media Communications v. International Trade Commission, 161 F.3d 696, 702 (Fed. Cir. 1998). Determining whether a claim is definite requires an analysis of whether a person of ordinary skill in the art would understand the bounds of the claim when read in light of the specification. Id. at 705 (quoting Miles Lab., Inc. v. Shandon, Inc., 997 F.2d 870, 875 (Fed. Cir. 1993)). "If the claims read in light of the specification reasonably apprise those skilled in the art of the scope of the invention § 112 demands no more." Id.

There is some ambiguity in the case law as to whether a finding of indefiniteness should occur during claim construction, or whether it should occur at a later step. In Intervet America, Inc. v. Kee-Vet Laboratories, 887 F.2d 1050, 1053 (Fed. Cir. 1989), the Federal Circuit, in discussing claim construction, stated that "ambiguity, undue breadth, vagueness, and triviality are matters which go to claim validity for failure to comply with 35 U.S.C. § 112-P 2, not to interpretation or construction." The Markman decision itself quoted this precise language, albeit in a passage explaining why extrinsic evidence should not be routinely considered in construing claims. Markman, 52 F.3d at 986.

More recent cases, however, have held that a determination of indefiniteness is intertwined with claim construction. "The question of whether claims meet the statutory requirements of § 112 P 2 is a matter of construction of the claims, and receives plenary review on appeal." S3 Inc. v. Nvidia Corp., 259 F.3d 1364, 1367 (Fed. Cir. 2001). See also Atmel Corp. v. Information Storage Devices, Inc., 198 F.3d 1374 (Fed. Cir. 1999) ("An analysis under § 112, P 2 is inextricably intertwined with claim construction[.]"); Personalized Media Communications, 161 F.3d at 705 ("A determination of claim indefiniteness is a legal conclusion that is drawn from the court's performance of its duty as the construer of patent claims."). In two of these cases, however, indefiniteness was considered in the context of a motion for summary judgment; in the third, it was considered after a full factual investigation by the United States International Trade Commission. The Court concludes that the Federal Circuit's statements that indefiniteness is intertwined with claim construction mean only that the Court must attempt to determine what a claim means before it can determine whether the claim is invalid for indefiniteness, and not that the Court must determine indefiniteness during the claim construction proceedings.

In addition, a party seeking to invalidate a claim for indefiniteness has the burden of proving invalidity by clear and convincing evidence. North American Vaccine, inc. v. American Cyanamid Co., 7 F.3d 1571, 1579 (Fed. Cir. 1993).
has not even filed a motion seeking to invalidate any of the claims of the '590 patent on the basis of indefiniteness, but simply asserts its arguments in its opposition claim construction brief. This is not a preferable procedure.

Genus' arguments about indefiniteness are also somewhat entangled in issues relating to lack of enablement under § 112 P 1. Genus' first argument is that it is technologically impossible for one of ordinary skill in the art to determine if more than 99% of the reactant residues are removed from the reaction space. In essence, Genus is arguing that the '590 patent does not, and cannot, teach how to measure whether the reactant residues are removed to a level of less than 1%. "Although not explicitly stated in section 112, to be enabling, the specification of a patent must teach those skilled in the art how to make and use the full scope of the claimed invention without 'undue experimentation'." In re Wright, 999 F.2d 1557, 1561 (Fed. Cir. 1993) (citations omitted). "Even if the written description does not enable the claims, the claim language itself may still be definite." Union Pacific Resources Co. v. Chesapeake Energy Corp., 236 F.3d 684, 692 (Fed. Cir. 2001). Thus, if a person of ordinary skill in the art can determine what the claim language means, but the specification does not show how to perform the invention, the claim may be invalid for lack of enablement, not for indefiniteness. Because analysis of enablement focuses on the adequacy of the specification in teaching a person of ordinary skill in the art how to make and use the invention, it cannot be considered to be part of claim construction.

For these reasons, the Court will not consider Genus' arguments about invalidity of the claims for indefiniteness in this claim construction proceeding. Genus may raise these arguments in a summary judgment motion at a later date.

Turning back to claim construction, the Court first notes one area of agreement between the parties. Although the parties once disagreed on the meaning of "adsorbed," they now agree that "adsorbed" means "adhered to the surface." At the claim construction hearing, some potential disputes arose as to whether this included both chemisorbed and physisorbed material. As this issue was not briefed, the Court declines to resolve it at this time. The Court notes, however, that the patent does not make any explicit distinction between chemisorbed and physisorbed material.

The parties' area of disagreement is over the meaning of the phrase "removed to a level of less than 1%." Genus argues that this language can be measured in two different ways, depending on whether or not the gas reactants are considered together with the adsorbed reactants, and that there is nothing to indicate which way is actually meant. The two methods Genus identifies are:

1. The total amount of reactants present either adsorbed on the inner walls or in the gas phase in the reaction space when the evacuation step ends is less than 1% of the total amount present when the evacuation began; or

2. The amount of reactants adsorbed on inner walls when the evacuation step ends is less than 1% of the amount of reactants adsorbed on inner walls when the evacuation step begins, and the amount of reactants in the gas phase in the reaction space when the evacuation step ends is less than 1% of the amount of reactants in the gas phase in the reaction space when the evacuation step begins.

ASM argues that the person of ordinary skill in the art would recognize that the first method of calculation is the appropriate one. ASM is correct. The specification notes that one of the problems the patent seeks to address is preventing the premature mutual reactions of the reactant gases, which can cause unwanted chemical vapor deposition ("CVD") film formation and dust. ( '590 patent 7:57-64.) Simply keeping the gases separate is not enough "because mixing may also occur due to adherence of molecules from a starting material pulse on the apparatus walls or discontinuities thereof, wherefrom the molecules may then gain access with the molecules of the successive starting material pulse." (Id. 3:13-19.) Therefore, before introducing the next reactant gas, it is important to try to remove not only the reactant gas vapors, but also the molecules that are adsorbed on the walls. Both the gaseous molecules and the adsorbed molecules can react with the next reactant gas. Thus, there is no reason to differentiate between and separately measure the amount of gaseous molecules removed from the reaction space from the amount of adsorbed molecules removed from the reaction space; the point is to try to remove substantially all of them.

The Court generally agrees with ASM about the appropriate construction of this claim language, although it finds that ASM's proposed construction is unnecessarily verbose. Instead, the Court adopts the following construction: "More than 99% of the combined total amount of the unreacted reactants remaining in the reaction space and those adsorbed on the inner walls of the reaction space are removed before the inflow of a second pulse."
Claim 5

Claim 5 depends from claim 1 and includes all of the limitations of claim 1. Similar to Phrase 6 from claim 1 discussed above, this claim further recites that the invention comprises "a substantially axial annular groove" which separates "the annular peripheral zone from the central zone." The parties' dispute centers once more on the word "annular." Plaintiffs argue that annular has its ordinary meaning, referring to "a thing in the form of a ring." Defendants assert, more particularly, that claim 5 requires a circular groove.

There is nothing in the claim or the disclosure of the patent that indicates that the annular groove must be circular. As discussed with regard to phrase 6 from claim 1, although the exemplary embodiment is round or circular, see Fig. 2; 1:8-10; 3:1-5; Fig. 8; 5:6, it is inappropriate to limit the claim by imposing a limitation found, not in the claim, but only in the specification or drawing, or only in a preferred embodiment. See Phillips v. AWH Corp., 415 F.3d 1303, 1320 (Fed. Cir. 2005). Accordingly, the Court finds no basis for limiting the claim.

B. Effect of Prior Litigation

As stated above, SunTiger prevailed in a prior patent infringement suit against Scientific Research Funding Group (SRFG) on the same patents now in question. Both SunTiger and Sunglass Products have stipulated that the claim construction in the prior suit will control here:

The patents-in-suit have already been construed by the U.S. District Court for the Eastern District of Virginia [and that] construction is binding on the parties in this case. To the extent that the terms in the asserted claims were not construed in the said prior litigation, the parties are asking the Court to make a claim construction based on the arguments submitted in the summary judgment motions.

Stipulation at 1-2. "In a patent litigation action, where the parties do not dispute any relevant facts regarding the accused product but disagree over possible claim interpretations, the question of literal infringement collapses into claim construction and is amenable to summary judgment." Rheox, Inc. v. Entact, Inc., 276 F.3d 1319, 1324 (Fed. Cir. 2002).

The relevant terms and their stipulated construction are as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Stipulated Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;substantially block&quot;</td>
<td>&quot;... in reference to wavelengths, it is defined as blocking over 99% of the incident radiation at each and every wavelength&quot; and &quot;[in] reference to polarization, it is defined as blocking 80% or more of the horizontally polarized incident radiation at each and every wavelength&quot;</td>
</tr>
<tr>
<td>&quot;substantially transmit&quot;</td>
<td>&quot;... in reference to wavelengths, [it] is defined as transmitting more than 1% of the incident radiation at each and every wavelength&quot; and &quot;[in] reference to polarization, it is defined as transmitting more than 20% of the horizontally polarized incident radiation at each and every wavelength&quot;</td>
</tr>
<tr>
<td>&quot;sharp cut-on&quot;</td>
<td>&quot;... sharp cut-on is defined in the context of a dye or filter, having a cut-on slope that at some concentration or dye density rises more than one half percent (0.5%) change in transmission for every one nanometer of...&quot;</td>
</tr>
</tbody>
</table>
increasing wavelength change. The cut-on slope is that portion of the transmission spectra of a cut-on dye that represents the transition between [the] substantially blocking and the substantially transmitting region."

"cut-on filter" . . . an optical filter that substantially blocks all wavelengths shorter than the cut-on wavelength and substantially transmits all wavelengths that are longer than the cut-on wavelength. The cut-on wavelength is that wavelength in the transition zone at which the transmission is 1%."

"portion" . . . part or share of something

Plaintiff SunTiger contends that this Court cannot apply the stipulated construction in a way that would contradict the finding of the Eastern District of Virginia that YE-82 infringed SunTiger's patents. Pl.'s Mot. at 1 ("[T]he YE-82 lens material must literally infringe whatever claim construction the Court adopts in this case."). In essence, SunTiger argues the following: (1) the parties have stipulated to the prior construction, (2) the decision in the prior suit does not bind this Court, but (3) any ruling that this Court issues must not be inconsistent with the fact that YE-82 was found to infringe its patents.

I disagree with this assessment. My decision is not foreordained by the result in SunTiger, Inc. v. Scientific Research Funding Group. SunTiger attempts to elevate the prior claim construction to the level of a decision. Despite the parties' agreement that the prior claim construction would be binding, that prior court's decision applying its own construction is only persuasive. Although the parties have agreed to be bound to the use of the prior claim construction, they have not agreed that this Court's application of that construction must be consistent with prior decisions involving a different defendant and different lenses. Indeed, were consistency with prior results necessary, that would be tantamount to an improper form of collateral estoppel against a current party, i.e., Sunglass Products, which was not a party (nor a party in privity) to SunTiger v. Scientific Research Funding Group. Cf. MCA Records, Inc. v. Charly Records, Ltd., 865 F.Supp. 649, 654 (C.D. Cal. 1994) ("[D]ue process requires that the party to be estopped must have had an identity or community of interest with, and adequate representation by, the losing party in the first action as well as that the circumstances must have been such that the party to be estopped should reasonably have expected to be bound by the prior adjudication.").

We next turn to Polypap's contention that the district court erred in concluding that the limitation calling for overlapping folds of the assembly of the asserted patents to be "substantially bonded" to mean that the bonding called for in the claims could be done with "a band or bonding material." Polypap argues that the relevant definition of "substantially bonded" means "composed of two or more layers or the same or different fabrics held together by an adhesive." Webster's Ninth New Collegiate Dictionary 166 (1986). Thus, Polypap concludes that there is an independent basis that the claims at issue are not literally infringed, "because no adhesives or heat seals are used or suggested for use as part of the making of the Bouquett'O."

We conclude that the district court did not err in construing the "substantially bonded" limitation. A reading of the claims leads to the conclusion that the overlapping folds be "substantially bonded via the means for forming the crimped portion." '856 patent, col. 8, ll. 38-39 (emphasis added). An example of "forming the crimped portion" is the placement of a band. Id. at col. 4, ll. 33-35 ("As shown in FIG. 2, the crimped portion 32 is formed by placing a band 34 about a portion of the sheet of material 10 . . . ."). The written description defines "band" as follows:

The term "band" as used herein, means any material which may be secured about an object such as the flower pot 16 such
bands commonly being referred to as elastic bands or rubber bands and also includes any other type of material such as a string or elastic piece of material, a ribbon, a piece of paper strip, a piece of plastic strip, a piece of wire, a tie, wrap or twist tie or combination thereof or any other device capable of gathering the sheet of material 10 to removably or substantially permanently form the crimped portion 32 and secure the crimped portion 32 formed in the sheet of material 10.

Id. at col. 4, ll. 40-53. Thus, "substantially bonded" does not require that the overlapping fold in the sheet of material be substantially bonded by an adhesive. Rather, the "substantially bonded" limitation requires that the overlapping fold in the sheet of material be gathered or crimped about the upper end of the floral holding material by a band or bonding material.

Polytap also argues that, under our construction of the "substantially bonded" limitation, claims 1, 15, 29, and 39 of the '856 patent are invalid as anticipated or obvious. This argument is premature and is not before us on appeal. Contrary to Polytap's contention, we need not invalidate the '856 patent because the invalidity argument was raised only as an affirmative defense by Polytap, not in the form of a counterclaim, and the district court denied as moot Prima Tek's motion for summary judgment regarding Polytap's affirmative defenses. See, e.g., Cardinal Chem. Co. v. Morton Int'l, Inc., 508 U.S. 83, 93-94, 124 L. Ed. 2d 1, 113 S. Ct. 1967 (1993) (distinguishing between asserting an affirmative defense of invalidity and filing a patent counterclaim for declaratory judgment of invalidity). The district court judgment contained no reference to the issue of invalidity of the '856 or '532 patent, and the district court's resolution of the issue of invalidity as an affirmative defense was not necessary to judgment. For that reason, nothing in this opinion or the district court's judgment regarding Polytap's affirmative defense of invalidity should have any preclusive effect on Polytap's ability to argue invalidity on remand. Parklane Hosiery Corp. v. Shore, 439 U.S. 322, 326 n.5, 58 L. Ed. 2d 552, 99 S. Ct. 645 (1979) (stating for collateral estoppel to apply, first court's resolution of the issue in question must have been "necessary to the outcome of the first action"); Restatement (Second) of Judgments § 27 cmt. h, illus. 14 (1982) (explaining that in suit for trademark infringement, a finding that the trademark is valid but not infringed does not preclude the same defendant from asserting the defense of invalidity in subsequent litigation between the parties).

In sum, we conclude that, when viewed as a whole, the claim language, the written description, and the prosecution history require that the "floral holding material" have an upper end, a lower end, an outer peripheral surface, and be constructed of a substance capable of receiving and supporting a floral grouping without any pot means. Moreover, the "substantially bonded" limitation requires that the overlapping folds in the sheet of material be gathered or crimped about the upper end of the floral holding material by a band or bonding material.

The parties dispute the meaning of the phrase "substantially close off contact between combustible material involved in fire and ambient atmosphere," each party offering two different constructions for this term. Defendants argue that "substantially close off contact" means the same thing as seal. Claim 4 of the '965 patent teaches that the expanded foam fire suppressant is what "substantially closes off contact" between the atmosphere and the burning material. '965 patent, claim 4. There is no support for Defendants' proposal that the foam creates a seal. The foam creates a barrier to prevent air, or other gaseous fuel, from feeding the fire. The Court construes "substantially close off contact between combustible material involved in fire and ambient atmosphere" to mean "create a barrier between combustible material involved in fire and ambient atmosphere."
D. The Diameter of the Liner

Claim 12(a) provides "an elongate hollow liner . . . having an original outer diameter substantially comparable to the inside diameter of the pipe to be lined . . . ." (D.I. 17, Ex. 3, col. 10, lns. 63-68) The parties dispute the scope of the term "substantially comparable to." Defendant contends in its claim construction briefs that "substantially comparable to" means the liner must be equal to or larger in diameter than the host pipe. (D.I. 121 at 22) Plaintiffs argue that "substantially comparable to" encompasses pipe liners "slightly less than, equal to, or slightly greater than the host pipes into which they are being installed." (D.I. 127 at 15)

The ordinary meaning of "substantially comparable to" the inside diameter of the pipe includes diameters slightly less than, equal to, or slightly greater than the host pipe diameter. "Substantial" is defined as "being that specified to a large degree or in the main." Webster's at 2280. A liner diameter that is "to a large degree" comparable to the diameter of a host pipe includes liner diameters that approximate the diameter of the host pipe. Thus, pipe liners with diameters that "substantially compare to" the diameters of their host pipes include diameters slightly smaller than, equal to, or slightly greater than the host pipe diameter.

Defendant, however, contends that the ordinary meaning of "substantially comparable to" does not control because the intrinsic evidence of the '196 patent is inconsistent with this meaning. Only two situations provide sufficient justification for defining a claim term in a manner other than its ordinary and accustomed meaning. See Johnson Worldwide Assocs., Inc. v. Zecco Corp., 175 F.3d 985, 990 (Fed. Cir. 1999). The first of those situations occurs when a patentee has chosen to be his or her own lexicographer by clearly setting forth an explicit definition for a claim term. See id. This is not the case here. The other situation occurs when the term or terms chosen by the patentee so deprive the claim of clarity that there is no means by which the scope of the claim may be ascertained from the language used. See id.

Defendant urges that the intrinsic evidence of the '196 patent deprives the term "substantially comparable to" of its ordinary meaning. Defendant specifically points to the '365 patent specification, which explains that,

> in practice, the liner configuration has an outside diameter equal to or slightly greater than the inside diameter of the pipe to be protected, whereby the said liner is either unstressed or under slight circumferential compression . . . .

(D.I. 65, Tab 1, Ex. C., col. 1, lns. 40-47) (emphasis added). Defendant also notes that the '196 patent specification describes the preferred embodiment as having "a diameter slightly larger than the interior diameter of the pipe to be lined." (D.I. 17, Ex. 3, col. 1, lns. 65-69) (emphasis added). Each of these specifications, however, describes the preferred embodiment, and a description of the preferred embodiment cannot limit a claim term. See, e.g., Johnson Worldwide Assocs., 175 F.3d at 992. Moreover, defendant admitted in its reply brief in support of summary judgment that claim 12 "is broad and necessarily covers diameters that are smaller than the pipe to be lined." (D.I. 71 at 19) Accordingly, there is no compelling reason to deprive the term "substantially comparable to" of its ordinary meaning. The court shall construe the term "substantially comparable to" as encompassing pipe liners slightly less than, equal to, or slightly greater than the host pipes into which they are being installed.

With these constructions of the disputed claims in mind, the court now turns to defendant's motion for summary judgment.
test. LNP's proposed construction, which was largely adopted by the court, stated that "substantially completely wetted" meant that the filaments be "largely, but not necessarily wholly, surrounded by resin." As a measure to quantify the degree of wetting, LNP's proposed construction, as is recited in the claim language, recites use of the dispersal/length test.

RTP, on the other hand, sought to construe the term "substantially completely wetted" in reference to the flexural modulus test. RTP noted that the specification and the prosecution history of the patents in suit used the flexural modulus test to characterize the claimed plastics, and to distinguish them from products in the prior art. As such, RTP advocated incorporating language from the specification into the construction of the claims, and asserted that "substantially completely wetted" means the product must attain at least 90% of the theoretically attainable flexural modulus.

The court rejected RTP's proposed construction. The court reasoned that the flexural modulus test was only an indirect test that did not directly measure the characteristics of the claimed wetted strand and pellets. Moreover, the court found that the prosecution history of the patents did not compel a finding that the term "substantially completely wetted" is tied to the flexural modulus test. Thus, the court concluded that the term "substantially completely wetted" should be defined in terms of the dispersal/length test, as follows:

Largely, but not necessarily wholly, surrounded by resin. In the context of LFRT pellets, it is surrounding the individual filaments by resin to the extent that in articles injection molded from such pellets, the individual filaments are randomly dispersed and at least 50% by weight of the filaments retain a length of 2 millimeters or greater.

A. Reconsideration of Claim Construction

RTP has moved for the court to reconsider its construction of the claim term "substantially completely wetted." RTP seeks reconsideration in two contexts. First, it asserts that the court should define the claim term in relation to the flexural modulus test for determining wettedness. RTP notes that the court's present construction, which defines wettedness in relation to the dispersal/length test, creates "an ever-changing definition of infringement." RTP argues that improvements in injection molding technology will permit LFRT pellets of poorer quality to yield molded products with sufficiently long and dispersed filaments. It is improper, RTP argues, to establish infringement criteria in relation to technology outside the scope of the patent claims.

RTP's second argument is that the court should reconstrue the claims of the '450 patent, as reexamined, and the '889 patent, as reexamined, and find that the claim term "substantially completely wetted" is a distinct claim limitation.

As a procedural matter, the court may reconsider a prior ruling in three circumstances: 1) where the court has patently misunderstood a party; 2) where the court has made a decision outside the adversarial issues presented to the court by the parties; or 3) where the court has made an error not of reasoning but of apprehension. Stairmaster Sports/Medical Products, Inc. v. Groupe Procycle, Inc., 25 F. Supp. 2d 270, 292 (D. Del. 1998). The issues presented to the court for reconsideration were directly addressed by the court in its Markman opinion. Because the court therein apprehended the arguments, and resolved them, there are no procedural grounds for reconsidering these issues in the present posture. For the benefit of the record, the court will consider the motion on its merits.

The challenged claims relate to LFRTs wherein the reinforcement filaments are "substantially completely wetted." To measure the degree of wettedness, the claims, as construed by the court, call for a determination of whether the filaments in the molded sample are randomly dispersed and sufficiently long. While this method may present complications by tying the threshold of infringement to the state of the art in injection molding technology, the same difficulties would be present if "substantially completely wetted" were measured in terms of the flexural modulus test. It was undisputed at trial that the flexural modulus test cannot be performed on a pellet. RTP's proposed construction thus requires that the strand or pellets be injection molded prior to analysis by the flexural modulus test. This measure of infringement would suffer from the same alleged deficiencies as the dispersal/length test.

Second, RTP asserts that the term "substantially completely wetted," as it appears in claim 1 of the '450 patent, as
reexamined, and claim 1 of the '889 patent, as reexamined, should be a distinct claim limitation. RTP notes that both these patents, prior to being reexamined, recited the dispersal/length test as a means to determine the strength of the plastic, but that neither of the patents contained the claim term "substantially completely wetted." This term, RTP recognizes, was introduced into the claims during reexamination, with neither the '450 patent nor the '889 patent originally reciting this language. RTP reasons that the introduction of the term "substantially completely wetted" constitutes a further limitation upon the claims, and that this limitation serves to restrict the range of plastics covered by the claims. See Laitram Corporation v. NEC Corporation, 163 F.3d 1342, 1347 (Fed. Cir. 1998).

--- Footnotes ---

3 Claim 1 of the '450 patent, as originally issued, reads:

1. Pellets of reinforced thermoplastics material containing at least 30% by volume of parallel, aligned reinforcing filaments between 2 and 100 mm in length, the filaments extending through the length of the pellets, the pellets having been cut from a continuous reinforced product prepared by melt protrusion and which pellets can be injection moulded into an article in which the fibres are present in the form of randomly dispersed individual filaments at least 50% by weight of the filaments of the pellets retaining a length of greater than 2 mm in the moulded article.

4 Claim 1 of the '889 patent, as originally issued, reads:

A molded article formed from a fibre reinforced thermoplastic composition in a process which includes the step of melting and homogenizing a composition containing at least 30% by weight of fiber reinforced pellets between 2 mm and 100 mm long which pelts have filaments extending the length of the pellet, characterized in that the molded article contains reinforcing filaments in the form of individual filaments and at least 50% by weight of the filaments in the pellets being present in the molded article at a length of greater than 2 mm, the pellets having been cut from a structure of continuous, parallel, aligned, reinforcing filaments which have been wetted by a molten

--- End Footnotes ---

The history of the reexamination of the patents indicates that the court's construction of the claims in question need not be amended. The file history of the '450 patent shows that the term "substantially completely wetted" was introduced into claim 1 not to distinguish the claim from the prior art, but to provide an antecedent basis for terms recited in claim 6 of the patent.

For the '889 patent, the file history indicates that the term "substantially completely wetted" was introduced to distinguish the claims from the prior art. The examiner found that the British GB-849 reference, and the JP-653 reference, anticipated claim 1, as originally issued. The applicant indicated that these references disclosed that the plastic products claimed therein suffered from a lack of adequate wetting of the reinforcement filaments. The applicant thus introduced the language "substantially completely" to modify the term "wetting" as originally recited. The added language serves to limit the scope of the claims to those plastics where the filaments are substantially completely wetted, and where the filaments are not bundled and loose, as characterized the referenced prior art products. The court's claim construction, which states that the filaments must be "largely, but not necessarily wholly, surrounded by resin," adequately reflects this structural limitation, and does not require reconstruction.

For these reasons, RTP's motion for reconsideration of the court's claim construction is denied.

GO BACK

3869

The district court in the present case construed the term "substantially completely wetted" of claim 1 of both the 450 and 889 patents to mean:

Largely, but not necessarily wholly, surrounded by resin. In the context of LFRT pellets, it is surrounding the individual filaments by resin to the extent that in articles injection molded from such pellets, the individual filaments are randomly dispersed and at least 50% by weight of the filaments retain a length of 2 millimeters or greater.
LNP, No. 96-462-RRM, slip op. at 17 (D. Del. Dec. 17, 1999). Thus, the court defined this claim term according to the dispersal and length test, and not by the flexural modulus test.

The meaning of the word "substantially" is "largely but not wholly that which is specified." Webster's Ninth New Collegiate Dictionary 1176 (9th ed. 1983). According to both parties' explanations of the technology, "completely wetted" means "wholly surrounded by resin." Therefore, the claim language supports the correctness of the district court's interpretation of "substantially completely wetted" as "largely, but not necessarily wholly, surrounded by resin." See Ecolab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1369, 60 U.S.P.Q.2D (BNA) 1173, -- (Fed. Cir. 2001) ("substantially uniform" means "largely, but not wholly" the same in form).

Neither claim at issue mentions the flexural modulus test nor refers even obliquely to that test as a limitation. Claim 6 of the 450 patent, which depends from claim 1, however, recites:

6. Pellets according to claim 1 which have been cut from a continuous reinforced product in which the individual filaments of the product have been wetted to the extent that the longitudinal flexural modulus of the product as determined by ASTM D790-80 is at least 70% of the theoretically attainable flexural modulus.

United States Patent No. B1 5,019,450, col. 2, ll. 9-14 (indications of change removed and emphasis added). Thus, dependent claim 6, presumptively narrower than claim 1, adds a specific flexural modulus limitation of at least 70%. This narrower claim at least opens the possibility that the broader "substantially completely wetted" language of claim 1 of the 450 patent embraces more than a flexural modulus of at least 70%.

Moreover, claim 3 of the 262 patent recites:

A thermoformable fibre reinforced structure comprising a thermoplastic polymer and at least 30% by volume of parallel, aligned reinforcing filaments . . . said filaments being substantially completely wetted by thermoplastic polymer characterized in that when the structure is chopped into moulding pellets between 2 mm and 100 mm in length and formed into a shaped article by a process which includes the step of subjecting the pellets to a melt homogenisation process to produce a random distribution of individual filaments in molten polymer, the fibre length is retained to the extent that at least 50% by weight of the filaments are at least 2 mm long.

col. 28, ll. 31-43 (emphasis added). Thus, the parent patent to both the 450 and 889 patents defines "substantially completely wetted" according to length and dispersal and does not incorporate any flexural modulus requirement. Again this evidence suggests that "substantially completely wetted" is not limited to a specific flexural modulus result.

As mentioned above, the term "substantially completely wetted" is neither recited nor specifically defined anywhere in the written description of the patents. The written description does explain the flexural modulus test and recites it throughout as a measure of LFRT strength. The trial record as well as the written description shows that flexural modulus is a typical way to measure LFRT strength and, therefore, degree of wettedness. The written description also explains good wetting results in terms of fiber length and fiber dispersal. See, e.g., 450 Patent, col. 9, ll. 24-26, ll. 29-37, col. 10, ll. 6-17, col. 16, ll. 19-24, col. 21, ll. 28-31. Again, the written description does not limit claim 1 by any flexural modulus test result.

The prosecution history also does not indicate that the claim terms require flexural modulus testing. 1 The patent owner added the terms "substantially completely" to claim 1 of the 889 patent during the reexamination proceeding. As originally filed, claim 1 only recited "wetted." In the 450 patent, the patent owner added the entire term "substantially completely wetted" to claim 1 during reexamination. Because the claims recited filament length and dispersal before reexamination, RTP argues that the district court's construction writes the term "substantially completely wetted" out of the claim by defining it in terms of length and dispersal.

1 RTP argues also that during prosecution of the 262 patent, LNP defined "substantially completely wetted" to require a flexural modulus of at least 90%. However, it is clear, when the prosecution history is viewed in context, that LNP referred to the 90% flexural modulus with respect to a preferred embodiment of its invention rather than as a limitation upon the scope of the invention. Gart v. Logitech, Inc., 254 F.3d 1334, 1343, 59 U.S.P.Q.2D (BNA) 1290, -- (Fed. Cir. 2001) (noting
that "it is well established that broad claims supported by the written description should not be limited in their interpretation to a preferred embodiment"). Dependent claim 6 of the 450 patent reinforces this understanding by including an explicit limitation that the flexural modulus be at least 70%.

During the reexamination proceedings, LNP amended claim 1 of the 889 patent to add "substantially completely" as a modifier for "wetted" explaining:

Claim 1 has . . . been amended to clarify the melt pulltrusion process which results in the individual filaments in the molded article and to avoid a possible trivial and unintended interpretation of the claim which might be read to cover molded articles with substantial unwetted filament bundles and a small amount of individual filaments.

(emphasis added). LNP amended claim 1 of the 450 patent to add "substantially completely wetted" explaining: "Claim 1 has been amended . . . to clarify the melt protrusion process which results in individual filaments in the molded article, and to provide antecedent basis for 'wetted' in claim 6." (emphasis added). As support for these amendments, LNP cited to sections of the written description that disclose wetting the surface of individual filaments to obtain high levels of flexural modulus (450 Patent, col. 3, ll. 42-58), retention of fiber length by virtue of good wetting (450 Patent, col. 9, ll. 32-38), and a percent weight comparison between completely wetted product with product of an unknown extent of wetting (450 Patent, col. 11, Example 1).

During reexamination, the PTO examiner made prior art rejections for both patents based on the GB-849 reference, the British counterpart of United States Patent No. 4,037,011 to Hattori. As part of its response, LNP explained:

When there is substantial complete wetting of the filaments in the pellets, the pellets can be injection molded into an article in which the filaments are present in the form of individual filaments having excellent filament length retention and which has an excellent cosmetic appearance without visible bundling of filaments.

LNP further explained: "GB-849 does not anticipate the claimed invention as it does not inherently teach or suggest a molded articles [sic] in which the filaments are found as individual filaments due to a high degree of wetting." The reexamination history of both patents thus supports that "substantially completely" and "substantially completely wetted" were added to the claims as clarifications, not as additional limitations.

In sum, this court has reviewed the claim language, specification language, and prosecution history, and finds that the record supports the district court's interpretation. The district court thus correctly concluded that "substantially completely wetted" means "largely, but not necessarily wholly, surrounded by resin." Moreover the district court correctly determined that a flexural modulus test result does not limit claim 1 of both patents.

76. Elements [a], [b], and [c] of Claim 9 are virtually identical to the same elements of Claim 1, so the discussion with respect to them is the same.

77. Element [d] of Claim 9 is identical to element [e] of Claim 1. There is no limitation at all with respect to the locking means in this claim. Instead, this claim includes element [e], which describes the first portion as comprising "a substantially conical base portion" and a second portion which "comprises a substantially conical portion."

78. The word "comprise" means "include." RANDOM HOUSE DICTIONARY OF THE ENGLISH Language, page 303. Thus, the phrase, "comprises a substantially conical base portion," means that the first portion includes a base portion mostly but not necessarily perfectly conical in any cross section. Similarly, "comprises a substantially conical upper portion" means that the second portion includes an upper portion that is mostly but not necessarily perfectly conical in any cross section.

79. The word "conical" is defined in THE RANDOM HOUSE DICTIONARY OF THE ENGLISH LANGUAGE as
Con-ic (kon' ik), adj. 1. Also con'-i-cal. Having the form of, resembling, or pertaining to a cone. . . .

Thus, the word conical does not require that the form be exactly in the shape of a cone.

D. Dependent Claim 13: "substantially conjugated" 21

A method according to claim 12, wherein: said area is substantially conjugated with one of said first and second of the increased intensity portions.

Id. at 20:4-6.

The parties seem to agree that "substantially conjugated" possesses meaning customary to those of ordinary skilled in the art, viz., the near-complete mapping of the points of one plane in an optical system to a second plane. As the court reads their proposed constructions, moreover, the parties generally agree that, in the context of claim 13, "substantially conjugated" denotes the relation of a given plane to the first or second portion of increased light intensity. All that remains, then, is semantics, with ASML asserting that "substantially conjugated" should be read in one detailed manner, Nikon arguing that the term should be read in another, equally detailed manner.

Despite the parties' attempts to fill "substantially conjugated" with overflowing detail, neither party offers a construction that readily fits the context in which the term is used. In the relevant claim context, "substantially" denotes the degree to which two locations or positions are conjugated; that is, as claim 13 uses the term, to be "substantially conjugated" is to be conjugated to a significant degree. Cf. Cordis Corp. v. Medtronic Ave, Inc., 339 F.3d 1352, 1360 (Fed. Cir. 2003) (discussing the meaning of "substantially"); Epcon Gas Sys., Inc. v. Bauer Compressors, Inc., 279 F.3d 1022, 1031 (Fed. Cir. 2002) (same). In the relevant claim context, in turn, "conjugated" describes any pair of locations positioned such that points of the first map--or are amenable to mapping or imaging--to the neighboring points of the second. The teachings of the specification language are in accord. See '041 Patent at 11:60-12:11. Under the terms of claim 13, it is an "area" that to be "substantially conjugated," so "conjugated" denotes an "area" positioned such that its points map the neighboring points of "one of . . . the increased in intensity portions." Taking the definitions of "substantially" and "conjugated" together, the term "substantially conjugated" means "positioned such that the area's points map or image to a significant degree to the corresponding points of another area or plane." 22 Nikon's proposed appendix concerning "all light rays" is simply extraneous to the relevant term.

22 Fit into the terms of claim 13, then, an "area" is "substantially conjugated" when it is positioned such that the area's points map substantially the corresponding points of another area or plane.

2. The Definition of "Substantially Constant Wall Thickness"
As the Federal Circuit's opinion in this case indicated, the phrase "substantially constant wall thickness" must be construed according to "how the phrase would be understood by persons experienced in this field of mechanics, upon reading the patent documents." Verve, 311 F.3d at 1120. In this case, the parties have presented testimony from two expert witnesses as to the meaning of the phrase "substantially constant wall thickness."

Plaintiff's expert witness, Dr. David Bourell, testified by declaration as follows:

Claim 1 also requires that the tube have a "substantially constant wall thickness" throughout its length and the tips thereon. This term also has its ordinary meaning. I understand the term substantially to mean to a large or considerable degree. Thus, wall thickness throughout the length of the tube must be largely or considerably constant. Based on my review of the push rods, and based on my understanding in engineering principles (sic), the starting stock from which push rods are formed has relatively large tolerances or large variations in the wall thickness prior to any processing. Thus, at a minimum, if the wall thickness of the tube after formation is still within the accepted industry tolerances for the tube prior to formation, then the wall thickness can be considered substantially constant.

Bourell Declaration, § 9.

Defendant's expert, Dr. Lee Swanger, testified at the Markman hearing on March 23, 2004 as to his understanding of the term "substantially constant wall thickness," stating that the term is as the Court has held in its claim construction. That it is a measure between the thickest and thinnest part of the wall of the push rod. And up until I saw a piece of paper with a blank in it, that difference had been 20 percent.

Markman Hearing Tran., 3/23/04, 37.

Dr. Swanger also testified as to other bases for his definition of the term "substantially constant wall thickness." First, Dr. Swanger stated he arrived at the 20 percent figure by relying on Plaintiff's statement on appeal in the Federal Circuit. Markman Hearing Tran., 3/23/04, 45. Second, Dr. Swanger testified that a General Motors push rod design from the 1960's, when analyzed according to the Court's current claim construction, would result in "a backing up of the 20 percent as being an extreme example of the kind of variation that one familiar with push rods would call substantially uniform." Markman Hearing Tran., 3/23/04, 45-6.

Dr. Swanger's reference to the General Motors blueprint provides some context for how persons in the field might interpret the claim term. However, the basis for his reading of the GM blueprint is this Court's claim construction and Plaintiff's statement on appeal, which are not probative of the term's meaning to persons of ordinary skill in the art. Therefore, Dr. Swanger's testimony is not helpful to the Court in performing the task at hand, which is to determine "how the phrase would be understood by persons experienced in this field of mechanics, upon reading the patent documents." See Verve, 311 F.3d at 1120.

Dr. Swanger also testified that "for some reasons" he would agree with Dr. Bourell's definition of "substantially constant wall thickness." Markman Hearing Tran., 3/23/04, 47.

Most importantly, Dr. Swanger testified that the "thickest-to-thinnest" methodology is not specified anywhere in the '315 patent, that this methodology is not specified anywhere in the prosecution history of the '315 patent, that the '315 patent does not set forth any percentages for what would constitute "substantially constant wall thickness," and that the prosecution history for the '315 patent does not set forth any percentages for what would constitute "substantially constant wall thickness." Markman Hearing Tran., 3/23/04, 37-8.

While Dr. Swanger's testimony supports Defendants' contention that the '315 patent is indefinite, it also supports Plaintiff's argument that the '315 patent does not require a particular measurement methodology for ascertaining wall thickness variation. Therefore, the Court finds that persons experienced in the field would not decide upon a numerical construction of the phrase "substantially constant wall thickness" upon reading that phrase in the patent documents.

Applying the law of the Federal Circuit as stated in Cordis, supra and Playtex, supra, the Court concludes that its current
claim construction is improper because it impermissibly introduces a numerical value to the definition of "substantially constant wall thickness." The Court is persuaded by Dr. Swanger's testimony at the Markman hearing that neither the terms of the patent, nor its prosecution history, specify a method or percentage for gauging wall thickness variation. Therefore, the prosecution history of the '315 patent cannot be said to include the type of "clear and unmistakable disclaimer" necessary to abandon the limitation imposed by the plain language of the claim. See Cordis, 339 F.3d at 1361.

Based on the foregoing, the Court hereby amends its claim construction to state that the term "substantially constant wall thickness" shall be construed as "wall thickness that is to a large or considerable degree constant." In future proceedings before the Court, the parties may present evidence as to competing methodologies for measuring wall thickness variation. However, the Court finds that the question of which methodology should be used is a fact question for the jury. The Court will not settle upon one particular method for measuring wall thickness as a matter of claim construction because such a decision is not required by the claim language.

2) "Substantially continuously deformable"

Defendant argues that Plaintiff has impermissibly broadened the Patent in Suit during reexamination by substituting "substantially continuously deformable" in Claims 15 and 16 for "continuously deformable" in Claim 1. Defendant relies upon the Quantum decision--and that case's approval of Ex parte Neuwirth--for the proposition that Plaintiff has thereby necessarily broadened the scope of the claims.

Plaintiff, in response, maintains that the phrase "substantially continuously deformable" is identical in meaning to "continuously deformable." In the "real world" of the manufacture of sunshades, Plaintiff argues, there is no such thing as a perfectly "continuously deformable" material. Thus, goes the argument, all materials are at most substantially continuously deformable, and the revised language of the claims only makes clear what was always "implicit and inherent in the operation of the sunshade."

Defendant is clearly correct that the addition of the seemingly innocuous adverb "substantially" can serve to broaden the scope of the claim. In Ex parte Neuwirth, 229 U.S.P.Q. 71 (1985), the PTO Board of Patent Appeals invalidated a claim added during reexamination on this very ground. The Federal Circuit expressly approved this holding in Quantum, 65 F.3d at 1581, and In re Freeman, 30 F.3d at 1464. The Federal Circuit has not, however, laid down a per se rule that "substantially" always broadens the scope of a claim. Ex parte Neuwirth, upon which Defendant relies, is readily distinguishable. That case concerned two claims that were absolutely identical, except for the addition during reexamination of new claim differing by only a single word--"substantially." "'Substantially rounded,'" the PTO Board held, "must mean something different than 'rounded' to preclude an identity between" the two claims. The addition of the "substantially rounded" claim, therefore, necessarily broadened the scope of the original claim. The Board upheld the Examiner's decision rejecting the second, new claim. Ex parte Neuwirth, 229 U.S.P.Q. at 72-73.

Here, by contrast, the Examiner canceled the original Claim 1 and replaced it with Claims 15 and 16, which are identical with respect to the "substantially continuously deformable" language. The court finds this difference decisive. Although in some contexts the addition of a qualifier like "substantially" can be important, the court finds that within the context of the real world art of sunshade design and manufacture, there is no "perfectly continuously deformable" material. Accordingly, Claim 1, sensibly read, never required such an interpretation. A deformable material, within the context of auto sunshades, could be at most "substantially" deformable. The addition of the adverb "substantially," therefore, does not serve to broaden the claim but merely clarifies the language of the earlier claim in accordance with what one skilled in the art of sunshades would always have understood by the term.

3) "Substantially continuously deformable to a predetermined contour of said vehicle window"
This phrase means that the perimeter of the sunshade is capable of bending ("deformable") so as to fit a predetermined contour of a vehicle window. The sunshade is deformable throughout the perimeter. However, it is not "perfectly deformable" but only "substantially" deformable. The phrase does not mean that in operation the sunshade necessarily conforms to the entire periphery of the vehicle window.

Representative claim 1 of the '525 patent reads in pertinent part as follows:

An intraocular lens comprising:

a lens body;

at least two spaced flexible positioning and supporting elements integrally formed with said lens body as a one-piece construction and extending radially, outwardly from the periphery of said lens body;

said elements terminating in a free end spaced from said periphery; and snag-resistant means integrally formed on the free end of each of said elements for smoothly guiding and positioning the lens across contacted eye tissue when implanting the lens . . . said snag resistant elements and said positioning and supporting elements being substantially coplanar.

On January 29, 1993, Pannu sued Iolab, alleging that four types of intraocular lenses manufactured by Iolab infringed the '525 patent. Iolab answered by asserting that the patent was invalid for lack of an enabling description, failure to disclose the best mode, and improper inventorship. Regarding improper inventorship, Iolab argued that the patent was invalid because the '525 patent does not list Link as an inventor. Iolab in fact argued that Link was not only a co-inventor, but the sole inventor, because Pannu, by sending non-confidential letters to lens manufacturers in early 1980, had already placed his contribution to the invention, the snag-resistant loop, in the prior art.

Following a "Markman" hearing, the court construed the terms "snag-resistant means" and "substantially coplanar." Regarding the former limitation, the court determined that the claim recited sufficient structure such that 35 U.S.C. § 112, P 6 (1994) did not apply. The court rejected Iolab's contention that the snag-resistant limitation must prevent any damage to the eye, finding no support for such a construction in the specification or the prosecution history. Instead, the court ruled that the snag-resistant means must be curved so as to minimize snagging, but not necessarily to eliminate it.

Regarding the "substantially coplanar" limitation, Iolab argued that the two supporting elements and the two snag-resistant elements all had to be within the same plane, relying on its expert's testimony that the limitation "describes a flat lens where the elements may deviate from the plane only as the result of manufacturing tolerances or natural flexibility." In contrast, Pannu argued that the term "substantially coplanar" permitted some small angle to exist between the supporting elements and the snag resistant elements. The court, after considering the prosecution history, including drawings submitted by Pannu showing lenses with angles up to ten degrees, agreed with Pannu and construed the limitation as requiring an angle of no more than ten degrees between the snag-resistant elements and the supporting elements. 1

--- Footnotes ---

1 The court further construed the limitation as requiring no more than a ten degree angle between any of the four elements and the lens body. We can find no support for this additional constraint. This error, which was not addressed by the parties, does not affect the outcome of this appeal and is thus harmless.

--- End Footnotes ---

B. Infringement

Iolab also argues that the district court misconstrued two limitations in the claims, and that under the correct claim...
construction, infringement is precluded as a matter of law. First, Iolab argues that the claim limitation "substantially coplanar" must refer to "non-vaulted" lenses, which are flat. Iolab asserts that no other interpretation is supported by the specification or the prosecution history. We disagree.

Claim construction is a question of law, which we review de novo. Cybor Corp., 138 F.3d at 1454, 46 U.S.P.Q.2D (BNA) at 1173. When construing a claim, a court principally consults the intrinsic record, consisting of the claims themselves, the written description portion of the specification, and the prosecution history. See Vitronics Corp. v. Conclip, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2D (BNA) 1573, 1576-77 (Fed. Cir. 1996). The claim term "coplanar" is modified by the term "substantially." The district court properly examined the specification and prosecution history to determine the meaning of the term "substantially coplanar" and construed the term to cover the two examples submitted to the examiner during prosecution of the patent. We discern no error in the court's construction of this term. Iolab's argument that the specification only discloses flat lenses is plainly incorrect. Regarding one embodiment of the invention, the specification states that the rings "lie in a plane sufficiently close to the plane of the lens." This statement clearly contemplates that the rings and the lens lie in different, although close, planes. Additionally, Iolab has not drawn our attention to any portion of the prosecution history that precludes angles as small as ten degrees from being considered substantially coplanar; nor has it suggested a more appropriate angle. Furthermore, there is no support in the patent or prosecution history for Iolab's proposed claim construction. The patent draws no distinction between vaulted and non-vaulted lens; these terms are not even found in the intrinsic documents.

extending substantially coplanar

Plaintiff proposes the following definition: "[S]aid finger plate extending substantially in the same plane as said shield allowing sheets of paper to lie flat atop the ring metal assembly."

Defendants propose the following definition: "The housing having a surface and the finger plate lying entirely within the longitudinal projection of that surface or within standard manufacturing tolerances thereof."

The parties agree that this term is the second of the two most significant terms to be defined in this case. 5

--- Footnotes ---

5 The other is the term "a release lever" in Claim 1, see pages 8-10, supra.

--- End Footnotes ---

Plaintiff refers the Court to the patent specifications which teach that the difference between this invention and other ring binders can be discerned by looking at figures 5 and 6 in the patent.

Because of the construction of a conventional release lever L, the thumb or finger portion of the release lever must extend beyond the end of the sheet of paper by a distance D. [See figure 6.] This is not so with the release mechanism of the lower profile ring metal 20. Now, the end of the ring metal and sheet of paper coincide. . . . Because each release lever 44, 46 [see figure 3] has a, [sic] contour generally corresponding to that of the release lever, the sheets of paper lie flat atop the ring metal assembly.

("729 patent at col. 4, ll. 12-22.) This advantage of the '729 patent is also generally discussed in the background section of the patent. (See id. at col. 1, ll. 26-48.) Plaintiff's definition is consistent with the teachings of the patent specifications. Defendants' proposed definition is not.

Because of the clear language of the teaching of the above-cited specification language, there is no need for extrinsic evidence to define this term. Additionally, there is nothing in the dictionary definition of these two words that is inconsistent with Plaintiff's proposed definition.
For the foregoing reasons, the Court construes the term "extending substantially coplanar" as:

Extending substantially coplanar means said finger plate extends substantially in the same plane as said shield allowing sheets of paper to lie flat atop the ring metal assembly.

4. Substantially cover (claims 22, 37)

Plaintiff contends that "substantially cover" does not need to be construed, while Defendants contend that it should be construed to mean "cover nearly all of." In support, Defendants argue that the resistors illustrated in Figs. 5a and 5b "cover nearly all of" the surface and that a jury would be aided by their proposed construction. Defendants' construction, however, merely replaces the language as drafted with language of no greater clarity. Moreover, "cover nearly all of" is potentially more stringent than "substantially," which would alter the scope of the claim as drafted, and is based solely on a preferred embodiment illustrated in the figures of the '663 patent. See SuperGuide, 358 F.3d at 875.

Because Defendants' proposed construction potentially alters the scope of the term "substantially," and because it does not add clarity to the claim language as drafted, the court declines to construe this term.

2 See U.S. Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir. 1997) ("Claim construction is a matter of resolution of disputed meanings and technical scope, to clarify and when necessary to explain what the patentee covered by the claims . . . .").

D. Substantially Cure

Claims 1 and 10 both describe the level of energy emitted by the cold UV assembly as being effective to "substantially cure the ink." The parties dispute the level of cure that the term "substantially" requires. According to L&P, "substantially cure" must be given its plain and ordinary meaning, "to a great extent or almost completely cured." Vutek, on the other hand, claims that "substantially cure" should be interpreted broadly to mean "at least partially cure so as to freeze dots of ink" as well as greater levels of curing.

The claims themselves offer some insight into the appropriate interpretation of the phrase "substantially cure." First, the use of "substantially cure" in conjunction with the term "freeze" in claims 1 and 10 indicates that "substantially cure" refers to a level of curing above and beyond that which is required to "freeze" dots of ink. Claim 1, which is very similar to claim 10, reads as follows:

A method of ink jet printing …

providing at least one cold UV curing assembly on the carriage, adjacent to and moveable with the printhead, and oriented to direct UV energy onto the surface of the substrate at the printing station sufficiently close to where the ink is being jetted onto the surface to freeze dots of the jetted ink on the surface; and

the cold UV assembly being effective to impinge sufficient UV light on the ink to substantially cure the ink without impinging radiation that would heat the substrate so as to deform it, even temporarily, while at the printing station.
The use of the word "freeze" alongside "substantially cure" implies that the two terms do not mean the same thing. If "substantially cure" simply referred to a level of cure sufficient to "freeze" dots of ink, the phrase would be redundant. Instead, as Codos testified, the words "freeze" and "substantially cure" in claims 1 and 10 describe what is essentially a two-step printing process: first the dot of ink is frozen, then it is substantially cured. According to Whittle, this initial "freezing" step can be accomplished with as little as a one to five-percent cure. Codos explained that depending on the thickness of the ink drop and print speed, among other factors, the two steps can occur instantaneously in a single pass of the printhead. More typically, however, the printhead (and attached UV curing assembly) makes multiple passes over each drop of ink. On each additional pass, the curing, or polymerization, process progresses with the increased exposure to the UV light.

While I recognize that a court should be cautious when considering an inventor's post hoc interpretation of his own patent, the Federal Circuit has held that "[a]n inventor is a competent witness to explain the invention and what was intended to be conveyed by the specification and covered by the claims." Voice Technologies Group, Inc. v. VMC Systems, Inc., 164 F.3d 605, 615 (Fed. Cir. 1999) (citation omitted). This is especially true where, as here, the inventor's interpretation is consistent with the Patent Examiner's interpretation of the Patent. In this case, the Patent Examiner specifically recognized the two-step, freeze-then-substantially-cure, printing process as a basis for allowing the '518 Patent:

The primary reason for the allowance of claims 1-8 and 20 is the inclusion of the limitation of a method of an ink jet printing UV curable ink comprising the combination of two cold UV curing assemblies on the carriage, adjacent to the printhead and movable with the print head, oriented to direct UV energy onto the surface of the substrate at the printing station close to where ink is being jetted onto the surface to freeze dots of the jetted ink on the surface and being effective to impinge sufficient UV light to substantially cure the ink without impinging radiation that would heat the substrate so as to deform it. It is limitation found in each claims, as it is claimed in the combination, that has not been found, taught, or suggested by the prior art of record which makes these claims allowable over the prior art.

(Emphasis added). In sum, I find that a person of ordinary skill in the art would interpret "substantially cure" to refer to a greater level of curing than that which is required to "freeze" dots of ink.

The specification and prosecution history offer little, if any, guidance as to how much more curing "substantially cure" requires above the "freezing" level. The phrase "substantially cure" only appears in claims 1 and 10. There is no mention of the word "substantially" in the specification, nor does the prosecution history use the phrase outside of quotations to the claim language. Thus, I agree with Whittle's observation that a person of ordinary skill in the art would not be able to review the intrinsic evidence of the '518 Patent and identify a specific percentage of monomers that must be polymerized in order to be "substantially cured."

Nevertheless, I do find that the term "substantially" carries an ordinary and customary meaning that would be readily apparent to a person of ordinary skill in the art. "Substantially" is "a term of approximation or a term of magnitude." Deering Precision Instruments, L.L.C. v. Vector Distrib. Sys., 347 F.3d 1314, 1322-23 (Fed. Cir. 2003) (citation omitted). Common definitions of "substantially" include "considerably," "significantly," "largely," or "essentially." Id. at 1323 (citations omitted). L&P's proposed construction, "to a great extent or almost completely cured" captures this ordinary and customary meaning. 4

4 In this case, the term "substantially" could be considered both a term of approximation or a term of magnitude. On one hand, "substantially cure" could refer to the physical state of being fully cured. If this were the case, "substantially" functions as a term of approximation. On the other hand, "substantially cure" could refer to the number of ink monomers that have polymerized. "Substantially" would then serve as a term connoting magnitude. The difference between these two interpretations is immaterial in the present case, in contrast to the facts of Deering.

Vutek contends that the use of "at least partially cure" in claim 5 indicates that "substantially cure" in the '518 Patent covers a broader range of cure levels than the ordinary and customary meaning that the word "substantially" implies. Vutek relies on the doctrine of claim differentiation, which creates a "rebuttable presumption that each claim in a patent has a different scope." Dow, 226 F.3d at 1341. Thus, limitations stated in a dependent claim ordinarily should not be read into the related...
independent claim. Id. Put another way, the inclusion of a specific limitation on a term in a dependent claim "makes it likely that the patentee did not contemplate the term … already contained that limitation." Phillips, 415 F.3d at 1324.

Applying this doctrine to the '518 Patent claims, Vutek argues that the use of "substantially cure" in claim 1 and "at least partially cure" in dependent claim 5 indicates that "substantially cure" must include "at least partially cure." While this may be true, I do not find that the phrase "at least partially cure," as it is used in the '518 Patent, alters the ordinary and customary meaning of "substantially cure."

Claim 5 reads as follows:

The method of claim 1 further comprising:

at least partially curing the ink jetted onto the surface by exposing the jetted ink to ultraviolet light and then heating the surface having the at least partially cured ink thereon to reduce the content of unpolymerized monomers of the ink on the substrate.

This claim refers to the use of a drying station to further cure the ink when printing on certain substrates, particularly fabrics. Although claim 5 does not explicitly reference fabric substrates, a person of ordinary skill in the art would recognize that the claim derives from Codos' own prior art, U.S. Patent No. 6,312,123 (the '123 Patent).

The '123 Patent, which is expressly incorporated into the '518 Patent, covers a method and apparatus for printing UV curable ink on fabrics such as mattress covers, comforters, and bedspreads. As the '123 Patent specification explains, due to the textured surface of fabric substrates, "UV light proceeds to cure only about 90%, or 97%, and can be even up to about 99% of the ink when deposited on fabric. However, if more than an order of magnitude of approximately 100 parts per million (PPM) (0.01%) of the total volume of jetted ink remains uncured, persons sensitive to the uncured monomers can suffer reactions." Thus, the '123 Patent, like claim 5 of the '518 Patent, teaches the use of a drying station to further cure ink on a fabric substrate before it is ready for its intended use. 5

--- Footnotes ---

5 In fact, the '518 Patent copies, almost verbatim, the paragraph from the '123 Patent specification discussing the use of the drying station. Compare '123 Patent, Col. 5:21-34 with '518 Patent, Col 8:51-65.

--- End Footnotes ---

Throughout the '123 Patent, "partially cured jetted ink" is defined as ink which is 90 to 97% cured, or polymerized. The '518 Patent incorporates this understanding of "partial cure" into its specification where it states, "[w]ith a 97% cure, the ink will be sufficiently colorfast so as to permit the drying station to be off-line." Thus, based on the specifications of the '123 and '518 Patents, I find that the phrase "at least partially cure" in claim 5 refers to a high level of cure that would fall within the scope of the ordinary and customary meaning of "substantially cure." In sum, even if "substantially cure" includes "at least partially cure," this fact does not indicate that the drafters of the '518 Patent used "substantially cure" in a manner inconsistent with the phrase's ordinary and customary meaning.

For foregoing reasons, I conclude that a person of ordinary skill in the art would interpret the phrase "substantially cure" to mean "to a great extent or almost completely cured." This level of cure includes the 90 to 97% "partial cure" discussed in the '123 and '518 Patent specifications that must be subjected to additional curing, as well as other levels of cure that render a substrate fully usable for its intended purpose.

3879

2. Defining an inner and outer portion

The next disputed term requires me to define "define," a term which arises throughout the patent. As Tyco noted at argument, the term is strongly linked to the nature of the channel itself, i.e., whether it must be a unitary channel or whether
the invention comprises a multi-channel embodiment. As already noted, claim 1 teaches

An absorbent article comprising:

a. an absorbent; and

b. a channel positioned inward from and along at least a portion of an edge of such absorbent, said channel substantially defining in said absorbent an inner portion and an outer portion, wherein the density of said absorbent in said inner portion is greater than the density of said absorbent in said outer portion.

(6:32-40.)

K-C argues that "defines" means "distinguishes," such that we would say the channel distinguishes one portion of the absorbent from the other. Tyco prefers a narrower construction, arguing that when the channel "defines" an inner and outer portion it means it separates the two portions by completely encircling the napkin, as shown in the figure on the first page of the patent, as well as in Figure 1. (Figures 2 and 3 are cross-sections presumably reflecting the same.) Tyco argues that this is the only interpretation that makes sense if the invention is designed (as the specification states) to wick fluid along the channel to "desorb" into unsaturated portions of the inner absorbent. (5:36-40.) That is, in Tyco's view if the channel does not form a complete circle, the intended distribution of fluid will not occur.

There is no support, however, for Tyco's attempt to limit the patent's claims in this fashion. In fact, its effort seems a classic attempt to import a limitation from the specification into the claims themselves, a maneuver the Federal Circuit universally rejects unless the specification evinces a clear intent to limit a claim or to specially define the meaning of the term. Phillips, 415 F.3d at 1316. This is especially true when the proposed limitation comes from a single embodiment of the invention; here, the specification merely states, "[d]esirably, the channel 22 is positioned inward . . . and completely encircles the inner portion of the absorbent 14." (4:55-58.) The specification makes clear that this is just one (albeit desirable) way in which the invention may be implemented, and nowhere else does the specification or claims indicate that complete encirclement is a required limitation. In fact, review of the claims themselves makes this clear. Claim 1, for instance, describes a "channel positioned inward from and along at least a portion of an edge of said absorbent," which suggests that some portion of the edge could not be accompanied by any channel. Had the claim said "along the entire edge" or even just "along the edge," it might be inferred that the channel must completely encircle the napkin. Because it does not, the claim itself suggests complete encirclement is not an intended limitation.

In addition, the claim states that the channel "substantially define[s]" an inner and outer portion. In other words, it serves as the distinguishing line of demarcation between the two portions of the napkin, and this can be accomplished whether the channel completely encircles the napkin or whether it merely "substantially" or mostly encircles it. As the Federal Circuit has noted, "the term 'substantially' is a descriptive term commonly used in patent claims to "avoid a strict numerical boundary to the specified parameter." Ecolab, 264 F.3d at 1367 (quoting Pall Corp. v. Micron Seps., 66 F.3d 1211, 1217 (Fed. Cir. 1995)). "In this case," the Ecolab court concluded, "'substantially' avoids the strict 100% nonuniformity boundary." To now conclude that the channel must completely encircle the napkin would be to allow one embodiment mentioned in the specification to trump the plain language of the claim itself. Tyco posits that the term "substantially" actually applies not to the horizontal definition of the inner and outer portions but to the vertical nature of the channel. In other words, it believes K-C used the term "substantially" to differentiate its invention from prior art whose grooves were not as deep and/or wide as its own invention; in that sense, "substantially" modifies the depth of the channels and not their level of horizontal encirclement. Yet there is little basis to accept this level of nuance in favor of the plain claim terms. The term "substantially defines" arises in the context of defining an inner and outer portion of the napkin, and these are horizontal concepts largely unrelated to the depth of the channel. Accordingly, in my view "substantially defines" means that the channel(s) serve to distinguish between the inner and outer portions, and in order to do so the channel(s) need not connect or constitute a single channel unit.

Tyco protests that this construction would create definitional problems because of the difficulty in determining when a channel would substantially define an inner and outer portion. Although a completely encircling channel would clearly define the two portions, it asserts, the same is not true with respect to a "J" or omega-shaped channel. Tyco believes such designs could conceivably define two portions of a napkin, but when would one portion begin and the other end? It is true that my construction could lend itself to less clarity in application than the one Tyco prefers. But it is equally true that such
an issue is more appropriately handled at the infringement stage. If there are gaps in a multi-channel napkin, a jury may be asked to determine whether the channels substantially define the two portions or not. The fact that the result might differ case-to-case does not mean that the construction of the claim terms must bend to accommodate only the most easily-applied definition.

Aptar is the assignee of the '067 patent, entitled "Mounting Cup" and issued December 20, 1988. The patent is generally directed to the mounting cup portion of the valve assembly, designed to be crimped onto the top of an aerosol can. The claimed invention of the '067 patent provides an improved seal between the cup and the can by using a cup rim shape that is "substantially different" from the contour of the annular bead, but that conforms to the shape of the annular bead when crimped. Figures 5 and 8 are representative of the claimed invention. Figure 5 shows the mounting cup before it is placed on the aerosol can.

The improved inner region contour (41A) of the mounting cup is flattened so that the interior space (43A) has a substantially different shape than the annular bead (not shown in Figure 5). When the mounting cup is placed over the annular bead, the flattened inner region contour (41A) inhibits the complete reception of the annular bead into the interior space (43A).

Figure 8 shows a completed aerosol device, a fragment of the can being shown at 40 with an annular bead (44) to which the mounting cup is crimped.

The six claims at issue on appeal are 1, 4, 7, 10, 15, and 17. Claim 1 is representative:

1. An improved mounting cup for sealing with a container of an aerosol dispensing device, the container having an annular bead extending about an opening in the container with the annular bead having an inner surface contour, comprising in combination:

   a metallic mounting cup comprising a central area, a sidewall and a peripheral rim with said sidewall interconnecting said central area and said peripheral rim;

   said peripheral rim having an inner region contour being substantially different from the inner surface contour of the annular bead of the container for allowing only a portion of said inner region contour of said peripheral rim to contact the inner surface contour of the annular bead when said mounting cup is disposed upon the container;

   said inner region contour of said peripheral rim being deformed when said mounting cup is crimped to the annular bead of the container to reform said inner region contour of said peripheral rim to be substantially the same as the inner surface contour of the annular bead to provide a seal engagement between said mounting cup and the container, and said crimping of said mounting cup to the annular bead of the container being accomplished solely by an outward radial expansion of said sidewall of said mounting cup to reform said inner region contour of said peripheral rim to be substantially the same as the inner surface contour of the annular bead to provide said sealing engagement between said mounting cup and the container.

Aptar filed an action against Summit alleging patent infringement. A jury trial ensued. The jury failed to reach a verdict on the '067 patent infringement liability issues. The parties submitted the liability issues to the court on the existing record. The court heard evidence relating to damages. The court found damages based on royalty damages of $ 0.75 per thousand devices ($ 3.9 million). It found willfulness and doubled damages to approximately $ 7.8 million. It later awarded pre-judgment interest of approximately $ 762,000. The court declined to award attorney fees or lost profits to Aptar. This appeal and cross-appeal followed.

ANALYSIS

I. Infringement

A literal infringement determination involves two steps. First, we determine the scope of the right to exclude by determining
the metes and bounds of the claim and, second, the properly construed claim is compared with the accused device to determine whether all of the claim limitations are present. Young Dental Mfg. Co. v. Q3 Special Prods., Inc., 112 F.3d 1137, 1141, 42 U.S.P.Q.2D (BNA) 1589, 1592 (Fed. Cir. 1997).

We review a district court's judgment for errors of law and clearly erroneous findings of fact. Fed. R. Civ. P. 52(a). Claim construction is a question of law, which we review de novo. Markman v. Westview Instruments, Inc., 52 F.3d 967, 976, 34 U.S.P.Q.2D (BNA) 1321, 1326 (Fed. Cir. 1995) (in banc), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996); Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (in banc) ("We review claim construction de novo on appeal including any allegedly fact-based questions relating to claim construction."). Whether a properly construed claim reads on an accused device is a question of fact.

A. Claim Construction

When construing a claim, a court should first look to the plain language of the claims and then consult the evidence intrinsic to the patent, namely the written description and the prosecution history. See Vitronics Corp. v. Conceptronics, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2D (BNA) 1573, 1576-77 (Fed. Cir. 1996). At issue in this case is the construction of the phrases "annular bead" and "substantially different."

The district court concluded that the claims were "plain and unambiguous, in light of the specification, drawings, and prosecution history of the patent", and, further, that "the parties did not submit evidence to dispute the meaning of any claim terms." The court also stated that "further claim construction beyond that stated in this court's summary judgment opinion is not required." In the summary judgment opinion, the court stated that:

The key feature of the '067 patent is that the inner region contour of the mounting cup peripheral rim is different in shape from the annular bead of the aerosol container. During crimpling, the peripheral rim's inner contour is deformed and reformed to match the shape of the annular bead of the container. . . . The parties agree that the inner region contour is defined as "the region of the curl of the mounting cup between the apex and the 'three o'clock' position of the uncrimped cup."

Contrary to Summit's position, the court did not overlook claim construction, it merely focused in on the characteristics relevant to infringement; the two determinations are inextricably intertwined.

We conclude that the district court properly determined, based on the claim language, the written description, and the prosecution history, that the claims require a mounting cup that "exhibits a flattening in the inner region contour, an area depicted as between 12 o'clock and 3 o'clock in Figures 4-11 of the '067 patent," wherein the "flattening extends substantially into the semi-circular region defined by the peripheral rim of conventional prior art mounting cups illustrated in Figures 1-3 of the '067 patent." The district court also concluded that the claimed cup must "not match the bead in that location before crimping . . . [and that the cup] when placed on can beads, does not fully seat on the can bead before crimping, but rather rests on the can bead in a manner resulting in a gap between the apex of the mounting cup and the apex of the can bead." In sum, the district court interpreted the claim to require a "flattening" sufficient to prevent the rim from properly seating on the annular bead, and creating a gap between the rim apex and the bead apex.

Not surprisingly, Aptar advocates this interpretation. Summit argues that this interpretation is in error because it fails to construe the requirement that the inner region contour be "substantially different" from the can beads, and instead relies solely on a "gap test", i.e., a gap existing between the apex of the mounting cup and the apex of the can bead. According to Summit, a proper interpretation must identify "how different a mounting cup inner region contour must be from a bead contour to meet the requirement that it be 'substantially different.'" We disagree. The district court determined this issue when it deemed that the flattening must merely be sufficient to prevent the rim from properly seating.

Summit further contends that the written description acknowledges that prior art mounting cups and can beads have "nominal variations" which are within quality control limits. Therefore, Summit contends that the term "substantially" should be limited to gaps that are much greater than the differences attributable to nominal manufacturing variations. However, the claims require that the shape of the inner surface contour be substantially different at a particular point (the inner region of the rim), intentionally creating a gap at a particular point (between the bead apex and the rim apex). That the prior art occasionally exhibited deviations at different places along the rim due to uncontrollable manufacturing effects does not require that the claims be limited to an intentional deviation at a particular point that extends further than any prior art
unintentional deviation.

Further, none of the prior art "tolerance ranges" pointed to by Summit concern the size of gaps between the apex of the annular bead and the apex of the peripheral rim as required by the claims. Summit's data merely addresses variations in the inside and outside diameters of the beads and, according to Summit, "bead height." Summit's argument requires drawing numerous inferences from this data, such as the size of gaps between the bead apex and peripheral rim apex in the prior art. There is no evidence that the prior art exhibited deviations only at the "inner contour region" of the peripheral rim sufficient to cause a gap between the apex of the bead and the apex of the rim.

AITH sued Hageman for infringement of its '417 patent asserting the following claims:

1. An advertising device for a golf cup comprising:
   a) a golf cup;
   b) a substantially doughnut-shaped annular ring member having a center opening and having an external peripheral portion dimensioned to co-axially fit into said golf cup; and advertising display means coupled to said ring member for displaying an advertisement visible to a golfer when adjacent to said golf cup.

9. A method for displaying an advertisement in a golf cup comprising the steps of:
   a) providing a substantially doughnut-shaped ring member which coaxially fits into a conventional golf cup;
   b) providing an advertisement on said ring member; and inserting said ring member into a golf cup.

In construing these two claims, the district court found that the critical claim limitation involved in the dispute was "substantially doughnut shaped." The district court concluded that "substantially doughnut-shaped" means a toroidal object, which is defined as a surface generated by a plane closed curve rotated about a line lying in the same plane as the curve but not intersecting it. The district court found that the accused Hageman device is a flat piece of light rectangular flexible plastic that, when rolled into a cylinder, snaps into the side of a modified golf cup to provide an advertising surface.

Because the district court found that the Hageman device is cylindrical and not doughnut-shaped or toroidal, it concluded that no reasonable jury could find that the Hageman device literally infringes either asserted claim of the '417 patent. Under a doctrine of equivalents analysis, the district court concluded that although both devices performed substantially the same function with substantially the same result, no jury could reasonably find that Hageman's device performed in substantially the same way as the claimed invention of the '417 patent. The district court found no infringement under the doctrine of equivalents despite the assertion by Mr. Enlow, AITH's patent expert, that the '417 patent was a pioneering invention deserving a greater range of equivalents.
AITH first suggests that the term "substantially doughnut-shaped" is unnecessary surplusage when the claims are read in light of the specification. At most, AITH argues, when reviewing the specification, this claim limitation should be defined more liberally to include simply a ring-shaped or circular object. Under this definition, AITH asserts, Hageman's cylindrical device would infringe claims 1 and 9 of the '417 patent. We agree with the district court, however, that a more limited definition of "substantially doughnut-shaped" is required.

We review the district court's claim interpretation de novo. See Markman v. Westview Instruments Inc., 134 L. Ed. 2d 577, 116 S. Ct. 1384, 1387, 38 U.S.P.Q.2D (BNA) 1461, 1463 (1996) (claim construction is exclusively within the province of the court). Both claims at issue specifically call for a substantially doughnut-shaped ring member. In construing a claim, we cannot ignore a limitation of the claim. See Warner-Jenkinson Co. v. Hilton Davis Chemical Co., 137 L. Ed. 2d 146, 65 U.S.L.W. 4162, 4165 (1997) (each element in a patent claim is material to defining the scope of the patented invention); United States v. Adams, 383 U.S. 39, 48-49, 15 L. Ed. 2d 572, 86 S. Ct. 708 (1966) (claims limit an invention and the specification cannot be utilized to expand the patent monopoly). Although the district court did not need to introduce the term toroidal to define "substantially doughnut-shaped," we agree with the district court that the accused Hageman device does not literally meet this claim limitation.

The Court construes "conduit" in its ordinary and customary sense, thus signifying a tube or channel for carrying or taking materials from one place to another. Random House Webster's College Dictionary at 275. In addition, the Court construes "guide" in its ordinary meaning, thus signifying something that helps to direct an object's travel or its progressive motion.

Turn-Key argues that this part of Element (d) must be construed to require that the process described above "form[s] a substantially enclosed guide conduit by the configuration or shaping of the mold parts." Joint Statement at 8. Defendants argue that this portion of Element (d) requires that "the motion of the two mold parts brings into existence a substantially enclosed guide conduit, which does not exist when the mold is closed." Joint Statement at 29; Crest's Responsive Brief at 11; KM, MC, & Concord's Brief at 6. The Court construes this portion of the claim language to signify that the result of the process of bringing apart the molds in the fashion described in the previously discussed claim language is a substantially enclosed conduit. The separation of the mold parts thus results in something-the conduit—that was not there when the mold parts were in the process of being brought together.

Turn-Key argues that the phrase "substantially enclosed guide conduit" must be construed as "a passageway through which the molded product is guided and transported that is formed within and substantially enclosed by the surfaces of the two mold parts." Joint Statement at 9. Defendants argue that this phrase must be construed as "a duct or channel for conveying material" and that the insertion of the term "guide" means that the conduit "directs the motion of material that passes through it, including molded plastic products as set forth below, thus determining, at least in part, the path of such material." Joint Statement at 29.

The Court construes "conduit" in its ordinary and customary sense, thus signifying a tube or channel for carrying or taking materials from one place to another. Random House Webster's College Dictionary at 275. In addition, the Court construes "guide" in its ordinary meaning, thus signifying something that helps to direct an object's travel or its progressive motion. Id. at 577. The Court consequently construes the "guide conduit" to be a tube or channel that carries materials from one place to another and that helps to direct the materials' progressive motion. The Court rejects Turn-Key's argument that the construction of the "guide conduit" as helping to direct the travel of the molded plastic product here in Claim 1 renders Claim 2 which specifically requires the orientation of the molded plastic product to be directed by the contours of the "guide conduit" superfluous. Claim 1 is an independent claim which merely introduces the guide conduit and Claim 2, a dependent claim, describes the guide conduit's role in one of the steps of the patented process. It is inconsistent for Turn-Key to concede that the guide conduit plays a role in directing the molded plastic product's orientation on the one hand and then to reject a definition of the conduit taking that role into consideration on the other hand.

--- Footnotes ---

5 During oral argument, counsel for Crest requested that the Court construe "guide conduit" to be a tube or channel that carries materials from one place to another and that solely helps to direct the materials' progressive motion. The Court, however, rejects this position because it is ultimately based upon Defendants' mistaken belief that the '998 patent cannot be used with the auxiliary parts that Sorensen criticized in the abstract and Objects of the Invention sections of his patent. This
The primary dispute in this case focuses on the construction of the term "guide conduit" found in limitation (d) of claim 1. In such cases, "where the parties do not dispute any relevant facts regarding the accused product . . . but disagree over possible claim interpretations, the question of literal infringement collapses into claim construction and is amenable to summary judgment." General Mills, Inc. v. Hunt-Wesson, Inc., 103 F.3d 978, 983 (Fed. Cir. 1997) (citing Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1578 (Fed. Cir. 1996)). In its claim construction ruling, the district held that the "substantially enclosed guide conduit" is "a tube or channel that is almost entirely closed in from the outside environment, and that carries materials from one place to another and that helps to direct the materials' progressive motion." The district court later clarified its claim construction, holding that "the guide conduit itself nevertheless must help to carry and direct the molded product's progressive motion." Based on that modified construction, the district court granted defendants' motions for summary judgment of non-infringement, concluding that the guide rails, kicker plate, and discharge chute of the CD-94 mold do not comprise a guide conduit as construed by the court.

We hold that the district court erred in its interpretation of guide conduit. A review of the claim language, written description, and prosecution history show that a guide conduit is simply a passageway through which a plastic product is moved. The plain language of the claims describes the guide conduit as an area within the mold. The district court's definition attributes a function to the guide conduit, namely that it direct the material's motion. That is an added limitation.
C. Claim Construction

1. The "Substantially Enclosed" Limitation

Semitool argues that the phrase "substantially enclosed" simply refers to the ability to contain processing fluids within the head and the bowl depending upon the processing fluid used, and that it distinguished the prior art (i.e., the Aigo reference) on that ground during prosecution. Semitool contends that the district court erred by requiring that the head and the bowl form a "seal," as the specification of the '708 demonstrates that a seal is required only in a preferred embodiment of the invention.

Novellus responds that the only embodiment of the claimed wafer processing tool set forth in both patents has a processing chamber that is sufficiently sealed to allow pressurization and to prevent ambient air flow into the chamber, and that the phrase "substantially enclosed processing space" must therefore be limited to that embodiment. Novellus also argues that Semitool limited its claims during prosecution to require that the wafer processing tool be sufficiently "sealed" to enable effective gas processing. Finally, Novellus contends that Semitool's process-dependent interpretation of the "substantially enclosed" limitation relies entirely on extrinsic evidence and has no support in the intrinsic record.

In interpreting claims, a court "should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification, and, if in evidence, the prosecution history." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2d (BNA) 1573, 1577 (Fed. Cir. 1996). When the meaning of a term used in a claim is sufficiently clear from its definition in the patent specification, that meaning shall apply. Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1477, 45 U.S.P.Q.2d (BNA) 1429, 1432 (Fed. Cir. 1998); Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388, 21 U.S.P.Q.2d (BNA) 1383, 1387 (Fed. Cir. 1992). Furthermore, "the prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1676 (Fed. Cir. 1995) (citations omitted).

We agree with Novellus that the district court properly construed the "substantially enclosed processing space" limitation to require a "seal" created by the head and the bowl that is sufficiently closed to permit the effective gas processing of a wafer using the gas phase of a processing fluid. Nothing in the plain language of the claims sheds any light on the meaning of the phrase "substantially enclosed." However, during the prosecution of the '310 patent, Semitool explained the significance of the "substantially enclosed" limitation when it distinguished the Aigo prior art reference, stating that:

[Claim 1] has been amended to recite that the complementary processing head and processing base define a substantially enclosed processing space when in the closed relative position. This allows the processing space to contain the gaseous or liquid processing chemicals. The Aigo reference has no ability to enclose the wafer and cannot process effectively using gases."  

'310 patent file history, Paper No. 8 at 5 (emphasis added). Although Semitool argues that it only disclaimed coverage for wafer processing tools that process wafers outside of the region defined by the head and the bowl, that interpretation would require us to ignore its statement requiring the tool to be capable of effective gas processing -- a statement that is divorced from any concept of "containing" the wafer and processing chemical in any particular processing space. We therefore find that Semitool expressly disclaimed coverage under the '308 patent of any wafer processing tool that cannot effectively utilize the gas phase of a processing chemical. See Southwall, 54 F.3d at 1576, 34 U.S.P.Q.2D (BNA) at 1676.

We reach the same conclusion with respect to the "substantially enclosed" limitation in the '708 patent. "When multiple patents derive from the same initial application, the prosecution history regarding a claim limitation in any patent that has issued applies with equal force to subsequently issued patents that contain the same claim limitation." Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 980, 52 U.S.P.Q.2d (BNA) 1109, 1114 (Fed. Cir. 1999) (citing Jonsson v. The Stanley Works, 903 F.2d 812, 817-18, 14 U.S.P.Q.2d (BNA) 1863, 1863-69 (Fed. Cir. 1990)). Thus, Semitool's relinquishment of subject matter during prosecution of the '310 patent applies with equal force to the '708 patent.
Moreover, the specification of the '708 patent expressly defines the "substantially enclosed" limitation as follows:

    The head 12 is loaded with wafer 20 which is held in position by the wafer holder. The head is positioned in sealing relationship with the bowl 14 or otherwise suitably adjusted to confine the processing chamber against drafts and other substantial leakages which might affect the homogeneous vapor phase which is being presented for contacting and etching the processed surface of the wafer 20.

'708 patent, col. 9, ll. 32-39 (emphasis added). We have repeatedly stated that "claims must be read in view of the specification . . . . Usually, it is dispositive; it is the single best guide to the meaning of a claim term." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577. Thus, although the claims of the '708 patent do not require an air-tight seal, the specification makes clear that they require a "seal" that is sufficient to prevent "drafts and substantial leakages" that might affect the ability of the processing chemical to operate in the gas phase. We therefore conclude that the district court correctly interpreted the "substantially enclosed" limitation in the '310 and '708 patents to require a "seal" created by the head and the bowl that is sufficiently closed to permit the effective gas processing of a wafer using the gas phase of a processing fluid, regardless whether the chemical to be used is in a gas or liquid state.

1. The "Substantially Enclosed" Limitation

Semitool argues that the phrase "substantially enclosed" simply refers to the ability to contain processing fluids within the head and the bowl depending upon the processing fluid used, and that it distinguished the prior art (i.e., the Aigo reference) on that ground during prosecution. Semitool contends that the district court erred by requiring that the head and the bowl form a "seal," as the specification of the '708 demonstrates that a seal is required only in a preferred embodiment of the invention.

Novellus responds that the only embodiment of the claimed wafer processing tool set forth in both patents has a processing chamber that is sufficiently sealed to allow pressurization and to prevent ambient air flow into the chamber, and that the phrase "substantially enclosed processing space" must therefore be limited to that embodiment. Novellus also argues that Semitool limited its claims during prosecution to require that the wafer processing tool be sufficiently "sealed" to enable effective gas processing. Finally, Novellus contends that Semitool's process-dependent interpretation of the "substantially enclosed" limitation relies entirely on extrinsic evidence and has no support in the intrinsic record.

In interpreting claims, a court "should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification, and, if in evidence, the prosecution history." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1577 (Fed. Cir. 1996). When the meaning of a term used in a claim is sufficiently clear from its definition in the patent specification, that meaning shall apply. Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1477, 45 U.S.P.Q.2D (BNA) 1429, 1432 (Fed. Cir. 1998); Intellitec, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388, 21 U.S.P.Q.2D (BNA) 1383, 1387 (Fed. Cir. 1992). Furthermore, "the prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1676 (Fed. Cir. 1995) (citations omitted).

We agree with Novellus that the district court properly construed the "substantially enclosed processing space" limitation to require a "seal" created by the head and the bowl that is sufficiently closed to permit the effective gas processing of a wafer using the gas phase of a processing fluid. Nothing in the plain language of the claims sheds any light on the meaning of the phrase "substantially enclosed." However, during the prosecution of the '310 patent, Semitool explained the significance of the "substantially enclosed" limitation when it distinguished the Aigo prior art reference, stating that:

[Claim 1] has been amended to recite that the complementary processing head and processing base define a substantially enclosed processing space when in the closed relative position. This allows the processing space to contain the gaseous or liquid processing chemicals. The Aigo reference has no ability to enclose the wafer and cannot process effectively using gases."
'310 patent file history, Paper No. 8 at 5 (emphasis added). Although Semitool argues that it only disclaimed coverage for wafer processing tools that process wafers outside of the region defined by the head and the bowl, that interpretation would require us to ignore its statement requiring the tool to be capable of effective gas processing -- a statement that is divorced from any concept of "containing" the wafer and processing chemical in any particular processing space. We therefore find that Semitool expressly disclaimed coverage under the '308 patent of any wafer processing tool that cannot effectively utilize the gas phase of a processing chemical. See Southwall, 54 F.3d at 1576, 34 U.S.P.Q.2D (BNA) at 1676.

We reach the same conclusion with respect to the "substantially enclosed" limitation in the '708 patent. "When multiple patents derive from the same initial application, the prosecution history regarding a claim limitation in any patent that has issued applies with equal force to subsequently issued patents that contain the same claim limitation." Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 980, 52 U.S.P.Q.2D (BNA) 1109, 1114 (Fed. Cir. 1999) (citing Jonsson v. The Stanley Works, 903 F.2d 812, 817-18, 14 U.S.P.Q.2D (BNA) 1863, 1863-69 (Fed. Cir. 1990)). Thus, Semitool's relinquishment of subject matter during prosecution of the '310 patent applies with equal force to the '708 patent.

Moreover, the specification of the '708 patent expressly defines the "substantially enclosed" limitation as follows:

The head 12 is loaded with wafer 20 which is held in position by the wafer holder. The head is positioned in sealing relationship with the bowl 14 or otherwise suitably adjusted to confine the processing chamber against drafts and other substantial leakages which might affect the homogeneous vapor phase which is being presented for contacting and etching the processed surface of the wafer 20.

'708 patent, col. 9, ll. 32-39 (emphasis added). We have repeatedly stated that "claims must be read in view of the specification . . . . Usually, it is dispositive; it is the single best guide to the meaning of a claim term." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577. Thus, although the claims of the '708 patent do not require an air-tight seal, the specification makes clear that they require a "seal" that is sufficient to prevent "drafts and substantial leakages" that might affect the ability of the processing chemical to operate in the gas phase. We therefore conclude that the district court correctly interpreted the "substantially enclosed" limitation in the '310 and '708 patents to require a "seal" created by the head and the bowl that is sufficiently closed to permit the effective gas processing of a wafer using the gas phase of a processing fluid, regardless whether the chemical to be used is in a gas or liquid state.

13. "said unscrambling means is substantially entirely on a user replaceable card"

The plaintiff contends this term needs no construction. Defendant EchoStar argues that the term is indefinite under 35 U.S.C. § 112, P 2 because it provides that some undefined amount of circuitry or degree of functionality of the unscrambling means is located on a card replaceable by the user. The DIRECTV defendants argue that the term means the entire unscrambling means is located on the user exchangeable unscrambling card.

As discussed in Part III.B.12 above, the specification makes clear that in certain embodiments it is the user card and the decoding box acting together which accomplish the task of unscrambling. '066 Patent, col. 4, lines 14-24. Consequently, I reject the construction proposed by the DIRECTV defendants.

Nor do I find that the term "substantially entirely" is indefinite to one skilled in the art when read in the context of the rest of the specification. The specification makes clear that in some embodiments the entire circuitry for the unscrambling circuit would be on the user card, '066 Patent, col. 3, lines 62-68, while in other embodiments the decoding box and the user card would each contain various parts of electronic circuits which would act together to provide the unscrambling. Id. at col. 4, lines 14-19. And as I previously have explained, the unscrambling means works in such a way that when one user card is activated, that card's circuitry replaces the circuitry of any other user card for use in the unscrambling means. In this context, I agree with the plaintiff that the term "substantially entirely" is not indefinite and needs no further construction.
With respect to the "substantially entirely and flushly" limitation of claim 1, although defendant asserts that its product has no corresponding structure matching those limitations, it does not suggest a construction of that phrase. As with the majority of the patent terms interpreted here, plaintiff has not offered a proposed construction, and nothing in the patent indicates that plaintiff intended to assign to those terms definitions other than those by which they are customarily understood. Thus, the court construes those terms in light of their plain and ordinary meaning.

Webster's defines "substantially," the adverbial form of "substantial," as "being largely but not wholly that which is specified." Webster's Collegiate Dictionary 1174 (10th ed. 1999). "Entirely" is defined as "to the full or entire extent: completely." Id. at 387. "Flushly," the adverbial form of "flush," is defined as "having or forming a continuous plane or unbroken surface." Id. at 449. Thus, the court construes the phrase "substantially entirely and flushly" as requiring the lid's latch bar to fit within the recess formed across the tongue in a manner that creates an almost completely continuous plane with the outer, front side of the container.

8. "substantially envelopes"

In accordance with the Court's construction of "coating layer" as "a layer of material that substantially surrounds, encases or encapsulates the cords, and defines an engagement surface for engaging a sheave," it follows that "substantially envelopes" means "substantially surrounds, encases or encapsulates." 6

6 Schindler argues that "substantially enveloping" should mean "fully encasing or encapsulating; completely surrounding at least around the circumference [of the cords]." Although the preferred embodiments show fully encased cords, the patent's scope need not be so limited. See Kara Technologies Inc. v. Stamps.com Inc., 582 F.3d 1341, 2009 U.S. App. LEXIS 21120, at *13 (Fed. Cir. Sept 24, 2009). The term "substantially" is not equivalent to "completely." The plain meaning of "substantially enveloping," then, does not indicate that the cords must be completely encased by the coating layer in every possible embodiment of the invention.

2. '669 Patent: "Substantially Equal"

Claim 1 of the '669 patent includes the limitation that "the change in exhaust temperature . . . is substantially equal to the change in temperature rise of a typical one of said heat-generating elements over said range of air flow rates." '669 patent, col.6, ll.28-33. Delta argued that "substantially equal" simply means "nearly the same." Markman Hr'g Tr. at 23:7-8. Control again adopted a more functional approach. Both in its papers and at oral argument, Control asserted that "substantially equal" is not limited to a specific value or an exact equality of temperature changes. Pl.'s Opp'n at 17; Markman Hr'g Tr. at 25:1-5. Instead, Control asserted that "substantially equal" refers to the difference in temperature rise necessary to maintain a semiconductor junction at a nearly constant temperature.

There is nothing in the claim or written description, however, that suggests that "substantially equal" should be given anything other than its ordinary meaning. The goal of the patent is to maintain the heat-generating elements at a nearly constant temperature. The patent teaches that to achieve this, the difference in temperature rise exhibited by a typical semiconductor is nearly the same as the difference in exhaust temperature. '669 patent, col.5, ll.6-12. Indeed, the example provided in the patent uses the numerical quantity of three degrees to describe the "match" in temperature changes. Id. col.5,
ll.8-9. According to the prosecution history, this "critical matching . . . is at the heart of [the] invention." Katz Decl. Ex. D at C00124. Control's claim construction essentially wipes out the "substantially equal" language in favor of a functional test that simply asks whether the heat-generating elements are maintained at a nearly constant temperature, regardless of the means employed to achieve that goal.

Ultimately the Court construed "substantially equal" as "nearly the same." Markman Hr'g Tr. at 31:18. The Court then contextualized its definition in the form of a proposed address to the jury:

But you have to keep in mind what we are comparing here. That means, that substantially equal means nearly the same and what it requires, what it claims here is a relationship between the difference in temperature rise of a typical semiconductor and the temperature range of the exhaust air.

Id. at 31:18-23.

3891

4. "[T]he thickness is substantially equal on the left side region of the second zone and the right side region of the second zone." Used in '753 patent, claim 15.

CooperVision proposes "the second zone includes a series of cross-sections that each has a substantially uniform thickness not varying by more than about 30 gm or 20% of the minimum thickness within the cross-section. The area of the second zone to the left of the vertical meridian has a thickness topography that is symmetric with a thickness topography of the area of the second zone to the right of the vertical meridian." CIBA contends "at any given horizontal cross-section, the thickness is approximately the same across the entire horizontal cross-section on the left side region of the second zone and the right side region of the second zone."

In their briefing to the court, the parties agreed that the relevant area of analysis is the entire inner or second zone, which excludes the optic and peripheral zone. The parties also agreed that substantial uniformity means no more than about 30 pm or 20%. See '903 patent, col. 7, ll. 22-30; col. 6, ll. 55-58. At the hearing, moreover, CooperVision agreed that in the horizontal direction, cross-sections must be substantially uniform. The remaining dispute, therefore, is whether the cross-sections must also be symmetrical so that every point on the left side is a mirror image of a point on the right side.

Claim 3 of the '753 patent shows that the patentee knew how to claim vertical symmetry and chose not to do so in claim 15. See '753 patent, claim 3 (requiring a lens thickness profile that "is symmetrical with respect to the vertical meridian"). Unlike claim 3, claim 15 requires only that regions of the left and right sides be "substantially equal." There is no reason to conclude that "substantially equal" in claim 15 is actually two limitations in one, and that it actually includes a symmetry requirement. CooperVision's construction inaccurately requires the thickness topography to be symmetrical.

The court defines this term as follows:

"[T]he thickness is substantially equal on the left side region of the second zone and the right side region of the second zone" means: the second zone includes a series of horizontal cross-sections each having substantially uniform thickness not varying by more than about 30 jm or 20% of the minimum thickness on the left side region and the right side region.

3892

2. The '236 Patent

Claims 1 and 16 of the '236 Patent read as follows:

1. A method of creating a construction block adapted to form retaining walls or the like, comprising the steps of:
(a) forming a member having a major upper surface and a major lower surface and a plurality of edges, said upper major surface having a ridge extending laterally across a midsection thereof between an opposed pair of said edges with said ridges extending upwardly and away from said upper major surface by a predetermined first dimension, said lower major surface having a notch extending laterally across a midsection thereof between said opposed pair of edges with said notch extending upwardly from said lower major surface by a dimension substantially equal to said predetermined first dimension, wherein said laterally extending ridge is parallel to and disposed vertically above said laterally extending notch; and

(b) splitting said member along a center of both said ridge and said notch to define a pair of said construction blocks, wherein each said construction block has rough textured front surface defined by splitting the member in half, a recess extending laterally thereunder, and a lip extending laterally thereover wherein the height of said lip is substantially equal to the depth of said recess.

16. The method of creating a construction block adapted to form retaining walls or the like comprising the steps of:

(a) preparing a mold box for receiving raw concrete with the mold box having opposed front and rear walls and opposed side walls and with the opposed lateral side walls having parallelly disposed horizontally aligned rectangular core bar receiving openings formed along the lower edges thereof;

(b) inserting an elongated rectangular core bar within said mold box extending between said parallelly disposed horizontally aligned openings for forming a notch;

(c) loading raw concrete within said mold box while forming cores within said raw concrete along a vertical axis normal to the axis of said core bar to form a member having a major upper surface and major lower surface and a plurality of edges, said major upper surface formed with a ridge; and

(d) splitting said member along a center of both said ridge and said notch to define a pair of said construction blocks, wherein each said construction block has rough textured front surface defined by splitting the member in half, a recess extending laterally thereunder, and a lip extending laterally thereover wherein the height of said lip is substantially equal to the depth of said recess.

The phrase "wherein the height of said lip is substantially equal to the depth of said recess" appears in claims 1(b) and 16(d) of the '236 Patent. Allan Block asserts that "substantially equal" is a commonly understood term and needs no further construction. To the extent that construction is warranted, Allan Block urges the following meaning: "The height of the block's lip must be equal to, or within some amount of deviation from, the depth of the block's recess. This limitation does not impose a strict numerical boundary on the relationship between the lip height and the recess depth." Allan Block further argues that whether the height of the block's lip is "within some deviation from" the depth of the block's recess presents a question of fact. County Materials contends that the phrase means that "the height of the lip must be substantially equal to the depth of the recess," wherein "substantially equal" means "equal to one another within 1/16th of an inch."

Claims 1 and 16 of the '236 Patent require, in part, that the block be created so that the dimensions of the lip and the recess are such that "the height of said lip is substantially equal to the depth of said recess." The parties agree that the term "substantially" is a word of approximation, commonly used in patent claims to avoid a strict numerical boundary to a specified parameter. See Anchor Wall Sys., Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1310-11 (Fed. Cir. 2003) ("[T]he ordinary meaning of the phrase 'generally parallel' envisions some amount of deviation from exactly parallel."); see also Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 907 (Fed. Cir. 2005). Here, "substantially" modifies the term "equal," thus allowing some amount of deviation from exactly equal. Nothing in the claim language requires a numerical limitation on the amount of deviation allowed.

The specification does not provide a special definition for the term "substantially" or the phrase "substantially equal." Nor does the specification place a strict numerical boundary on the relationship between the lip height and the recess depth. Instead, the specification provides a more general description of the relationship between, and the function of, the lip and the recess:

The back surface 52 of each lip 34 is smooth and vertical with respect to the upper major surface of block 40. Similarly, the vertical surface 54 of recess 48 is smooth as well and in combination with surface 52 provides for a tight fitting wall
system and fast installation.

'236 Patent, col. 5, ll. 56-61.

The width "W" of core bar 20 directly corresponds to this setback "A" defined when the blocks 40 are stacked, where front surface 54 of each recess 48 is securely abutted against the back surface 52 of the corresponding lip 34 of the block disposed thereunder.

Id. at col. 6, ll. 40-45.

When the blocks 70 are stacked such as shown in FIGS. 5 and 6, the tapered surfaces 74 and 78 of the corresponding recesses 76 and ridges 72, respectively, are conforming and abut one another.

Id. at col. 6, ll. 57-60.

The preferred method invention disclosed realizes retaining wall blocks with an upper forward lip and a lower front recess which provides creating a sound structure which is not susceptible to shifting once embedded in an embankment. Thus, shifting of the retaining wall blocks once integrated into a retaining wall is inhibited.

Id. at col. 7, ll. 19-24.

The Court looks next to the prosecution history. County Materials argues that because the "substantially equal" limitation was added during the prosecution of the '236 Patent, it should allow for no more than some very minimal deviation from "perfectly or exactly equal" and that it should be construed as "equal to one another within 1/16th of an inch." The Court disagrees. Although the "substantially equal" limitation was added during the patent's prosecution, nothing in the '236 Patent or statements made during its prosecution specifies a numerical limitation on the permissible deviation between the lip height and the recess depth. County Materials offers no evidence from the prosecution history supporting the imposition of the strict plus-or-minus 1/16th inch limitation. Instead, County Materials relies on extrinsic evidence, such as industry standards, expert testimony, and Allan Block's production standards to support its argument that the lip height and the recess depth must be "equal to one another within 1/16th of an inch." The Court declines to consider this evidence, however, because the intrinsic evidence does not support construing "substantially equal" to require a strict numerical limitation on the relationship between the lip height and the recess depth. 3 See Playtex, 400 F.3d at 909.

--- Footnotes ---

3 Even if the Court were to consider County Materials' extrinsic evidence, the Court would reach the same result. The ASTM Industry Standards relied on allow for a permissible deviation of 1/8th inch for a block's overall dimensions for width, height, and length. Moreover, while Allan Block's production control standards require that each block used in a particular project vary by no more than 1/16th inch, it refers to a block's overall height. There is no evidence that either of these standards apply to the height of the lip or the depth of the recess.

--- End Footnotes ---

Consistent with the claim language, the specification, and the prosecution history, the Court determines that the claim language creates no ambiguity and has a readily understood meaning. Accordingly, the Court declines to construe the phrase "wherein the height of said lip is substantially equal to the depth of said recess." GO BACK

3893

7. Substantially exclusively

FieldTurf's Proposed Construction: "almost entirely"

SCG's Proposed Construction: "entirely"
The Court's Claim Construction: "almost entirely"

"Substantially exclusively" is used in claim 1 to describe the composition of resilient particles in the top course. Fieldturf points out that the same language is used in the specification, '689 patent, 10:20-21, and cites authority to the effect that "substantially" is a common term of approximation used in patent claims. E.g., Verve, LLC v. Crane Cams, Inc., 311 F.3d 1116, 1120 (Fed. Cir. 2002).

SCG does not point to anything in the specification that would support a definition of entirely, and instead acknowledges that substantially exclusively is used in the specification. '689 patent, 10:20-21. It then points to two dependent claims in each patent 16 which state that "particle sizes of 80% by weight of hard granules and resilient granules in the bottom course are distributed in a range spanning a particular screen mesh standard. '689 patent, cl. 8-9; '752 patent, cl. 9-10. It then posits that "[s]ince the top course is 'substantially exclusively of resilient rubber granules' it must contain at least greater than 80 percent resilient rubber granules." However, the quoted claim language has nothing to do with a particular percentage of resilient granules being in the bottom course, but rather the percentage by weight of both hard and resilient granules being distributed in a particular size range in the bottom course. The cited claims are simply not relevant to the amount of resilient granules in the top course.

--- Footnotes ---

16 SCG draws the court's attention to claims 7 and 8, but neither patent has the described limitation in claims 7 and 8. Rather the described limitation is in claims 8 and 9 of the '689 patent and claim 9 and 10 of the '752 patent.

--- End Footnotes ---

SCG next argues that "[n]o jury would be assisted by FieldTurf's proposed claim construction(s)" and that "[i]t is beyond the ken of reason to understand how a jury would use FieldTurf's definitions of 'predominantly' or 'almost entirely' to measure whether a layer includes a certain type of granules." However, as the Court noted above, FieldTurf correctly points out that the Court of Appeals for the Federal Circuit allows language of approximation. Accordingly, this latter argument is without merit.

GO BACK

3894

I. Term 10: "substantially fill the defect"

The Court construes the term "substantially fill the defect" in claim 17 of the '291 patent as follows:

A joining segment "substantially fills a defect" if the perimeter of the joining segment is substantially the same size as the perimeter of the defect.

Put simply, the parties' dispute over this term amounts to a disagreement over whether a hollow plug can fill a hole in the heart. AGA contends that claim 17 of the '291 patent requires a "joining segment" that "substantially fills" a defect by virtue of the segment's having "a physical cross-sectional area substantially equal to the cross-sectional area of the defect in order to stop the flow of blood through the defect." Am. JCCS Sched. B at 31-32. The University contends that this construction is too narrow. Univ. Opening Br. at 44.

The Court agrees with the University. The specification of the '291 patent discloses two very different embodiments of the patented device. In one embodiment, two flat disks are attached at their centers, and the resulting "conjoint disk" fills the defect to be closed. See '291 patent figs. 3-11. This device would be covered by claim 17 if the Court adopted AGA's proposed construction of the term "substantially fill the defect." The conjoint disk in this embodiment is flat and solid -- that is, it has a "cross-sectional area" roughly equal in size to the defect in which the conjoint disk is located.

In a second embodiment, however, the "joining segment" is hollow and results from the concentric assembly of two cylindrical projections at the center of the two disks. See '291 patent fig. 12; see also id. claim 9 (claiming "[t]he closure
device of claim 1 wherein the conjoint disk comprises a tubular segment"). Further, in this embodiment -- which the Court will call the "balloon-type" embodiment -- blood flow through the defect is not necessarily stopped by the joining segment alone (as would be required by AGA's proposed construction), but rather could be stopped because the hollow joining segment is attached on either side to membranes, and the membranes block the flow of blood. '291 patent col. 9:42-49. The joining segment and the attached membranes can also be filled with a liquid that then hardens to block blood flow. Id. col. 9:35-41. But in the balloon-type embodiment, the joining segment itself -- whether or not later filled with liquid -- is hollow. The joining segment does not have a "cross-sectional area" equal to the area of the defect, nor does the joining segment itself "stop the flow of blood through the defect."

The '291 patent clearly discloses the balloon-type embodiment, and clearly identifies the hollow segment at the center of that embodiment as a "tubular segment" that "is desirably sized to substantially fill the defect being blocked . . . ." '291 patent col. 9:16-19. In effect, in the balloon-type embodiment, the joining segment is like a hollow plug. And there is nothing unusual about saying that a hollow plug "fills" a hole. Under the circumstances, the Court construes the phrase "substantially fill the defect" to cover both preferred embodiments disclosed in the specification. See, e.g., Primos, Inc. v. Hunter's Specialties, Inc., 451 F.3d 841, 848 (Fed. Cir. 2006) ("[W]e . . . should not normally interpret a claim term to exclude a preferred embodiment.").

GO BACK

3895

4. "[S]ubstantially flat:" 6 "Thin and substantially uniform in thickness." This construction is consistent with the claims as well as the specification. The parties' disagreement concerns plaintiffs' proposed additional limiting language "having an overall profile that is substantially straight." Considering plaintiffs' proposed construction in the context of claim 27 of the '095 patent, which describes taking a substantially flat configurable dielectric separator and arranging it to form at least two grooves, would lead to the illogical result that the separator have "an overall profile that is substantially straight" after arranging it. The specification explicitly counsels against the result of plaintiffs' proposal, describing the pair separator in figure 6 as a "flat configurable tape used as a core filler, that is shaped to have the illustrated profile . . . ." (col. 6:12-15)

H. Substantially Flat and Substantially Flush

The Court finds that the terms "substantially flat" and "substantially flush" are unambiguous and therefore require no construction.

GO BACK

3897

3. "An upper surface which is substantially flat across the bottle retaining pockets"

Claims 1, 3, 19, 21, 23, 33, 39 and 56 of the '874 patent and Claim 7 of the '176 patent use the language for a case bottom that includes "an upper surface which is substantially flat across the bottle retaining pockets."

a. Norseman's Position

Norseman construes this limitation to require the upper surface of the case bottom to be continuously and substantially horizontal across the bottle retaining pocket. Motion, at 20-21.
b. Rehrig's Position

Rehrig argues that construction of the term "substantially flat" must be made in light of the patent's specification and drawings which show the surfaces to have multiple openings and recesses and are not relatively smooth and even. Rehrig also contends that the degree to which the surfaces may deviate from absolute flatness is indicated by the function of the surfaces as described in the specification. Namely, the bottle retaining pockets are meant to perform the functions of allowing retention of bottles without base indentations and permitting bottle rotation. Ex. 1, col. 3:61-64. Rehrig therefore argues for a construction of "substantially flat" that would allow any deviation from absolutely horizontal such that the surface was still able to perform these two functions.

Rehrig's construction is therefore:

"A pocket bottom with a relatively smooth or even surface at the bottle contact area, which may include small deviations from an even surface provided the bottle intended for the case may be easily rotated."

Opposition, at 23.

c. Court's Construction

As each of the parties point out in their briefs, the dictionary definitions of flat include: "having a continuous horizontal surface," "having a relatively smooth or even surface," and "having or marked by a continuous surface that is horizontal or nearly so, without significant curvature, without noteworthy elevations or depressions." Opposition, Ex. F; Websters Third New International Dictionary (1969). In light of the patent's specification, drawings, and the plain meaning ordinarily giving to the terms "substantially" and "flat," the Court declines to accept Rehrig's invitation to interpret this language to mean any pocket bottom with small deviations so long as the surface still performs the functions of retaining bottles without base indentations and rotation of bottles.

Such an interpretation merely shifts the construction question from the term "substantial" to the term "small deviations." In either event, the crucial question is the degrees of freedom away from horizontal afforded in this instance by the modifying term "substantial." The Court construes the language to allow deviations such as imperfections and inconsistencies on an otherwise continuous and horizontal surface. Therefore the Court construes this term to require a pocket bottom with a relatively smooth or even surface at the bottle contact area without significant curvature or noteworthy deviations from horizontal.

3898

The "Substantially Flat, Horizontally Disposed Bottom Wall" Limitation in Claim 1

Independent claim 1 of the '214 patent includes as a limitation a "substantially flat, horizontally disposed bottom wall." (filing no. 62, Ex. 1, claim 1) The parties dispute the meaning of the phrase "substantially flat." Trail King asserts that the court should construe the "substantially flat" limitation to mean "entirely flat." Circle R suggests that the court should construe the "substantially flat" limitation to mean "largely, but not wholly, flat." Circle R claims that the term "substantially flat" bottom wall should, therefore, include bottom walls having a slight curvature.

After examining the '214 patent's claim language, the patent specification, and the patent's prosecution history, the court holds that the "substantially flat" limitation in claim 1 should be construed to mean "entirely flat." This construction is supported by the fact that nowhere in the '214 patent is the bottom wall depicted as anything but completely flat. (See filing no. 62, Ex. 1) One skilled in the art on the application date would interpret the "substantially flat" wording to mean "entirely flat," rather than "slightly curvilinear." Indeed, a definition of "substantial" found in Webster's Third New International Dictionary is "being that specified to a large degree or in the main." Circle R's construction of the "substantially flat" language would seem to exclude those bottom walls that are completely flat and include only those bottom walls that have a slight curvature. However, if this was what the inventor meant when drafting the patent language, the language would have actually read "slightly curved, horizontally disposed bottom wall." This would have been a more direct way to describe a
bottom wall having a slight curvature. The prosecution history of the '214 patent supports this construction.

As noted above, the district court construed the claim term "substantially flat" to require that the bottom wall or bed of the trailer be "entirely flat" largely because the specification showed only embodiments that were, in the district court's view, entirely flat.

The district court's "entirely flat" claim construction was erroneous. We recognize that "claims must be read in view of the specification, of which they are a part." Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2d (BNA) 1321, 1329 (Fed. Cir. 1995), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996); but it is also well-established that, as a general rule, "words in a claim will be given their ordinary and accustomed meaning, unless it appears that the inventor used them differently." Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759, 221 U.S.P.Q. (BNA) 473, 477 (Fed. Cir. 1984) (internal quotations omitted). Here the "ordinary and accustomed meaning" of the word "substantially," as reflected in dictionary definitions, 3 as "considerable in . . . extent," American Heritage Dictionary Second College Edition 1213 (2d ed. 1982), or "largely but not wholly that which is specified," Webster's Ninth New Collegiate Dictionary 1176 (9th ed. 1983)." See also York Prods., Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1572-73, 40 U.S.P.Q.2d (BNA) 1619, 1622 (Fed. Cir. 1996) (construing "substantially the entire height" as "most of the entire height"); Amhil Enters., Ltd. v. Wawa, Inc., 81 F.3d 1554, 1562, 38 U.S.P.Q.2d (BNA) 1471, 1476 (Fed. Cir. 1996) (construing "substantially vertical" faces to mean "well-defined faces that deviate only slightly, if at all, from the vertical") (emphasis added). In other words, a claim term is not limited to the preferred embodiments, and "the specification here does not define any of the disputed claim language in a manner inconsistent with its ordinary meaning." Pall Corp., 259 F.3d at 1391. Thus, the district court erred when it concluded that the specification required the phrase "substantially flat" be construed to mean "entirely flat."

However, during the prosecution of the 214 patent the patentee confronted a rejection of claim 1 by the examiner because the prior art of U.S. Patent No. 4,494,798 (the "Bailey patent") showed a similar side dumping trailer body. The Bailey patent, among other things, specified a side dumping trailer body having a bottom wall that "comprises a section of an ellipse." Circle R I, slip op. at 5. The examiner accordingly rejected a number of Circle R's claims "as being anticipated by Bailey."

In response to that rejection, Circle R informed the examiner that "although applicant sincerely believes that claim 1, as originally presented, did define patentable subject matter, claim 1 has been rewritten as claim 6 with certain limitations added thereto to clearly distinguish Bailey." Circle R stated in pertinent part that:

Claim 6 now describes that the body of applicant's structure includes a substantially flat, horizontally disposed bottom wall . . . . The relationship which has been now described in claim 6 clearly distinguishes Bailey.

(emphasis added). The claim thus amended was allowed, and issued as claim 1 of the 214 patent.

Under these circumstances we conclude that "substantially flat" must mean that the bottom wall is flatter than Bailey. See Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2d (BNA) 1673, 1676 (Fed. Cir. 1995) ("Arguments and amendments made during the prosecution of a patent application and other aspects of the prosecution history . . . must be examined to determine the meaning of terms in the claims.") Bailey shows the bottom wall as indicated
by reference number 11 in Figure 4 as follows:

[SEE FIGURE 4 IN ORIGINAL]

The engineering drawing depicting the accused device clearly shows that the bottom wall of the allegedly infringing device is more curved than the bottom wall in the Bailey patent. Therefore, under our claim construction that "substantially flat" means flatter than the bottom wall in the Bailey patent, Circle R cannot establish literal infringement. So too the prosecution history forecloses Circle R's reliance on the doctrine of equivalents. Having narrowed the scope of the claim during prosecution for reasons related to patentability, Circle R cannot attempt to recapture the surrendered subject matter through the doctrine of equivalents. Festo Corp. v. Shoketsu Kinzoku Kogyo Kabushiki Co., 234 F.3d 558, 574 56 U.S.P.Q.2D (BNA) 1865, 1877 (Fed. Cir. 2000) (en banc), cert. granted, 150 L. Ed. 2d 692, 121 S. Ct. 2519 (2001) (No. 00-1543).

Under these circumstances we conclude that the grant of summary judgment, though based on an erroneous claim construction, was correct in result. 4

4 We note that neither Circle R's complaint, nor the district court's order, specified which claims of the 214 patent were alleged to be infringed. However, because the accused products concededly do not fall within the limitations of independent claim 1, the products also cannot infringe any of the other claims, which all depend from claim 1.

4. substantially flat surface

The term "substantially flat" appears in claims 1 - 24 of the '874 patent and claims 1 - 20 of the '786 patent. The plaintiff apparently proposes that the above term be construed in accordance with its plain and ordinary meaning. The defendant proposes a construction that excludes the presence of defined cavities within the surface. The defendant bases its construction on an amendment made by the patentees with respect to claims 2 and 3 of the '437 application. As stated by the patentees in their amendment,

[Opening Brief of the Plaintiff, Exhibit 8 at 7 (emphasis added).

"When multiple patents derive from the same initial application, the prosecution history regarding a claim limitation in any patent that has issued applies with equal force to subsequently issued patents that contain the same claim limitation." Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 980 (Fed. Cir. 1999) (citing Jonsson v. The Stanley Works, 903 F.2d 812, 817-18 (Fed. Cir. 1990). Although the '437 application was abandoned before issuance, claims 2 and 3 of the '437 application issued as claims 2 and 3 of U.S. Patent No. 5,823,782, which issued from a continuation application that was based on the '437 application. Therefore, the above portion of the prosecution history is relevant to the construction of this claim term. The court concludes, however, that the limitation "substantially flat" inherently excludes the defined cavities of Lee and that this term needs no further construction.

GO BACK

- 4558 -
1. Claim 1: "substantially flattened surfaces"

The district court determined that there was ambiguity in claim 1 which could not be resolved by the intrinsic evidence to warrant using extrinsic evidence in construing "substantially flattened surfaces." It concluded that the claim term "substantially flattened surfaces" had a plain meaning: "two opposing surfaces with a curvature less than either the barrel or the transitional portion of the prior art." However, with the evidentiary submissions by various experts relating to potential constructions of the disputed term, the district court concluded that if the term "substantially flattened surfaces" were construed to include curved surfaces, it would require exclusion of flat surfaces. The district court noted that the various figures representing the preferred embodiment contained in the specification only illustrated flat surfaces with protruding ribs for use in the finger grip area.

Playtex assigns legal error to the district court's construction of "substantially flattened surfaces" in claim 1. First, Playtex argues it is improper to use expert testimony that contradicts the intrinsic evidence to construe a claim term. Second, it argues that the term "substantial," a term of degree, should not be interpreted as having a strict numerical limitation. We agree.

The district court mistakenly assumed that a surface having less curvature than another surface is necessarily curved, and cannot be flat. This is a false premise in the context of this claim. When we "flatten" a curved surface, we can either make it completely flat, or merely make it flatter than it was originally. Either way, the newly flattened surface would be less curved than the original. Thus, the district court found ambiguity where there is none. "Substantially flattened surfaces" has unambiguous meaning that is resolved solely on the intrinsic record. There was no need for the district court to resort to Dr. Moller's testimony to interpret the disputed term.

The plain language of claim 1, i.e., "substantially flattened," requires neither a perfectly flat surface, nor one that is flat within a manufacturing tolerance. The construction adopted by the district court is erroneous because the '178 patent, on its face, does not describe the tampon applicator at the level of a manufacturing specification. The term "substantially flattened surfaces" is therefore not ambiguous, and its meaning is within the parameters of the written description.

"The term 'substantial' is a meaningful modifier implying 'approximate', rather than 'perfect.'" Liquid Dynamics, 355 F.3d at 1368. But the definition of "substantially flattened surfaces" adopted by the district court introduces a numerical tolerance to the flatness of the gripping area surfaces of the claimed applicator. That reading contradicts the recent precedent of this court, interpreting such terms of degree. In Cordis Corp. v. Medtronic AVE, Inc., 339 F.3d 1352, 1361 (Fed. Cir. 2003), we refused to impose a precise numeric constraint on the term "substantially uniform thickness," noting that the proper interpretation of this term was "of largely or approximately uniform thickness" unless something in the prosecution history imposed the "clear and unmistakable disclaimer" needed for narrowing beyond this plain-language interpretation. Id. Moreover, in Anchor Wall Sys. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298 (Fed. Cir. 2003), we held that "the phrase 'generally parallel' envisions some amount of deviation from exactly parallel," and that "words of approximation, such as 'generally' and 'substantially,' are descriptive terms 'commonly used in patent claims 'to avoid a strict numerical boundary to the specified parameter.'" Id. at 1311. In support of this holding, we noted that "nothing in the prosecution history [of the Anchor Wall patent]. . . clearly limited the scope of 'generally parallel' such that the adverb 'generally' does not broaden the meaning of parallel." Id. Similarly, in this case we find that in claiming "substantially flattened surfaces," Playtex claimed more than flat surfaces.

The drawings do not compel a contrary result. By its reliance on the figures, the district court improperly limited claim 1 to a preferred embodiment. We have consistently advised against this approach to claim construction. See Liquid Dynamics, 355 F.3d at 1369; see also Amgen, Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1325 (Fed. Cir. 2003) ("Because the claims are best understood in light of the specification of which they are a part. . . courts must take extreme care when ascertaining the proper scope of the claims, lest they simultaneously import into the claims limitations that were unintended by the patentee."); Comark, 156 F.3d at 1186-1187 (Fed. Cir. 1998) (advising that in navigating the fine line between reading claims in light of the specification and importing claim limitations, it is appropriate to look to the written description when doing so aids in the interpretation of claim language as opposed to merely detailing the workings of a single embodiment); CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002) (explaining that the
presumption of ordinary meaning cannot be rebutted "simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history"). Claims of a patent may only be limited to a preferred embodiment by the express declaration of the patentee, Karlin Technology, Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 973 (Fed. Cir. 1999), and there is no such declaration here. Claim 1, properly construed, is not limited to the flat surfaces depicted in the drawings.

The prosecution history likewise does not compel a different result. The district court and P&G make much of the fact that, in this case, the patentee distinguished his invention from prior art having "generally cylindrical" finger grips. "Generally," like "substantially," is a term of approximation. See, e.g., Anchor Wall Sys., 340 F.3d at 1311 (Fed. Cir. 2003). The point at which the gripping area curvature ceases to be substantially flattened and becomes generally cylindrical is a question of fact. The need to make a difficult factual determination does not allow the court to surrender material that the patentee clearly and rightfully claimed.

As "substantially flattened surface" has unambiguous meaning in view of the intrinsic record, the district court erred in relying upon extrinsic evidence that directly contradicted that meaning. Vitronics, 90 F.3d at 1583. Dr. Moller's testimony that "substantially flattened surfaces" means "flat within a geometric manufacturing tolerance" effectively defines "substantially flattened" as "flat." With that view, the manufacturing tolerance means any departure from a purely flat surface is bounded within a set range. Dr. Moller further testified that no plastic surface is entirely flat; all surfaces are merely flat within a specified manufacturing tolerance. We think this view reads out the essence of the claim limitation "substantially flattened" as it equates "flattened" with "flat." Such an interpretation contradicts the unambiguous meaning of the term and cannot obtain here. 1

1 Notwithstanding the fact that the district court erred in adopting the construction advocated by Dr. Moller, the district court did not abuse its discretion in admitting the testimony of Dr. Moller into evidence. It is appropriate for courts engaged in claim construction to consider expert testimony. Markman, 52 F.3d at 981 (finding that the trial court did not abuse its discretion when it admitted expert testimony on the issue of claim construction). However, while a trial court may use extrinsic evidence to educate itself about the invention and the relevant technology, it may not use extrinsic evidence to arrive at a claim construction that is at odds with the intrinsic evidence. Elkay Mfg. Co., 192 F.3d at 977.

The disputed claim term is clearly a comparative term. Comparison requires a reference point. Therefore, to flatten something, one must flatten it with respect to either itself or some other object. In the context of the claim, the term "flattened" requires a comparison between the diametrically opposed surfaces and something else. The only antecedent basis in the claim is the tubular barrel. '178 patent, col. 6, ll. 3-9. Playtex, therefore, claimed something flatter than a tubular barrel, but not necessarily something flat.

The issue is whether the patentee properly claimed an oval as a "substantially flattened" circle, or more specifically, an elliptical cylinder as a "substantially flattened" cylinder. In construing the term "substantially flattened surfaces" as something flat in practice the district court erred in going beyond the intrinsic evidence. That evidence clearly indicated that the patent contemplated curved surfaces. Thus, we reverse the district court's claim construction and conclude that "substantially flattened surfaces" means surfaces, including flat surfaces, materially flatter than the cylindrical front portion of the applicator.

3902

d. "substantially flush with adjacent portions"

This disputed language appears in the "whereby" step of claim 1:

whereby said positioning step locates said thin solid formed ornamental panel so as to be substantially flush with adjacent portions of said wheel face outer surface of said wheel such that said decorative layer readily blends with said axial
peripheral lip circumscribing said peripheral rim portion so as to provide a visual impression that said decorative layer is substantially flush with said adjacent portions of said wheel face outer surface and thereby appears to constitute an integral portion of said wheel.

'809 patent, col. 12, lines 1-11. On the issue of indefiniteness, defendants argue that this passage suffers from an internal contradiction. In particular, they contend that the decorative layer cannot both readily blend with the axial peripheral lip and, at the same time, be substantially flush with adjacent portions of the wheel face outer surface. Defendants' contention is premised on "substantially flush with adjacent portions" meaning that the cladding is substantially on the same unbroken level with a horizontally surrounding portion of the wheel face outer surface. Lacks counters by arguing that "substantially flush" as used here means to closely abut and conform to the underlying wheel face outer surface. Both proposed constructions can fit within the plain meaning of the disputed phrase; according to Webster's, "flush" can mean "having or forming a continuous plane or unbroken surface" or "directly abutting on or immediately adjacent to."

--- Footnotes ---

8 This is, in fact, defendants' only construction argument for this claim language.

--- End Footnotes ---

From my preceding interpretations, I have determined that a person of ordinary skill would understand that the wheel face outer surface and the axial peripheral lip are separate but bordering surfaces; that the cladding panel, which covers the entire wheel face outer surface, abuts the axial peripheral lip and thus leaves no exposed wheel face outer surface between it and the lip; and that the decorative layer on top of the panel runs into the axial peripheral lip in such a way as to readily blend. Given these explicit and implicit limitations, I find Lacks' construction of "substantially flush with adjacent portions" to be the meaning an individual of ordinary skill in the art would choose after reading claim 1.

The specification favors this conclusion. In discussing the prior art, it observes that an overlay is needed that "would be capable of closely conforming to the contours of the entire wheel surface." '809 patent, col. 6, lines 3-5 (emphasis added). Accordingly, the specification states that an objective of the '809 patent is "to provide an ornamental overlay for a cast aluminum wheel in which the overlay closely conforms to the contours of the wheel." '809 patent, col. 6, 6-9. Figures 3 and 5 of the preferred embodiments are the clearest statement in the specification of what is actually meant by "substantially flush with adjacent portions." These figures show panels that cover the entire wheel face outer surface and closely abut, or conform to, the styling features of that underlying surface. These figures also show that no wheel face outer surface is left uncovered; the panel and its decorative layer necessarily border the inner shoulder of the axial peripheral lip in order to comply with the "entire wheel face outer surface" and "readily blends" limitations.

I conclude therefore that a person of ordinary skill in the art of cladded wheels, after reading claim 1 and the specification, would understand the phrase "substantially flush with adjacent portions" to mean that the cladding closely abuts or conforms to the underlying contours of the entire wheel face outer surface. Neither party has suggested that the prosecution history might alter this conclusion. Because the intrinsic evidence on "substantially flush with adjacent portions" is adequate for purposes of claim construction, I find it unnecessary to consider extrinsic evidence on the meaning of the phrase (once again, with the exception of Webster's). See id.

3903

Substantially free

Baker Hughes offers the construction "nearly all." ReedHycalog proposes "substantially devoid of catalyzing material, except that many, if not all, the surfaces of the adjacent diamond crystals may still have a coating of catalyzing material." At the hearing, ReedHycalog argued that its construction would "clarify for the jury they are not looking necessarily for something that is essentially clean; but that, in fact, many, if not all—as the phrase says—of the diamond crystals could, in fact, still have a coating on them." Hearing Transcript, 95:23-96:1. The parties then agreed that "substantially free" means "many, if not all." However, replacing "substantially free" in the claim language with "many, if not all" does make sense. Therefore, since the parties agreed during the hearing that the area that is substantially free of the catalyzing material may
still contain some catalyzing material, the Court construes "substantially free" to mean "free of most, but not all, of the catalyzing material."

6. "Density Substantially Greater Than"

a. Construction

This limitation must be construed according to its ordinary meaning. Hallmark contends that because the '496 patent claim requires the compression of three layers of paperboard into a thickness less than the bottom wall, the density must be three times as great in the densified regions. This argument is based on an unstated and unfounded assumption about pleat structure: that the three layers in the unpressed pleat have no gaps or spaces between them. This assumption is probably false in the absence of any evidence that the layers are packed together as closely as possible.

By contrast, James River cites the '500 patent's specification, which states that "since the folded-over areas (pleats) contain substantially more solid fibrous material than the rest of the paperboard; perhaps 40 to 100% more, the density of the folded areas is substantially greater than the remainder of the paperboard." PX-1, col. 12, lines 51-56. Photomicrographs of the pleats show that these regions are substantially free of voids or disruptions. PX-1, col 5, l. 67. Thus, the author has acted as his own lexicographer and provided a definition of this limitation. The density of the pleats must be 40 to 100% greater than the rest of the paperboard.

3905

Side Wall "Extending Substantially Higher" in Element 2

Also in dispute between the litigants is the phrase "extending substantially higher than said front, rear and second side walls to define a protective barrier." M. Mem. 13 states that "substantially higher" plainly means what it says, so its ordinary meaning should apply. But W. Mem. 9 seeks to include the wall's functional purpose--defining a protective barrier--as part of that definition. Under that view, a high wall that did not act as a protective barrier would not conform to element 2.

That position is persuasive, because the functional purpose plainly set forth in the quoted phrase cannot fairly be separated from the structure itself. It would be entirely possible for a side wall to be structurally similar to but functionally different from a wall described in that phrase. Because the claim language expressly states the purpose of the side wall is to act as a protective barrier, a side wall that is "substantially higher" than the other walls but does not serve that function does not come within that element.

19 For example, the added height of a side wall could (1) provide some utility other than acting as a protective barrier or (2) be intended for purely aesthetic purposes.

W. Mem. 11 further argues that such a protective barrier requires "oversize, large or tall articles to directly engage the side wall so that they are prevented from leaning over to engage the side panel of the washing chamber." But nothing in the claim language requires such a further narrowing of the element's terms, and it is not implausible that a side wall can act as a protective barrier without being in direct contact with items in the washer.

In sum, while the term "substantially higher" is construed according to its plain meaning, the higher wall must act as a protective barrier. Whether the side wall of Whirlpool's accused device does in fact act as a protective barrier is a factual question for trial. 20
20 While M. R. Mem. 7-8 wants to debate whether the side wall attachment in Whirlpool's washer acts as a protective barrier, this Court declines to depart from the Markman role of construing the patent's claims by engaging, in essence, in a factual determination of whether the accused device functions in that fashion.

7. "Substantially Homogenous Paperboard Blank"

a. Construction

Hallmark's position is that the limitation means "a paperboard blank that has a uniform composition throughout (i.e. no constituent layers) except for a possible clay coating on one side." It relies on the .499 specification's use of the term "substantially homogenous" in reference to the reformed pleats' fibrous structures. PX-10. Amendment, August 5, 1987, at 6. However, this refers not to the makeup of the paperboard blank, but to the reformation of the pleat layers into a "substantially homogeneous fibrous structure."

James River's position is that the limitation means "a blank that has not had additional layers of paperboard or other non-uniformly dispersed reinforcing material added to its periphery for purpose of increasing the strength of the resulting plate." To support this position, it refers to the '496 specification, which states that 'the blank is a unitary, flat piece of paperboard stock conventionally produced by a wet laid papermaking process...." PX-3. col. 5. lines 56-58. Both the specification and Dr. Page's affidavit indicate the paperboard has a basis weight of 100-400 pounds per ream. PX-003 at 5, lines 60-66; Page Aff. P 11. In addition, the thickness should be about 0.008 inch to 0.050 inch. PX-003 at 5, lines 62-63. More importantly, the specification states what would make the blank non-homogenous. In distinguishing the prior art, the specification discloses that earlier processes strengthened the plate by adding layers of paperboard around the blank's edge. PX-3. at 2, lines 30-31.

Finally, James River contends that the specification makes clear that cosmetic layers may be present in the blank. These are added for reasons other than adding strength. Specifically, the specification provides that liquid proof coating or ink may be added. PX-3. col. 6, lines 13-24. Hallmark contends that the laminated paperboard's additional layers are not entirely cosmetic, but that they add strength.

The specification reveals that the meaning of the claim limitation: in addition to having the basis weight and thickness outlined in the specification, the blank must have not had additional layers of paperboard or other non-uniformly dispersed reinforcing material added to its periphery for the purpose of increasing the plate's strength. This allows for less than perfect homogeneity or uniformity in the paperboard blank. It also makes clear that the invention's achievement of adding strength is due to the process used, not to the materials in the blank. In addition, it allows the patent-holder protection of its invention against those who would make minor, cosmetic changes to the paperboard yet gain the benefit of using the invention.

In this case, the claim limitations at issue in Claim 10 consist of an exercise and play apparatus comprising:

(1) "an inflatable, substantially horizontally oriented bottom wall having an upper surface, a lower surface and a perimeter";

(2) the upper and lower surfaces [of the bottom wall] being spaced apart throughout the bottom wall by a distance sufficient to generate a trampoline effect based on air pressure between the upper and lower surfaces";
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

(3) "an inflatable, substantially vertically oriented sidewall extending upwardly from and continuously along the upper surface of the bottom wall";

(4) "said sidewall defining a continuous perimeter of an enclosed, upwardly open central play area on said bottom wall around said play area"; and

(5) "[said sidewall] extending upwardly from said bottom wall to provide a cushioned perimeter wall around said play area, the sidewall having a height and thickness selected to retain, as well as cushion the impact of users jumping on the upper surface of the bottom wall."

[Second] Decl. of David N. Makous, Exh. E at 63-64.

The Court has already determined that the term "substantially horizontally oriented" is something that "lies relatively flat." September 19, 1997 Order at 18. The Court has also determined that the phrase "upwardly open central play area" is properly interpreted to define the area where "one or more users can . . . enter the play area and jump, bounce, or crawl on the bottom wall." September 19, 1997 Order at 18. The Court has further noted that the perimeter of the play area in the '738 patent is explicitly defined by the sidewall, which "extend[s] upwardly from the outermost bottom wall compartment or section 20." September 19, 1997 Order at 19. Finally, the Court has held that the bottom wall and the sidewall of the '738 patent cooperate to define the play area. September 19, 1997 Order at 19.

3908

16. Substantially identical size distribution

FieldTurf's Proposed Construction: "The sizes of the particles of hard and resilient granules in the intermixed bottom course having a range spanning a numerical difference of 40 screen mesh standard"

SCG's Proposed Construction: "An arrangement of particles such that the graphic line for hard particles and the graphic line for resilient particles are superimposed on each other on a conventional soil laboratory sieve analysis"

SCG's Proposed Construction of "Size distribution": "Frequency of occurrence of particles having a given physical magnitude"

The Court's Claim Construction: "80% by weight of hard and resilient granules in the bottom course distributed in a range spanning a numerical difference of no more than 40 screen mesh standard."

The only appearance of "substantially identical size distribution" in the claims of the patents-in-suit is in the'752 patent. Claim 1 of the '752 patent includes the following claim language related to the bottom course: "a bottom course of intermixed hard and resilient granules of substantially identical size distribution, disposed upon the top surface of the backing . . . ." FieldTurf first claims that "substantially identical size distribution" should be submitted to the jury without further explanation because it can be understood according to its ordinary meaning. As an alternative, it states that it would find "the sizes of the particles of hard and resilient granules in the intermixed bottom course having a range spanning a numerical difference of 40 screen mesh standard" to be acceptable.

SCG responds by seeking separate definitions for "size distribution" and "substantially identical size distribution." It points to a portion of the specification that generally discusses the "size distribution" as supporting its definition of "frequency of occurrence of particles having a given physical magnitude." '752 patent, 6:9-19. SCG also defines the full phrase "substantially identical size distribution" as "[a]n arrangement of particles such that the graphic line for hard particles and the graphic line for resilient particles are superimposed on each other on a conventional soil laboratory sieve analysis." '752 patent, 6:13-23.

As a first point, the Court finds it appropriate to define "substantially identical size distribution" and to do so for the whole claim term. As the Court noted earlier, a patentee may be his own lexicographer. Here the specification states the following:
By "substantially identical" size distribution it is meant that when the bottom infill layer is analysed through conventional soil laboratory sieve analysis, and graphically presented on a standard sieve analysis semi-logarithmic graph (y-axis showing 0-100 percent passing the sieve size or smaller by weight and x-axis showing sieve/particle size logarithmically) the line for hard particles and the line for resilient particles are ideally superimposed on each other to a substantial extent. Therefore the hard and resilient particles have substantially equal particle sizes and the distribution of sizes is substantially the same.

'752 patent, 6:13-23. Shortly thereafter, the '752 specification states that:

Applying this practice to the invention, numerically or scientifically defined, where the particle sizes of 80% by weight of hard and resilient granules in the bottom course are distributed in a range spanning a numerical difference of 40 screen mesh standard, the particle size distribution is considered substantially identical or very well sorted.

'752 patent, 6:34-39.

Considering the specification as a whole, the Court finds that the proper construction of "substantially identical size distribution" is "80% by weight of hard and resilient granules in the bottom course distributed in a range spanning a numerical difference of no more than 40 screen mesh standard." The Court prefers this over a construction based on comparison of the "graphic lines" of the particles because it provides certainty. It is difficult to objectively ascertain whether lines are "ideally superimposed" and thus, as the specification acknowledges, such a measurement is "by nature an imprecise 'rough and ready' measure . . . ." '752 patent, 6:24-25. This is the reason why the 80% by weight, 40 screen mesh standard is proposed in the specification. '752 patent, 6:24-33. Finally, the Court's definition clarifies that the 40 screen mesh standard is a maximum, as is clear from the specification language that lower screen mesh distributions such as 20 are preferred. '752 patent, 6:40-52.

2. Construction of Additional Term

Defendant notes that the term "substantially identically shaped" was not addressed in the court's March 30, 2006, Order, and requests the court construe the term. (Def.'s Mot. for Summ. J. of Noninfringement 11.) Defendant argues that this term should mean that the teeth are "approximately identical in characteristics such as size and shape." (Id. 12.)

Most of the time, as here, the words or terms which the parties ask the court to construe are the best words or terms that could have been chosen. However, to say that "substantially" means "substantially" undoubtedly would not pass appellant scrutiny. The use of the term "substantially" suggests that the objects in question are "approximately" or "almost" identically shaped. See Anchor Wall Sys. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1311-12 (Fed. Cir. 2003) (noting that "words of approximation, such as 'generally' and 'substantially,' are descriptive terms commonly used in patent claims to avoid a strict numerical boundary to the specified parameter" (internal quotations omitted; citations omitted)).

Defendant argues that the ordinary meaning of the word "identical" means "being exactly equal and alike." (Def.'s Mot. for Summ. J. of Noninfringement 11-12.) Construing this with the ordinary meaning of shape, defendant argues that the phrase requires uniformity of size and shape. (Id. 12.) That construction would substantially (i.e. just about or almost) read the word "substantially" out of the description. Even accepting defendant's definition of shape--having or fashioned to a particular form--the court cannot accept defendant's construction of this phrase. The definition of shape makes no reference to size. Instead the court will construe "substantially identically shaped" to mean "having a particular form that is approximately exactly alike." A high degree of similarity in shape, but not mathematical exactness, is required. Liquid Dynamics Corp. v. Vaughan Co., 355 F.3d 1361, 1368 (Fed. Cir. 2004) ("The term 'substantial' is a meaningful modifier implying 'approximate,' rather than 'perfect.").
Claim Construction

For purposes of this motion for summary judgment, Vector has conceded that its scale has all of the elements of the patent claims with the exception of the element of the sliding weight "when in its zero position having a portion thereof disposed substantially in an imaginary plane containing the fulcrum of the beam." For convenience, the court will refer to this element as the "zero position" element.

The principal objective of this patent is "to provide a lightweight, miniaturized, portable scale which can easily and comfortably be transported in a person's shirt or coat pocket." 428 Patent at 2:32-35. Thus, the goals are to reduce the size and weight of the scale and to be able to manufacture the scale easily and inexpensively. The scale is composed of a carrying case and a weighing mechanism that comprises a balance beam mounted for pivotal movement on a fulcrum provided by a pair of fulcrum posts. In order to weigh amounts up to the desired capacity, the scale must either have a long balance beam or use a heavy coarse sliding weight, which would increase both the size and the weight of the scale. Id. at 1:57-61. In the patent, the length of the balance mechanism of the scale is kept to a minimum by using a sliding weight that has a metallic insert to add to its mass, which allows the scale portion to be shortened but still have the higher weighing capacity. Id. at 1:43-48. The specification explains that in order to hold down the mass of the scale, the sliding weight is constructed in such a manner that the metallic insert therein rests essentially in the plane of the fulcrum for the balance beam when the sliding weight is in its zero position. In this position the metallic insert is essentially neutral so far as the balance of the mechanism is concerned." Id. at 1:51-56. In the best mode section, the specification further explains, referring to the drawings,

the coarse weight 35 is constructed in such a manner that the heavy metallic insert therein is offset from the pointer 37 of the weight in the direction of the fulcrum 19 for the balance beam 18. Indeed, the metallic insert 44 is offset to an extent that when the coarse sliding weight 35 is in its zero position, adjacent the cross-bar portion 27 of balance beam 18, the metallic insert is disposed substantially in the plane of fulcrum 19, i.e., the imaginary vertical plane containing the center lines of fulcrum posts 21 and 22. With the center of insert 44 alligned [sic] precisely in the plane of fulcrum 19 the insert becomes essentially neutral so far as balance of the balance beam 18 and the holder 28 are concerned when the weight 35 is in its zero position and the holder 28 is empty.

Id. at 5:12-27. When the coarse weight is moved away from the zero position and "moved away from the plane of [the] fulcrum" the full mass of the metallic insert can be used to offset and measure the weight of substances. Id. at 5:31. Thus, Claims 1 and 4 specifically define this feature of the invention: "said sliding weight when in its zero position having a portion thereof disposed in an imaginary plane containing the fulcrum of the beam, whereby to minimize the weight of the substance holder required to balance the beam when the sliding weight is in its zero position." Id. at 6:25-30, 57-62.

Vector argues that its scale does not literally infringe Claims 1, 2, 4, and 5 of the 428 Patent because it does not have a sliding weight that, when in the zero position, is in the imaginary plane of the fulcrum. Vector argues that the court should construe the claim limitation "substantially in the plane of the fulcrum" to mean that a substantial portion of the weight has penetrated and rests in the imaginary plane. Vector argues that no portion whatsoever of the sliding weight in its scale extends into the plane of the fulcrum or even any plane containing any part of the fulcrum post, and, in fact, it is physically impossible for the sliding weight of the vector scale to enter the imaginary plane of the fulcrum.

Deering, of course, argues for a broader construction of this element. Deering argues that Vector's claim interpretation reads out the term "substantially" from the claim language. Deering proposes that the court construe the claim language, "disposed substantially in the plane of the fulcrum," as meaning that the weight is either at or "close to" the plane of the fulcrum so as to minimize the weight of the beam. (Deering's Mem., at 6.) Under Deering's proposed construction, the weight need not enter the imaginary plane but need only be close to the plane. Thus, Deering argues that the weight in Vector's scale, which its expert asserts is only 1/10 inch away from the fulcrum, is "substantially in the plane of the fulcrum."

After reviewing the intrinsic evidence, the court finds that Vector's claim construction is correct and supported by the claim language and the specification. The claims require that the weight be "disposed substantially in an imaginary plane
containing the fulcrum." (Emphasis added.) The patent covers a scale where the weight is "substantially in" the plane, not a weight that is outside but close to the plane. In common usage, "substantially" means significantly or considerably. In the claims at issue, the word "substantially" describes how the weight is "disposed" in the "imaginary plane." The specification sheds further light on the proper construction when, in reference to the relationship between the weight and the imaginary plane, it states that the metallic insert "rests essentially in the plane of the fulcrum for the balance beam." Id. at 1:51-56. When describing the best mode for carrying out the invention, the specification states that "with the center of insert 44 aligned [sic] precisely in the plane of fulcrum the insert becomes essentially neutral." Id. at 5:22-24. While this describes the best mode for carrying out the invention, it indicates that the intent is to have the weight "in" the "imaginary plane," and in the best mode it would be "precisely in the plane." Thus, the court construes the element requiring the sliding weight to be "disposed substantially in an imaginary plane containing the fulcrum" to mean that the weight must enter and penetrate the imaginary plane containing the fulcrum of the beam.

In the present appeal, Deering contests the district court's construction of the Zero Position Limitation: "said sliding weight when in its zero position having a portion thereof disposed substantially in an imaginary plane containing the fulcrum of the beam." The Zero Position Limitation is present in every claim at issue in this action. In particular, Deering objects to the construction of the terms "substantially in an imaginary plane." It specifically contends that the term "substantially" means "at or near."

This court is asked, once again, to construe the meaning of the term "substantially" in a patent claim. See, e.g., Epcon Gas Sys., Inc. v. Bauer Compressors, Inc., 279 F.3d 1022 (Fed. Cir. 2002) (construing the terms "substantially constant" and "substantially below"); Zodiac Pool Care, Inc. v. Hoffinger Indus., Inc., 206 F.3d 1408 (Fed. Cir. 2000) (construing the term "substantially inward"); York Prods., Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568 (Fed. Cir. 1996) (construing the term "substantially the entire height thereof"); Tex. Instruments Inc. v. Cypress Semiconductor Corp., 90 F.3d 1558 (Fed. Cir. 1996) (construing the term "substantially in the common plane"). In conducting this analysis, we begin with the ordinary meaning of the claim terms to one of ordinary skill in the art. Prima Tek, 318 F.3d at 1148. Reference to dictionaries and our cases indicates that the term "substantially" has numerous ordinary meanings. As the district court stated, "substantially" can mean "significantly" or "considerably." The term "substantially" can also mean "largely" or "essentially." Webster's New 20th Century Dictionary 1817 (1983). Indeed, our cases recognize the dual ordinary meaning of this term as connoting a term of approximation or a term of magnitude. See Epcon, 279 F.3d at 1031 ("The phrase 'substantially constant' denotes language of approximation, while the phrase 'substantially below' signifies language of magnitude, i.e., not insubstantial.").

Since the term "substantially" is capable of multiple interpretations, we turn to the intrinsic evidence to determine which interpretation should be adopted. Ecolab, 264 F.3d at 1366; Gart, 254 F.3d at 1339-40.

As is often the case, the written description does not explicitly identify the meaning of the term "substantially." The specification does, however, provide the public with a significant explanation of the criticality of the location of the sliding weight in conjunction with the plane created by the fulcrum so as to support a finding that the term "substantially" is a term of magnitude as opposed to approximation. First, the stated object of the '428 patent is to provide a lightweight, portable scale. The written description plainly states:

To hold down on the mass of the substance holder portion of the mechanism required to achieve equilibrium of the mechanism the sliding weight is constructed in such a manner that the metallic insert therein rests essentially in the plane of the fulcrum for the balance beam when the sliding weight is in its zero position.

1428 patent, col. 1, ll. 48-54 (emphasis added). Figure 5, supra, shows an example of the position of the sliding weight that meets the limitation. In Figure 5, the metal insert of the sliding weight is precisely in the plane, as the written description states:

With the center of insert 44 aligned precisely in the plane of fulcrum 19 the insert becomes essentially neutral so far as balance of the balance beam 18 and the holder 28 are concerned when the weight 35 is in its zero position and the holder 28 is empty. This greatly minimizes the amount of mass that must be incorporated into the holder 28 portion of the weighing
mechanism 17.

Id. at col. 5, ll. 12-29 (emphasis added). The placement of a portion of the weight in the plane of the fulcrum is the stated structural orientation that provides the benefits of minimization of weight and portability. The preferred embodiment places the center of the insert--clearly the major contributor to the total mass of the weight--precisely in the plane. We, however, do not generally limit claims to the preferred embodiment. Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998). This is particularly significant because the claim language does not contain the explicit requirement that the metal insert of the weight be "essentially in the plane" containing the fulcrum.

It is proper, however, to construe the term "substantially in the plane" in light of the specification. Apex Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1373 (Fed. Cir. 2003) ("Claims are interpreted in light of the specification and with the knowledge of one of ordinary skill in the art."); Vitronics, 90 F.3d at 1582. The written description, as a whole, clearly requires that a portion of the metal insert of the weight penetrate the imaginary plane containing the fulcrum of the beam to minimize the weight of the scale and facilitate portability. There is no disclosure suggesting that a portion of the weight need only be located at or near the plane as Deering suggests. For this reason, we agree in part with the district court's construction of the Zero Position Limitation as requiring at least a portion of the weight to intersect the plane containing the fulcrum. We agree with the district court's claim construction only in part because the district court's construction effectively reads the term "substantially" out of the claims by construing the claim to read on any slight penetration of the plane. This error, however, is harmless because, as discussed above, the term "substantially" is a term of magnitude requiring a "not insubstantial" portion of the weight to intersect the plane containing the fulcrum. Wepon, 279 F.3d at 1031. Because this construction is actually narrower than the district court's construction, it does not affect the district court's ultimate finding of noninfringement with respect to the VX-10. Accordingly, in light of the ordinary meaning of the term "substantially" and in view of the written description, we construe the Zero Position Limitation as requiring a not insubstantial portion of the weight to intersect the plane containing the fulcrum.

On appeal, Deering argues that the term "substantially in" means "at or near the imaginary plane." Deering argues that any other interpretation reads the term "substantially," one of approximation, out of the claim. As discussed above, the term "substantially" in this context is used as a term of magnitude, describing the extent of the portion of the weight in the plane defined by the fulcrum, not as a term of approximation.

9. What is the Proper Construction for the Phrase "substantially incapable of fibrillation under normal conditions" in the '722 Patent?

Claim 1 of the '722 patent contains the phrase "said binder particles being substantially incapable of fibrillation under normal conditions into microfibers of less than 10 micrometers diameter at room temperature. . . ." KXI contends this phrase means that prior to any type of processing, the binder particles are substantially incapable of forming fibers of less than 10 micrometers diameter by shear and pulling alone without heating or substantial compression. Culligan contends this phrase means that the binder particles are substantially incapable of forming fibers of less than 10 micrometers when mechanically worked at room temperature. According to KXI, "the only real area of dispute between the parties is the requirement that the test for fibrillation occur prior to any processing of the binder, i.e., prior to any heating or substantial compression."

KXI argues that the '722 patent's specification only mentions fibrillation of binder particles when it discusses prior art processes utilizing a polytetrafluoroethylene ("PTFE") binder. This is at column 3, lines 53-55, which reads: "PTFE is unique in that it fibrillates without heating or applying substantial compression but by shear and mixing." KXI contends this sentence from the specification defines the phrase "normal condition" to mean applying shear and pulling alone without heating or substantial compression prior to processing.

In support of its "mechanically worked" definition, Culligan cites column 3, lines 58-61 of the '722 patent specification. This section reads: "the foregoing process using PTFE is complex and time consuming and involves the evolution of fine fibers by mechanically working and shearing a mixture of PTFE and particles."
According to Culligan, the '722 patent's specification is silent as to the meaning of the phrase "substantially incapable of fibrillation." Culligan asserts that the prosecution history of the Australian counterpart to the '722 patent states that this language "was employed to exclude PTFE." The patentee apparently argued in prosecuting the Australian patent, "this is because the PTFE fibrillates by shear and pulling alone at room temperature, i.e., without the necessity for heating or applying substantial compression."

Culligan argues KXI's definition is incorrect because KXI appears to contend that no compression at all may be applied during the test to determine fibrillation, as opposed to no "substantial compression." Also, Culligan objects to the phrase "prior to processing" if it means something other than "prior to processing the binder in accordance with the method disclosed in the '722 patents. . . ."

KXI argues the court need not decide which party is correct because, as a matter of law, this claim limitation must include the crystalline thermoplastic polymers, including polyolefin, listed in claim 33 of the '722 patent. Claim 33 depends from claim 1. It reads: "the composition of claim 1 wherein the binder material forming the matrix is a crystalline thermoplastic polymer selected from the group consisting of . . . polyolefins. . . ." KXI argues that, as a matter of law, the independent claim must be interpreted broadly enough to include the dependent claim, citing Wright Medical Tech., Inc. v. Osteonics Corp., 122 F.3d 1440, 1445 (Fed. Cir. 1997) ("We must not interpret an independent claim in a way that is inconsistent with a claim which depends from it."). KXI contends that, as a matter of claim interpretation, polyolefin is "substantially incapable of fibrillation under normal conditions into microfibers of less than 10 micrometers diameter at room temperature" as that phrase is used in claim 1 of the '722 patent.

Culligan argues that KXI has inverted the law of claim interpretation concerning dependent claims. Instead of reading the dependent claim (claim 33) as a further limitation on the independent claim (claim 1), KXI reads the independent claim as a limitation on the dependent claim. Instead, KXI argues dependent claim 33 must meet the conditions of independent claim 1.

Without further evidence, the court declines to construe claim 33 to mean that polyolefin is "substantially incapable of fibrillation under normal conditions into microfibers of less than 10 micrometers diameter at room temperature" as that phrase is used in claim 1 of the '722 patent. The court declines to add a "prior to processing" requirement to claim 1, as the court finds this is not supported by the evidence. Otherwise, the court agrees with KXI that the phrase "said binder particles being substantially incapable of fibrillation under normal conditions into microfibers of less than 10 micrometers diameter at room temperature. . . ." means that the binder particles are substantially incapable of forming fibers of less than 10 micrometers diameter by shear and pulling alone without heating or substantial compression.
intersecting lines. According to Euclid, even a 90 degree corner is an incline. However, the "[Euclid] concept is . . . broader than our modern concept of angle." Supp. Shen Dec. Ex. O. Most importantly, the patentee did not define "substantially inclined" anywhere in the specification or in the patent claims themselves. So, while the patentee can act as his own lexicographer, Mardikian did not do so. For that reason, the Court adopts the ordinary meaning of the term "substantially inclined" rather than the ancient understanding from Euclid.

Next, the Court interprets the prosecution history, as it may serve to limit a claim and exclude any interpretation of language in a claim that was surrendered during prosecution. See Spectrum Int'l, 164 F.3d at 1378 (finding that "explicit statements made by a patent applicant during prosecution to distinguish a claimed invention over prior art may serve to narrow the scope of a claim"). In fact, the prosecution history confirms that Plaintiff intended the meaning of "substantially inclined" to exclude vertical shock absorbers. During the patent prosecution, after his claims had been rejected, Mardikian told the Patent Examiner that his "substantially inclined" shock absorbers are "markedly different" than the shock absorbers in the prior art, all of which were in vertical or substantially vertical positions. Specifically, Plaintiff stated that: "the present wording of the claims [substantially inclined] structurally distinguishes from the cited references [Frank, Hill and Wann] . . . All of these features are markedly different from the spring mounted seats of the prior art record." Antonsson Dec; Shen Dec Ex H, 6/17/93 Amend. at 7-8 (emphasis added). Plaintiff distinguished himself from the prior art, which had vertical shock absorbers, and cannot now include geometric positions that he surrendered. Thus, the Court interprets the meaning of "substantially inclined" in independent claims one, six and nine as the dictionary defines it and such that vertical or substantially vertical angles are not "substantially inclined."

The next issue of claim construction for the Court is where the shock absorbing means is substantially inclined from; in other words, what is the point of reference from which to measure the angle with a protractor. Defendant Bombardier argues that the point of reference is the hull line of the jet ski. According to Claude Gagnon, the Project Manager of Advanced Concept for the Ski-Doo Division, the hull line is the customary reference frame for geometric positioning of various components in the field of personal watercraft or boat design. See Supp. Shen Dec Ex M, Gagnon Dep. Indeed, Plaintiff's former counsel, in pre-suit correspondence, stated that "the term 'substantially inclined longitudinal axis' is that the shock absorber is substantially inclined relative to the longitudinal axis of the hull or the hull line." Supp. Shen Dec, Ex N.

Plaintiff argues that the point of reference is either the horizon or a plane through the seat of the jet ski. Under the horizon as the reference point theory, the shock absorber, which Plaintiff admits would be vertical to the horizon when the jet ski is motionless, becomes inclined when the jet ski pitches forward and backward while in use. The Court rejects this argument, as analysis of what is infringing cannot fluctuate depending on whether the allegedly infringing product is in use or not. Under this theory, and under the Court's construction of "substantially inclined," infringement would be a random occurrence. The horizon as a reference point theory is rejected by this Court because it conflicts with the general purpose of patents, which is to set out the specific metes and bounds of an invention so that other inventors can avoid infringement. See Athletic Alternatives, Inc. v. Prince Mfg. Inc., 73 F.3d 1573, 1581 (Fed. Cir. 1996). Plaintiff's other suggested reference point, an arbitrary plane through the seat of the jet ski, is also rejected by the Court. Plaintiff argues that a plane through the seat of Defendant's HX and XP watercraft forms an 80 to 90 degree angle with the shock absorber. Although even under Plaintiff's plane through the seat theory Defendant's products are still not "substantially inclined," as this Court interprets the terms to exclude vertical or nearly vertical angles such as 80 to 90 degrees, the Court still rejects both of Plaintiff's theories regarding the reference point. The Court agrees with Defendant and adopts the hull line as the reference point because the evidence shows that this is the customary reference point. 1

1 The Court does not address Plaintiff's arguments regarding the alleged requirement that the shock absorber must be substantially aligned with the direction of movement of the seat because this alleged requirement is not part of the claims and therefore not relevant to claim construction. See Comark, 156 F.3d at 1186-87 (finding that limitations that appear only in the specifications and not in the claims themselves, may not be read as limitations of the claim).
2. "Substantially Integrated Fibrous Structures Generally Inseparable Into Their Constituent Layers"

a. Construction

The parties strongly dispute this key claim limitation. Though the wording among the four patents varies as to this limitation, the parties agree that they should be similarly construed.

James River's position is that this limitation must focus on the elimination of voids or disruptions between the layers of the pleat after compression. According to this view, the substantially integrated fibrous structures are compressed pleats in which tightly compacted fibers are compressed and bonded together substantially without voids or disruptions therein. PX-9, Amendment and Response, 12/16/83, at 4. Moreover, James River argues that Hallmark's error is in importing the description of the preferred embodiment of the invention into the construction of the claim. This would require the elimination of virtually all voids and disruptions so as to obliterate the distinctions between the layers.

Hallmark's position is that this limitation means that "almost all, if not all, of the fibers of the three thicknesses of paperboard that form the pleat, have been broken down and reformed from their original structure to a homogeneous new structure such as those shown in Figures 9 and 10 of the patent." In addition, "any voids or disruptions in the rim area are compressed out and new bonds are formed between the tightly compacted fibers." Furthermore, "once the required three layers of paperboard are reformed, they are inseparable back into the three layers of paperboard" so that the "identity of the three layers of paperboard used to make the pleats must have been eliminated or obliterated." Hallmark bases its position on the changes the applicants made in their claim during the course of the prosecution while narrowing the claims to overcome the PTO's prior art rejections.

In view of the claim language and the prosecution history, the meaning of the claim limitation is clear. As observable in specifications' photomicrographs, the layers must be compressed so as to substantially eliminate the voids and gaps that are present in prior art plates. The specification and the prosecution history teach the proper comparisons to use in determining whether the voids and disruptions have been adequately reduced. The two proper comparisons are between the prior art plates' pleats and those in the invention's plates, and between the center and the pleats of the invention plates. 1 '140 patent at 11-12, lines 31-43; PX-9 at 62-63, Amendment and Response of December 16, 1983 at 3. A small portion of the densified regions may not be entirely reformed in this way, but the substantial portion of the pleat has been reformed. PX-6 at 71.

--- Footnotes ---

1 It is also true that the specification and the prosecution history teach that the density of the compressed pleats is higher than that of the bottom of the plates as shown in Fig. 8 of the '140 patent. However, density is not a part of this claim limitation. Moreover, while the existence of gaps and voids would affect a region's density, it might be counteracted by the existence of areas of extremely compacted fibers. Thus, density is considered only as a part of claim limitation 6, below.

--- End Footnotes ---

However, the layers cannot be simply compressed; they must be reformed, as shown by the loss of individual identity. This loss of the layers' individual identity occurs because the former layers are bonded together at the fiber level. Thus, the loss of layer identity is manifested by the pleats being "generally inseparable into their constituent layers." This key aspect was added just before the allowance of claims in both the '140 and '496 patents. PX-7, Preliminary Amendment at 1; PX-6, Amendment at 10-11. The prior art's pleat structures constituted "areas of weakness because of the ease with which they could separate into their constituent layers permitting the container to flatten to its previous planar state." PX-6, Amendment at 10. Moreover, the phrase "in which the constituent layers generally lack individual identity" was added to the '499 and '500 claims just before their allowance. PX-10 at 72-74; PX-11 at 65-66. This is consistent with the applicant's remark in the prosecution history of the '496 patent that the "fibrous structures of the densified regions no longer retain the individual identity of the layers which constitute the structures." Thus, if force is applied to the pleats, the pleats should not unfold. If they unfold, the pleats would by definition be composed of layers that retain an aspect of their individual identity.

The plain language of the claim is not inconsistent with the definition suggested by the prosecution history. Loss of individual identity at the level of individual layers and fibers is manifested as a tendency not to separate into constituent layers. For this reason, methods other than photomicrographs may be useful in determining whether the densified regions
are generally inseparable into constituent layers.

As to the meaning of "substantially integrated." Hallmark contends that "the term 'substantially' is an imprecise word of degree that renders the claim invalid under 35 U.S.C. § 112 (indefinite) unless the specification provides some standard for specifically defining that term." Seattle Box Co. v. Indus. Crating & Packing, Inc., 731 F.2d 818, 826 (Fed. Cir. 1984). An imprecise claim limitation does not impart invalidity to the claims but rather must be considered in determining infringement. Andrew Corp. v. Gabriel Electronics, Inc., 847 F.2d 819, 822 (Fed. Cir. 1988) (citing W.L. Gore & Associates, Inc. v. Garlock, Inc., 842 F.2d 1275, 1280 (Fed. Cir.), cert. denied. 488 U.S. 927, 109 S. Ct. 312, 102 L. Ed. 2d 330 (1988)). The test is that "if the claims, read in the light of the specification, reasonably apprise those skilled in the art both of the utilization and scope of the invention, and if the language is as precise as the subject matter permits, the courts can demand no more." Shatterproof Glass Corp. v. Libbey-Owens Ford Co., 758 F.2d 613, 624 (Fed. Cir.) (cites omitted), cert. dismissed, 474 U.S. 976, 106 S. Ct. 340, 88 L. Ed. 2d 326 (1985).

The fact that the specification teaches the comparison of prior art and invention photomicrographs of the rim pleats gives sufficient definition to the term "substantially." One skilled in the art could recognize the difference between prior art pleats and the invention plate's pleats. It is permissible for there to be a range between the prior art and the preferred embodiment that is still included in the claim. In this context, "substantially" allows for something short of absolute elimination of gaps and voids. It does require that comparison of photomicrographs reveal to one skilled in the art that the gaps and voids are distinctly reduced as compared to the prior art.

The district court's entry of judgment of non-infringement of the '068 patent. Therefore, this appeal is limited to the issues relating to the '382 patent. The '382 patent discloses a vacuum system for cleaning swimming pools. The pool cleaner system comprises four elements, as set forth in Claim 1 of the patent:

(a) a forwardly inclined body having a flow passage therethrough;
(b) an inlet foot having a water inlet, the inlet foot being attached to the body and connected to the flow passage and when in use, is proximate to a surface to be cleaned;
(c) a flexible disc surrounding the water inlet and rotably connected to the inlet foot, and having a peripheral edge; and
(d) a stop for preventing upward flexing of the peripheral edge beyond a predetermined amount located forward of the body and above and substantially inward of the peripheral edge.

A drawing of the system as claimed by the '382 patent is provided in the single figure of the patent, and is set forth below:

--- Footnotes ---
1 Although Zodiac's Enumeration of Errors includes the district court's rulings on the '068 patent, Zodiac represents in its Reply Brief that it no longer challenges these rulings in this appeal.

--- End Footnotes ---

As described in the '382 patent, pool cleaners of the type claimed move in a step-wise manner automatically and in random fashion over submerged surfaces to be cleaned. As the cleaner moves, it traverses from horizontal surfaces to vertical surfaces, as well as the reverse. Unfortunately, the cleaner often becomes unbalanced as it moves around the pool, leaving the cleaner oriented away from the surface and the cleaner inlet away from the target surface. This reduces the cleaner's effectiveness, unless one attaches a cumbersome weight to one side of the cleaner and a float to the other side. While the
weight and float solve the problem of orientation, they render the cleaner more burdensome to use. In addition, the disc of the typical cleaner resists and hinders the movement of the cleaner from horizontal to vertical surfaces and can cause damage to pools with vinyl sheet liners.

The invention of the '382 patent offers an alternative for keeping the cleaner properly oriented and the inlet close to the target surface. Instead of a weight and float, the invention uses an attached stop (13) for preventing the disc (6) from flexing upward as it moves across the surface. The stop is located upward and above the disc, and is attached to the body of the cleaner. Because the disc remains flat, the cleaner maintains a proper orientation. Properly oriented, the inlet remains close to the surface.

The district court granted Hoffinger's motion for summary judgment that it did not literally infringe either of the asserted patents. See Baracuda Int'l Corp. v. Hoffinger Indus., Inc., 4 F. Supp. 2d 1188, 1198 (N.D. Ga. 1998). The court also held as a matter of law that Hoffinger did not infringe the '068 patent under the DOE. Concomitantly, the district court granted Zodiac summary judgment on the issue of the validity of the '382 patent, and held that genuine issues of material fact precluded summary judgment on the issue of infringement of the '382 patent under the DOE. See id. The district court further held that fact issues precluded summary judgment on the issue of willfulness. See id.

Thereafter, the district court held a five-day jury trial on all outstanding issues. At issue were four claims of the '382 patent: independent claim 1 and dependent claims 2, 3 and 10. During the trial, Zodiac presented evidence that Hoffinger's accused devices included each of the four limitations of claim 1. In particular, the jury heard testimony from ten witnesses, received 55 exhibits and viewed a demonstration both live and on videotape of the Hoffinger devices in operation. The jury also heard testimony and reviewed other evidence on the specific issue of whether Hoffinger's weight arm was equivalent to the stop set forth in limitation (d).

Hoffinger effectively conceded that its accused devices included the first three limitations of independent claim 1. It vigorously denied, however, that its devices included the fourth limitation, (d): "a stop for preventing upward flexing of the peripheral edge [of the flexible disc] beyond a predetermined amount located forward of the body and above and substantially inward of the peripheral edge." Hoffinger produced evidence that its weight arm could not function as the stop in limitation (d), because its arm extended at least to the peripheral edge of the disk, and thus was not located "substantially inward" thereof. As a result, argued Hoffinger, its devices did not infringe the '382 patent at all. If anything, Hoffinger continued, its devices practiced the prior art disclosed in United States Patent No. 4,023,227 (the "'227 patent"), which is owned by Kreepy Krauly U.S.A., Inc. ("KK") and has since expired. Hoffinger also argued that its devices practiced aspects of other KK patents that it has licensed.

At the close of evidence, both parties moved for JMOL. Both motions were denied, and the court submitted the case to the jury. The jury found that Hoffinger not only infringed the '382 patent under the DOE, but did so willfully. It then awarded Zodiac damages in the amount of $1.976 million.

After the verdict, both parties renewed their motions for JMOL. Citing this court's decision in Sage Products, Inc. v. Devon Industries, Inc., 126 F.3d 1420, 44 U.S.P.Q.2D (BNA) 1103 (Fed. Cir. 1997), Hoffinger argued that the asserted claims included specific structural limitations, and "the doctrine of equivalents cannot be used to expand those claims to cover foreseeable alterations, such as Hoffinger's weight arm, that were not specifically claimed by the patentee." Zodiac responded that Hoffinger had waived its right to renew its JMOL motion on the issue of infringement because it did not expressly renew the motion with specificity during its argument after the close of evidence. Zodiac also asserted that Sage Products did not limit the jury's authority to find infringement under the DOE.

- 4573 -
The district court granted Hoffinger JMOL on the issue of infringement of the '382 patent under the DOE. The district court initially held that under Fed. R. Civ. P. 50, Hoffinger had preserved its right to renew its JMOL motion during its argument to the court after the close of evidence when it specifically addressed the issue of Zodiac's claim for lost profits. The court stated that it "understood the Defendant to be renewing its Rule 50 motion in its entirety, but only rearguing the point relating to the issue of lost profits." Moving to the merits of Hoffinger's motion, the district court noted our holding in Sage Products that "because [an] issued patent contains clear structural limitations, the public has a right to rely on those limits in conducting its business activities." Id. at 1424. 44 U.S.P.Q.2D (BNA) at 1108. The court then concluded that "the analysis in Sage Products casts grave doubt over the validity of the analysis and conclusion of this Court in its Summary Judgment Order." The district court further noted this court's decision in Ethicon Endo-Surgery, Inc. v. United States Surgical Corp., 149 F.3d 1309, 1321, 47 U.S.P.Q.2D (BNA) 1272, 1280 (Fed. Cir. 1998), in which we held that a "subtle difference in degree, not a clear substantial difference or difference in kind" precluded summary judgment on the issue of DOE. As a result, the district court found that it had erred in submitting the issue of DOE infringement to the jury.

The district court also conditionally granted a new trial on damages and a new trial on infringement in the event this court finds that Hoffinger had waived its right to seek JMOL. Exercising its discretion under Rule 50, the court found that "the award [amount] of damages is so large in light of the evidence of record that the verdict does 'shock the conscience of the court.'" The court specifically noted that the jury had erroneously awarded Zodiac lost profits in an amount equal to that of the three alternative lost profits calculations offered, as well the total of the three alternative prejudgment interest calculations and the total of the three alternative reasonable royalty calculations.

On the issue of attorney's fees, the court found that "the Plaintiff and its expert had a good faith argument that the structure of Defendant's cleaners infringed based upon their analysis of the water flow in the accused cleaners." Accordingly, the district court denied Hoffinger's request for a fee award.

Zodiac now appeals the district court's summary judgment on literal infringement of the '382 patent, the court's grant of JMOL on the issue of infringement of the '382 patent under the DOE and the court's conditional new trial rulings. Hoffinger cross-appeals the district court's refusal to award it attorney's fees as to the claims surrounding the '068 patent. This court has jurisdiction over the appeals under 28 U.S.C. § 1295(a) (1994).

II.

To establish whether an accused device infringes a patent, this court performs a two-step analysis. "First, the claims must be correctly construed to determine the scope of the claims. Second, the claims must be compared to the accused device." Kahn v. General Motors Corp., 135 F.3d 1472, 1476, 45 U.S.P.Q.2D (BNA) 1608, 1610 (Fed. Cir. 1998) (citations omitted). Claim construction is a question of law, which we perform without deference to the trial court. See Cybor Corp. v. FAS Techns., Inc., 138 F.3d 1448, 1454-56, 46 U.S.P.Q.2D (BNA) 1169, 1172-75 (Fed. Cir. 1998); Markman v. Westview Instruments, Inc., 52 F.3d 967, 979-81, 34 U.S.P.Q.2D (BNA) 1321, 1329-31 (Fed. Cir. 1995), aff'd 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). As for the second step, we must affirm a jury's determination that the accused device or process contains each limitation of the claim if that determination is supported by substantial evidence. See Seal-Flex, Inc. v. Athletic Track & Court Constr., 172 F.3d 836, 842, 50 U.S.P.Q.2D (BNA) 1225, 1228 (Fed. Cir. 1999).

We begin with the issue of claim construction. The meaning of the claims at issue in this case is largely undisputed. The parties agree that the claims include four separate limitations, and that the first three of these are included in Hoffinger's devices. What is disputed is the meaning of the fourth limitation, limitation (d), and whether this limitation reads on a corresponding element in either the "Cruiser" or the "Glider." As noted earlier, limitation (d) reads as follows: "a stop for preventing upward flexing of the peripheral edge beyond a predetermined amount located forward of the body and above and substantially inward of the peripheral edge." The parties disagree as to whether this limitation includes a stop that extends at least to the peripheral edge of the flexible disc, and perhaps beyond.

When construing the meaning of a claim, the court may consider both intrinsic and extrinsic evidence. Intrinsic evidence consists of the claim itself, the specification, and any prosecution history. Extrinsic evidence includes expert testimony, inventor testimony, dictionaries, treatises, and prior art not cited in the prosecution history. The court turns to extrinsic evidence only when the intrinsic evidence is insufficient to establish the clear meaning of the asserted claim. See generally Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-84, 39 U.S.P.Q.2D (BNA) 1573, 1576-78 (Fed. Cir. 1996).
Zodiac argues that when the district court construed limitation (d), it ignored the intrinsic evidence surrounding the patent. According to Zodiac, limitation (d) recites a stop that is sufficiently rigid to prevent the leading edge of a cleaner's disc from flexing upward. The stop may take the form of any mechanical structure capable of stopping the disc, and must be located on the front or leading side of the body. Most importantly, continues Zodiac, only some of the structure must be inside the peripheral edge of the disc in order to prevent the flexing of the disc. Thus, **Zodiac contends that the district court erred when it found that all of the structure must be "substantially inward of" the disc's periphery.**

We disagree. First, the language of the limitation itself provides for a "stop . . . located . . . substantially inward of the peripheral edge." It defies common usage to suggest that a stop which is "substantially inward" of an edge could at the same time extend at least to that same edge. Zodiac contends that as long a substantial portion of the stop is in fact inward of the edge, both conditions could be satisfied. This contention, however, ignores that the limitation recites a relationship between the edge and the stop, not a relationship between the edge and a portion of the stop.

Second, the prosecution history confirms this interpretation. As originally claimed, element "d" recited only a "a stop located forward and above the body and inward of the periphery of the flexible disc." The Examiner rejected the limitation under 35 U.S.C. § 102(b) (1994), in light of the KK '227 patent, which included a flange that could act as a "stop." In response to the Examiner's suggestion, the applicant initially tried to distinguish the KK '227 patent without changing the claim. The Examiner, however, rejected the distinction, and made the rejection final after noting that "the upper flange of [the Kreepy Krauly '227 patent] could well function as a stop. Nothing in the claims defines a stop-flange periphery relationship as argued by applicant."

Thereafter, the applicant amended the claim to include not only a stop capable of performing the function, but also a stop located "substantially inward" of the disc's peripheral edge. After the amendment, the Examiner allowed the claim. Thus, the applicant obtained the patent only after he disclaimed a relationship between the stop and the disk's edge that permitted the stop to extend up to and beyond the edge. As the applicant himself noted, he made the disclaimer "to more distinctly define the subject matter applicant regards as the invention and to claim the structure of the invention with greater specificity. Applicant submits that the claims now define a stop/disk periphery relationship not disclosed in [the Kreepy Krauly '227 patent]."

I respectfully dissent from the portions of this court's judgment upholding the district court's summary judgment of no literal infringement and overturning the jury's verdict of infringement under the doctrine of equivalents. I concur with the court's disposition of the other issues in the case.

This court's rulings on both infringement issues are based mainly on the court's interpretation of the phrase "substantially inward of the peripheral edge [of the flexible disc]" in claim 1 of the '382 patent. According to the court, the word "substantially" must be interpreted to mean "very much" or "far," so that the quoted phrase means "very much inward, or far inward of the peripheral edge of the flexible disc." The word "substantially," however, has another meaning: it can, and often does, mean "largely," "essentially, or "in the main." See Webster's New 20th Century Dictionary 1817 (1983); Webster's New World Dictionary of the American Language 1454 (1962); see also Black's Law Dictionary 1428 (6th ed. 1990) ("essentially, without material qualification, in the main"); Webster's Ninth New Collegiate Dictionary 1176 (1983) ("largely but not wholly that which is specified"); 1176 (1983) ("largely but not wholly that which is specified"); York Prods. Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1573, 40 U.S.P.Q.2D (BNA) 1619, 1622 (Fed. Cir. 1996). Under that interpretation of the term "substantially," the phrase "substantially inward of the peripheral edge of the flexible disc" would mean "mostly or mainly inward of the peripheral edge of the flexible disc."

Because the term "substantially" can have either meaning, we must look elsewhere to determine which meaning should be adopted in this instance. When we do, we find that the claim language, the written description, and the prosecution history all point the same way: the term "substantially" should be interpreted, as Zodiac proposes, to mean "largely," "mostly," or "in the main," rather than "far."

1. The claim. The stop would not serve the function that the patent envisages if it were positioned far inward of the edge of
the flexible disc. The stop needs to be near the edge of the disc in order to perform the claimed function of "preventing upward flexing of the peripheral edge beyond a predetermined amount." If the stop is located far inward of the periphery of the disc, the edge of the disk will flex upward without restriction, creating many of the very problems that the patent was intended to overcome. Therefore, the language of the claim supports Zodiac's interpretation of the term "substantially."

2. The written description. The written description explains that the "retainer," which forms the stop, "is located a short distance above and adjacent the edge of the disc," and the stop "prevents the disc . . . from flexing upwardly relative to the foot by more that a predetermined amount." Col. 3, ll. 37-39. Thus, the patent makes clear that the stop is not located far inward of the peripheral edge of the disc, but is "adjacent" to the edge of the disc. For that reason, the written description is consistent with Zodiac's interpretation of the pertinent claim language.

3. The prosecution history. As originally drafted, claim 1 of the application contained language that read: "a stop is located forwardly of the body, a short distance above, and inwardly of, the periphery of the flexible disc." The examiner rejected that claim, in part on the ground that it was anticipated by U.S. Patent No. 4,023,227 to Chauvier. The examiner took the position that a flange that protruded slightly from the body of the cleaner in Chauvier was a "stop." The applicant rewrote the claim, including the following as limitation (d): "a stop located forward and above the body and inward of the periphery of the flexible disc." The applicant argued that the new claim was not anticipated by the Chauvier patent, as the flange recited in Chauvier "does not act to prevent the disc from flexing a predetermined amount . . . . [It] cannot prevent the periphery of sealing flange 34 [i.e., the flexible disc] from upward flexing." By contrast, the applicant continued, the stop recited in limitation (d) of the new claim "is suspended above and not connected to [the flexible disc] and thus prevents the periphery of [the flexible disc] from flexing upward more than a predetermined amount."

The examiner persisted in his rejection on several grounds, including that the claim as drafted was anticipated by Chauvier, that "the utility of said stop has not been developed in the claims," and that "nothing in the claims defines a stop-flange periphery relationship as argued by applicant." After a telephone interview, the applicant amended the language of limitation (d) by including the functional language "for preventing upward flexing of the peripheral edge beyond a predetermined amount," and by making the location of the stop more specific by reciting that it was "located forward of the body and above and substantially inward of the peripheral edge." The applicant explained that "the claims now define a stop/disk periphery relationship not disclosed in Chauvier." In that amended form, the claim was allowed.

Both the examiner's rejection in light of Chauvier and the amendment made by the applicant support Zodiac's interpretation of the pertinent claim language. If the term "substantially inward" is interpreted to mean "far inward," the claim language necessarily reads on the flange recited in Chauvier, since that flange is located far inward of the peripheral edge of Chauvier's flexible disc. Moreover, the function recited in the functional clause of the amended limitation was performed by the structure recited in the rest of the limitation. That is, the stop was located "substantially inward of the peripheral edge" of the flexible disc in order to prevent the upward flexing of the peripheral edge of the disc. But that congruence between structure and function obtains only if the word "substantially" is understood in this context to mean "mostly" rather than "far," because a stop located far inward of the peripheral edge would not prevent the upward flexing of the peripheral edge of the disc. Thus, Zodiac's interpretation of the claim is entirely consistent with, and indeed compelled by, the applicant's position before the Patent and Trademark Office. I would therefore construe claim 1 of the '382 patent to require that the stop be located mainly inward of the peripheral edge of the flexible disc, but not far inward of the edge of the disc.

3917

Exhibit Substantially Larger Effective Cutting Face Backrake Angles

Claims in the '249 and '715 Patents require the drill bit to exhibit "substantially larger," "substantially more negative," or "substantially less aggressive" effective cutting face backrake angles. '249 Patent col. 8:60-61; '715 Patent col. 20:25-27, col. 25:4-6. Baker Hughes argues these terms mean "that each effective cutting face backrake angle is to a great extent larger as measured backward from a line placed perpendicular (at a ninety degree angle) to the formation to be cut by the cutter in the intended direction of drill bit rotation." ReedHycalog contends these terms do not require construction.

The dispute centers on the construction of "substantially." A lay jury will understand what "substantially" means, and therefore the term does not require construction.
The mere use of a term like "substantially" to modify a term in a claim does not render a claim indefinite. In Andrew Corp. v. Gabriel Elec., Inc., 847 F.2d 819, 821 (Fed. Cir. 1988), the Federal Circuit explained that terms like "approach each other," "close to," "substantially equal," and "closely approximate" are "ubiquitous in patent claims. Such usages, when serving reasonably to describe the claimed subject matter to those of skill in the field of the invention, and to distinguish the claimed subject matter from the prior art, have been accepted in patent examination and upheld by the courts." SciMed argues, however, that the term "substantially larger" is fatally indefinite because it is a comparative term that fails to identify with any precision how much larger the first transverse dimension of the distal section must be. It states that even ACS' definitions of the term have varied, with ACS stating that the term requires a difference of about twenty percent and Mr. Corso stating that the difference would be "on the order of 15 percent or bigger." Flannery Dec., Ex. 17 at 494:25-26.

SciMed's arguments are unavailing. As the Court previously observed, figure three, which depicts a cross-sectional dimension that is about twenty percent larger than a perpendicular cross-sectional dimension, provides an indication of the scope of the term "substantially larger." See December 24, 1998 Order at 18; Hansen Dec., Ex. 38 at 20 ("As depicted in Figure 3, the embodiment of Figures 1-5 has a cross-sectional dimension that is approximately 23% larger than a perpendicular cross-sectional dimension."). Figure nine also depicts a cross-sectional dimension that is approximately twenty percent larger than a perpendicular cross-sectional dimension. 6 See Hansen Dec., Ex. 28 at 21. In addition, as the Court also previously noted, the specification clearly states that the purpose of reducing the catheter profile, which results in one transverse dimension substantially larger than the perpendicular direction, is to increase flexibility substantially. Thus, the specification makes clear that the difference between the first transverse direction and the perpendicular direction must be such as to result in a substantial increase in flexibility. The Court concludes that this requirement, in connection with figures three and nine, allows a person skilled in the art to ascertain the scope of the Sirhan '275 patent.

6 The Federal Circuit has held that "drawings alone may provide a written description of an invention as required by § 112." Wang Labs., Inc. v. Toshiba Corp., 993 F.2d 858, 866 (Fed. Cir. 1993) (internal quotation marks omitted).
"Substantially less," thus, means considerably less in extent. The patentee has characterized differences of 10% as "slightly less." See col. 6, ins. 26-29.

D. "Substantially Linear Body Portion"

"Substantially linear body portion" is used in several claims at issue. (Doc. 29, Ex. A). Dentsply argues that "body portion" refers only to a part of the overall "tip." (Docs. 34, 55). Hu-Friedy contends that the phrase should be construed as synonymous with "tip." (Docs. 52, 55).

The claim language clearly supports Hu-Friedy's position. The claims describe the "body portion" as "having a fluid inlet end[and] a subgingival outlet end." (Doc. 29, Ex. A). "Fluid inlet end" refers to the region extending from the discharge orifice to the proximal point of the tip. 4 "Subgingival outlet end" means the region of the tip extending from the discharge orifice to the distal point of the tip. 5 These two "ends" encompass the entire "tip." By describing "body portion" as also encompassing both of these ends, the claims link the phrases "body portion" and "tip."

4 See supra Part II.C.
5 The parties agree on this construction. (Doc. 50).

Other claims confirm that "body portion" and "tip" are equivalent. Several claims instruct that the tip should be bent to form an angle with the "longitudinal center axis" of the "body portion." Other claims describing the same process provide that the tip should be bent to form an angle with the "longitudinal center axis" of the "tip." These claims clearly equate "body portion" and "tip," and others similarly match "body portion" with "tip body." The claims use these phrases interchangeably and they should receive a similar construction.

This interpretation is further bolstered by the specifications section. The patent does not differentiate between "tip," "tip body," and "body portion" in describing the preferred embodiments of the device. Instead, the specifications repeatedly use the terms "tip" and "body" to refer to the same metal piece, which is bent and drilled to form the finished invention.

This construction also finds support in dictionaries. "Tip," "body," and "portion" all refer to an object that encompasses a certain spatial region. 6 AMERICAN HERITAGE COLLEGE DICTIONARY 1443 (4th ed. 2002); MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY 1233 (10th ed. 2002). Interpreting them synonymously fits with the patentee's language and reference definitions. The court will construe "substantially linear body portion" as "a tip extending in a substantially straight line."

6 See also supra Part II.A.

The claims of the '196 patent which are at issue are directed to methods and a device for bleaching teeth. After the '196 patent issued, Dunhall filed complaints against Discus Dental, Inc. ("Discus") and its president, Robert Hayman, as well as Interdent, Inc. ("Interdent") and its president, Kenneth Rosenblood, in the United States District Court for the District of
Colorado alleging infringement of all fifty-nine claims of the '196 patent. The cases were consolidated and transferred pursuant to motion to the United States District Court for the Central District of California (the "district court"). After some discovery, Dunhall filed a third complaint alleging infringement of claims of the '196 patent against Westside Packaging, Inc. ("Westside"), Laclede Professional Products, Inc. ("Laclede"), the corporate dental practice of William M. Dorfman, and William M. Dorfman himself. The district court consolidated these three lawsuits.

Discus and Interdent market take-home teeth whitening kits containing compositions used for bleaching teeth surfaces and materials for making bleaching trays that fit over a patient's teeth. The material used by the alleged infringers in making dental bleaching trays is 0.04 inch thick ethylene vinyl acetate ("EVA"). This material is a relatively more pliable plastic as compared to vinyls, polycarbons, styrenes, and polyvinyl chlorides. Discus sells its kits to dentists and Interdent sells its kits to distributors, who in turn market the products to dentists. Laclede manufactures the compositions used in the take-home bleaching kits of Discus and Interdent. Westside assembles and packages all of Discus's and Interdent's tooth whitener kits.

Dr. Dorfman uses the tooth whitening products on patients in his corporate practice.

The '196 patent is a reissue of U.S. Patent No. 4,990,089 (the "'089 patent"). Within one month of the issuance of the '089 patent, two separate declaratory judgment actions ("DJs") seeking invalidity and non-infringement were filed against Dunhall. As a consequence of these actions, Dunhall filed the '196 reissue application on August 7, 1991. In view of the filing of the reissue application, the DJs were dismissed.

The prosecution history of the '196 patent includes deposition transcripts from the DJs, three prior art statements, the original reissue declaration and fourteen supplemental reissue declarations. In other words, the prosecution history is quite voluminous. During the reissue proceeding, the claims were amended and subsequently allowed. 1

--- Footnotes ---

1 Claims 33 and 34 are dependent on claim 30, which provides:

30. The use of a composition capable of sustained nascent oxygen release to brighten teeth, wherein the use comprises:

bringing said composition into physical contact with a sufficient portion of the surface of each tooth to be brightened for a sufficient amount of time to effect substantial brightening of said tooth; and

retaining said composition by a mechanical barrier around said composition, said mechanical barrier being substantially liquid tight.

Claim 37 is dependent on claim 36, which provides in pertinent part:

36. The use of a thin plastic splint in a process to accomplish substantial brightening of a tooth or teeth, comprising:

(a) placing within a custom fitted and trimmed, thin plastic splint . . . said thin plastic splint custom-formed and adapted to said tooth or teeth so as to be in substantially liquid tight engagement when in engagement with said tooth or teeth . . ."

--- End Footnotes ---

After conducting a Markman hearing, the district court entered an Order on September 4, 1998, construing among other terms "substantially liquid tight," and "mechanical barrier." The court stated:

Where a device is described as being "substantially liquid tight" in the '196 patent, that description shall be interpreted as meaning a rigid, custom fitted appliance which fits over a patient's teeth and extends onto and forms a seal with the patient's gingiva.

The term "rigid" shall be interpreted as meaning that the device must be as firm as possible, while still being sufficiently resilient to allow the device to be removed and replaced around the teeth and gingiva . . . .

The term "substantially liquid tight mechanical barrier" shall have the same meaning, and contemplate the same device,
as the term "substantially liquid tight splint."

Subsequent to that Order, Dunhall limited its claim of infringement to claims 33, 34, 37, 47, and 48 of the '196 patent. The parties also stipulated to the dismissal of Laclede from the case. The remaining Defendants moved for summary judgment of non-infringement contending that: (1) the custom formed trays used in their kits do not possess a sufficient degree of rigidity to fall within the scope of the term "substantially liquid tight splint" and "mechanical barrier," as construed by the district court; and, (2) their trays do not engage patients' gingiva.

The district court did not decide the summary judgment motion on the basis of the gingival engagement, specifically noting that there was a material question of fact as to whether or not the Defendants' tray engaged the gingiva. 2 Instead, the district court granted Defendants' motion that they do not literally infringe based on its conclusion that each of the asserted claims of the '196 patent requires a "rigid" splint and the Defendants' trays do not fall within its definition of "rigid." As for infringement under the doctrine of equivalents, the court found that the Defendants' trays were soft, flexible trays. The court also determined that prosecution history estoppel prevented Dunhall from recapturing a claim scope that would encompass soft, flexible trays through the doctrine of equivalents. Thus, the district court determined that there could be no infringement by the Defendants' trays under the doctrine of equivalents.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 In view of this determination by the district court, we do not address the parties' comments or arguments regarding gingival engagement of the Defendants' trays.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Following the entry of Final Judgment, Defendants moved for an award of attorneys' fees. The district court denied that motion finding that the case was not exceptional under 35 U.S.C. § 285.

Dunhall appeals from the Final Judgment entered by the district court in favor of Defendants and Defendants cross-appeal from the district court's denial of their motion for attorneys' fees. We have jurisdiction under 28 U.S.C. § 1295(a)(1).

DISCUSSION

Standard of Review

In considering a motion for summary judgment, a district court must decide "if the pleadings, depositions, answers to interrogatories, and admissions on file, together with the affidavits, if any, show that there is no genuine issue as to any material fact and that the moving party is entitled to a judgment as a matter of law." Fed. R. Civ. P. 56(c); see also Celotex Corp. v. Catrett, 477 U.S. 317, 322, 91 L. Ed. 2d 265, 106 S. Ct. 2548 (1986). On appeal, we apply this standard anew, without any deference to the determination of the district court. See Zodiac Pool Care, Inc. v. Hoffinger Indus., Inc., 206 F.3d 1408, 1416, 54 U.S.P.Q.2D (BNA) 1141, 1146 (Fed. Cir. 2000). In addition, we draw all reasonable inferences in favor of the non-movant. See Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 255, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986). In view of the foregoing, when we review a district court's grant of summary judgment of non-infringement, we must determine whether the district court correctly concluded that no reasonable jury could find infringement. See IMS Tech. Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1429, 54 U.S.P.Q.2D (BNA) 1129, 1133 (Fed. Cir. 2000).

When reviewing whether an accused device infringes a patent claim, we perform a two-step analysis. "First, the claims must be correctly construed to determine the scope of the claims. Second, the claims must be compared to the accused device." Kahn v. General Motors Corp., 135 F.3d 1472, 1476, 45 U.S.P.Q.2D (BNA) 1608, 1610 (Fed. Cir. 1998).

Analysis

I. Claim Construction

"The construction of claims is simply a way of elaborating the normally terse claim language in order to understand and
explain, but not to change, the scope of the claims." Embrex, Inc. v. Service Eng'g Corp., 216 F.3d 1343, 1347, 55 U.S.P.Q.2d (BNA) 1161, 1163 (Fed. Cir. June 28, 2000) (internal quotations and citation omitted). Interpreting the asserted claims begins with a review of the intrinsic evidence, which consists of the claim language, the specification, and the prosecution history. See id.; see also Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2d (BNA) 1573, 1576 (Fed. Cir. 1996). If the intrinsic evidence resolves any ambiguity in a disputed claim, extrinsic evidence cannot be used to contradict the established meaning of the claim language. See Mantech Envtl. Servs., Inc. v. Hudson Envtl. Serv., Inc., 152 F.3d 1368, 1373, 47 U.S.P.Q.2d (BNA) 1732, 1736 (Fed. Cir. 1998). Extrinsic evidence may, however, be accepted by the court to enhance its understanding of the technology. See EMI Group N. Am., Inc. v. Intel Corp., 157 F.3d 887, 892, 48 U.S.P.Q.2d (BNA) 1181, 1184 (Fed. Cir. 1998).

As to the review of the intrinsic evidence, the specification is reviewed to determine whether the patentee used terms in a manner inconsistent with their ordinary meaning. See Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2d (BNA) at 1577. The prosecution history is considered to determine whether or not there were any express representations made in obtaining the patent regarding the scope and meaning of the claims. See id.; see also Southwall Techs., Inc. v. Cardinal IG, Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2d (BNA) 1673, 1676 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution.")

As set forth above, the district court noted that the term "'substantially liquid tight mechanical barrier' shall have the same meaning, and contemplate the same device, as the term 'substantially liquid tight splint.'" Moreover, the district court construed the term "substantially liquid tight" as meaning "a rigid, custom fitted appliance which fits over a patient's teeth and extends onto and forms a seal with the patient's gingiva." Additionally, the court defined "rigid" as "meaning that the device must be as firm as possible, while still being sufficiently resilient to allow the device to be removed and replaced around the teeth and gingiva."

A.

Dunhall contends that the district court's claim construction is erroneous because, in the first instance, it interpreted the term "substantially liquid tight" to require a "rigid" appliance. Dunhall notes that the term "substantially liquid tight" is defined in the '196 patent specification as:

engagement between a custom-made splint and the teeth/tooth effectively tight to (a) minimize saliva from impacting the teeth/tooth enclosed within the splint, (b) restrain physically the cleaning/brightening solution from evaporating or migrating away from the teeth, and (c) prevent the destruction of the oxygenation properties of the peroxide.

'196 patent, col. 3, ll. 39-46. Dunhall also notes that the term "rigid" does not appear in that definition or anywhere else in the specification, and therefore, cannot be applied to limit the definition of the term "substantially liquid tight." In view of the foregoing, Dunhall concludes that it was error for the district court to apply any other definition to the term "substantially liquid tight" than that which is set forth in the specification.

These arguments are not persuasive. The mere fact that a specific definition of a claim term is set forth in the specification does not mean that the prosecution history should be ignored in construing the claims. The exchange between the patentee and the patent examiner often reveals representations made in obtaining the patent from the Patent and Trademark Office ("PTO") regarding the scope and meaning of claim terms, even those with definitions provided for in the specification. In other words, whether or not a specific definition of a term is present in the specification, "the prosecution history (or file wrapper) limits the interpretation of claims so as to exclude any interpretation that may have been disclaimed or disavowed during prosecution in order to obtain claim allowance." Standard Oil Co. v. Am. Cyanamid Co., 774 F.2d 448, 452, 227 U.S.P.Q. (BNA) 293, 296 (Fed. Cir.1985). Therefore, interpreting claims requires a review of all of the intrinsic evidence: the claim language, the specification, and the prosecution history.

Dunhall contends that even considering the prosecution history, limiting the interpretation of "substantially liquid tight" to "rigid" custom-fitted appliances is erroneous, because the prosecution history does not evidence a deliberate and unequivocal surrender of non-rigid custom-fitted appliances. In support of this position, Dunhall notes that the Examiner did not require the term rigid to be added to the claim language and that the Examiner's reasons for allowance did not include any rigidity aspect to the "splint." Therefore, Dunhall concludes that a reasonable competitor would not understand the claims to be restricted to a "rigid" appliance. As additional support for this position, Dunhall also asserts that the defendant
Discus' patent attorney, after a thorough review of the '196 file history, did not read any "rigidity" requirement into the splint, but rather, stated that the term "substantially liquid tight" should be construed according to the express definition set forth in the '196 patent specification.

We do not find any of these arguments to be persuasive. First of all, Dunhall's last contention is simply untrue. In an opinion letter dated April 27, 1994, Discus' attorney noted that the first step in an infringement analysis is to interpret the claims. In so doing, the attorney noted that "during prosecution of the application which issued as the '196 Munro patent, attorneys for Dunhall differentiated what they considered to be their 'splint' from the prior art 'trays' or 'mouthguards' by taking the position that prior art devices were rubbery or soft and that the splint defined by the claims of the application was rigid." (emphasis added.) Accordingly, the record reveals that Discus' attorney in fact understood the claims to be limited to a "rigid" splint, contrary to the representation made to the court by Dunhall's counsel. 3

3 The court notes its strong disapproval of counsel's careless, and in this case inaccurate, representations of the facts surrounding this issue to the court. Counsel does not serve the best interests of his client in presenting to this court arguments that reflect less than rigorous respect for the truth and accuracy of the record before us.

As to Dunhall's contentions regarding the Examiner's reasons for allowance, and his not requiring that the limitation "rigid" be added to the claims, while such information facilitates evaluation of the scope of the claim, it is not dispositive of what the specific terms of the claims mean. The prosecution history is not limited merely to the Examiner's remarks; it includes the entirety of the interchange between the Examiner and the applicant in the course of prosecuting the application to allowance.

Our review of the prosecution history reveals that the '196 patent file history contains several representations regarding the support structure that engages the tooth/teeth in a "substantially liquid tight" manner, i.e., the "splint" (claims 34, 37, 47, 48) or "mechanical barrier" (claim 33). In the Statement of Prior Art and Other Information received by the PTO on August 7, 1991, Dunhall specifically stated that the " '089 specification teaches a rigid, individually molded, close-fitting support structure around one or more teeth. Similar vacuum-formed acrylic splints are described in detail in THE COLOR ATLAS OF PERIODONTOLOGY by Raitetschack et al. in their chapter on 'Splinting,' at pp. 291-296. The concept of 'splinting' was developed to form close-fitting rigid individually formed supports for stabilizing mobile teeth." (emphasis added). In this same document, Dunhall also stated that "splinting . . . by definition requires 'rigidity,' [and such rigidity] is inconsistent with the 'resiliently flexible trays of Greenberg '219 . . . or the 'spoon like core' of Riddell '935 . . . " And, "it is clear that the teaching of Munro '089 is utterly inconsistent with the soft trays of Riddell '935 . . . and Greenberg '219 . . . ." Finally, in a supplemental amendment filed by Dunhall with the PTO, Dunhall distinguished the claimed splint from a 1982 Dutch patent application disclosing a "rigid" polyurethane foam or polyethylene foam fluoride tray liner, saying that such liners would be "too soft and pliable and non-durable for extended uses."

The foregoing clearly evinces that, in order to obtain allowance of its application, Dunhall distinguished the claimed "splint" or "mechanical barrier" that engages the tooth/teeth in a "substantially liquid tight" manner as a "rigid" custom-made appliance. In view of this prosecution history, we therefore, conclude that the district court did not err in its conclusion that where a device is described as being "substantially liquid tight" in the '196 patent, that description should be interpreted as meaning "a rigid, custom fitted appliance . . . ."

3922

CLAIM 2

Claim 2 depends from claim 1 and reads as follows, with the disputed language italicized:

"2. A fuel delivery system as set forth in claim 1, wherein said filter media is a paper filter presenting substantially no openings therethrough having a greater dimension than 25 microns."
Plaintiffs assert that the language is not ambiguous and should be construed in accordance with its ordinary meaning. It is unclear whether Defendants are claiming the language is ambiguous or unambiguous; they claim the language is unambiguous - subject to the definition of the filter media proffered by Defendants in claim 1. Based on the prosecution history, which at one place 6 defines the filter media as "having substantially no openings of a greater dimension than about 25 microns for preventing the passage of air," Defendants assert that the language should be construed to mean "a filter media which allows fuel to pass but not undesired gas."

6 Prosecution history of the '860 patent, Amendment, 12/13/93, p. 7, first paragraph.

The Court finds, however, that the language of the claim is unambiguous as written. Consistent with Plaintiffs' proposed construction, one of ordinary skill in the art would understand this term to mean as follows: "the filter media is a paper filter that has substantially no openings through it with dimensions greater than 25 microns." This language is wholly consistent with its use in the specification. See col. 2, lines 21-35; col. 4, lines 25-33; col. 5, lines 26-49; col. 6, lines 21-24. And the Court finds nothing in the specification suggesting a meaning other than the ordinary meaning. Nor does the Court find, from a careful review of the prosecution history, that the definition proposed by Defendants was either offered or necessary to distinguish this claim from the prior art. Indeed, the construction proffered by Defendants is inconsistent with the specification and drawings, which make clear that "substantially" all, but not necessarily "all" the air is separated. See e.g., col. 2, lines 33-34; col. 5, lines 9-10; fig. 3. Moreover, the Court has difficulty imagining, from a technical standpoint, how a paper filter could be porous enough to permit "fuel to pass, but not air," and neither the claims nor the specification suggest the paper filter possesses such a characteristic. Rather, as set forth above, it filters entrained air bubbles.

3923

ff. "Substantially Non-resilient Lever Moving Element" (Claim 3)

157. While this claim element does not use the term "means", it defines an "element" for performing specified functions. Thus, under the principles described above, "element for" is equivalent of "means for".

158. During prosecution of the '656 patent, the applicants amended the language "means for moving the lever" to "a substantially non-resilient lever moving element for moving the lever". PX 45, p. 129. The applicants argued that this change was made "to more clearly define the invention" and "to exclude the force of gravity operating on the lever to constitute the means for moving the lever". PX 45, p. 141. This shows that either the applicants considered "means" to be equivalent to "element", or that they considered "element" to define a narrower scope than "means". However, regardless of the change in terminology, the means-plus-function form of the claim was retained.

159. The terminology "substantially non-resilient lever moving element", "lever moving element", or "moving element" has not been shown to have a generally understood meaning in the art. Cf., Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583 (Fed. Cir. 1996) ("detent mechanism" had well-understood meaning in the field). This "moving element" is described in terms of what it does, i.e. its function ("for moving the lever from its disengaged position"), not in terms of its mechanical structure. Even if the element retains minimal structure, this does not prevent it from being interpreted under § 112 P6. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1536 (Fed. Cir. 1991).

160. The phrase "lever moving" which modifies "element" is itself functional, i.e., it defines the "element" in terms of functionally moving a lever.

161. The modifying term "non-resilient" is also functional in nature since it defines the element in terms of its capability. The term "non-resilient" is not used or defined in the '656 patent specification, but appears for the first time in the claims. This language was added to distinguish from prior art which showed resilient, non-rigid element (i.e. springs) which operated to bias the lever into engagement with the cam wheel. PX 45, p. 113, 130, 155, 173-4, 198-9. The applicants
further argued that their "invention" was different from the prior art because the prior art did not show a lever moved by a rigid element separate from the lever. PX 45, p. 113. Consequently, as used in the '656 patent claims, a "non-resilient lever moving element" is one which does not utilize a spring.

162. The "element" in this claim is also principally defined in terms of three functions: (1) moving the lever from its disengaged position; (2) for engaging the protrusion of the lever with the cam surface on the cam wheel; and (3) so that the rotation of the cam wheel thereafter in the given direction changes the locked mechanism from the locked condition to the unlocked condition.

163. Other claims in the '656 patent show the patentees' intent to use "means" and "element" interchangeably and therefore equivalently to describe the same parts of the lock. Claims 1, 17, 19, 28, ("lever operating means"); Claim 5 ("lever moving means"); Claims 2, 8, 20, 24, 31 ("lever moving element"); Claims 12, 25 ("lever controlling element"). Other claims of the patent may be used to determine the scope of the claim at issue. McGill, Inc. v. John Zink Co., 736 F.2d 666, 674 (Fed. Cir. 1984). These are all the same mechanical structure, described in equivalent functional language, whether using the equivalent terms "means" or "element".

164. In the '656 patent specification, the substantially non-resilient lever moving element includes a cantilever arm which is an integral part of the lever and contains at its lower end a movable spring-loaded detent pin contained within a bore. The lower end of the pin engages a ramped recess in the solenoid housing. Upon entry of the proper combination and upon activation of the solenoid, the solenoid housing translates linearly to release the detent pin from the recess. This action causes the detent pin to move to a second position which pushes the lever into engagement with the dial cam. As the dial is rotated to withdraw the bolt, the lever and associated lower end of the detent pin slides along the upper surface of the solenoid housing. The lower end of the detent pin stays out of engagement with the recess when the solenoid is de-energized. Once the lever is engaged with the cam, the bolt and related assembly move independently of the solenoid housing. By this time, the solenoid housing has been released and returned to its normal position.

D. "points substantially on a geometric extension"

Claim 8 discloses a valve in which the closure member is shaped as a section of a sphere ("a closure member having a regular spherical section curved exterior surface"). Within that claim, the parties dispute the meaning of "points substantially on a geometric extension" in the context of the following limitation:

Each [plate] extends to points substantially on a geometric extension of said regular spherical section curved exterior surface to engage [the] sealing means to provide that fluid flowing in [the] flow passage past [the] closure member, in a partially open position thereof, flows through said plates . . . .

'510 Patent at col. 9, 11. 28-33. If one imagines the surface of the closure member described in claim 8 expanded to create a complete sphere, that imaginary sphere is the "geometric extension" referred to in the claim. This Court must 1) identify the points "substantially" on the geometric extension to which the plates must extend and 2) construe the word "substantially."

1. "points"

Neles argues that the only relevant "points" on that imaginary sphere are the points where edges of the plates "engage [the] sealing means" as the closure member rotates between open and closed positions. Neles contends that

a) claim 8 discloses valves with a single sealing means;

b) a valve with a single sealing means is a "quarter turn valve" and, thus, only rotates 90 degrees;

c) the only relevant points on the imaginary sphere span that 90 degrees; and therefore

d) only one end of each plate must extend "substantially" to the surface of that imaginary sphere.
Fisher argues that the relevant "points" on that sphere comprise complete circles formed by the edges of the plates so that almost all fluid "flowing in [the] flow passage . . . flows through said plates" and not around them. Fisher also points out that

a) the '510 Patent is not limited to quarter-turn valves because the specification describes valves that operate in both directions;

b) in bi-directional valves, the closure member's rotation is 360 degrees; and therefore

c) even plates which trace the pattern of rotation must extend "substantially" to the surface of the imaginary sphere on both ends.

The claim itself states both that 1) the edges of the plates must engage the sealing means and 2) the fluid must flow through the plates. First, in order to engage the sealing means, as both parties agree, the plates must extend close to the surface of the imaginary sphere on at least one end. Second, expert witnesses for both parties confirm that, to the extent the plates do not meet the geometric extension, fluid will leak around the plates. The farther the edges of the plates are from the geometric extension, the greater the leakage.

Describing the "geometric extension," the specification states:

In the embodiments in FIGS 1-12, the barrier means . . . extend[ed] outwardly from either side of the bore to points substantially one [sic] a geometric extension of the curved exterior surface of the closure member. Such a geometric extension is illustrated most clearly in FIGS. 3, 7, and 9. With the barrier means arranged in such a manner, . . . the clearance is small enough that the barrier means very effectively performs its attenuating function in its variable control range.

'510 Patent at col. 3, 11. 63-68 & col. 4, 11. 5-14. Given the expert testimony, in order for the barrier means to "very effectively attenuate" the flow, the plates comprising those barrier means must extend "substantially" to the geometric extension on both ends. The drawings in Figures 1-12 corroborate this interpretation because they depict plates that extend equally on both ends. This Court, therefore construes "points . . . on a geometric extension" to include points at both ends of the plates.

2. "substantially"

Claim 8 is clear that, if plates must extend "substantially" to points in the imaginary sphere which is the "geometric extension," they must extend very close to the surface of that sphere. Expert testimony presented by both parties demonstrated that a person skilled in the art of valve mechanics would understand that some clearance is necessary so that the plates do not scrape the valve casing as they rotate and as temperature fluctuates in the pipe. The undisputed testimony of both Roger Bey, the inventor, and Cullen Langford, NJI's expert, establishes that a person skilled in valve mechanics, would not understand the term "substantially" to require plates to extend as close as humanly possible to the surface of that imaginary sphere because such precision would not be cost-effective.

Based upon the words of the claims and the testimony of the expert and the inventor, this Court construes "substantially" to mean as close as economically efficient allowing for mechanical clearance to avoid contact between the plates and the valve body either through rotation or thermal expansion.

IV. Conclusion

This Court, therefore, concludes with respect to terms as they are used in the '510 Patent that:

1) a "plate" is a structure that is thinner than it is wide or long and that may be flat, curved or twisted and perforated such as a screen or net but that is not a tube;

2) a "barrier means" is any structure, other than the closure member, that attenuates the flow of fluid;
3) "attenuating effect . . . is immediately called into play when said closure member is first opened" means that there is no temporal delay between the opening of the valve and the attenuation of flow;

4) "attenuating effect thereof is great during initial opening" means that over time, while the closure member rotates from a closed to an open position, the attenuation is greater earlier and less later; and

5) "points substantially on a geometric extension" means that attenuator plates must extend on both ends as close to the surface of the imaginary sphere formed by expanding the curved surface of the closure member as economically efficient, allowing for mechanical clearance to avoid contact between the plates and the valve body either through rotation or thermal expansion.

3) "attenuating effect . . . is immediately called into play when said closure member is first opened" means that there is no temporal delay between the opening of the valve and the attenuation of flow;

4) "attenuating effect thereof is great during initial opening" means that over time, while the closure member rotates from a closed to an open position, the attenuation is greater earlier and less later; and

5) "points substantially on a geometric extension" means that attenuator plates must extend on both ends as close to the surface of the imaginary sphere formed by expanding the curved surface of the closure member as economically efficient, allowing for mechanical clearance to avoid contact between the plates and the valve body either through rotation or thermal expansion.

F. "substantially only backscattered light" 30

30 The phrase "substantially only backscattered light" is used in claim 6 of the '259 patent.

1. ADE's Position

ADE argues that "substantially only backscattered light" should be construed to mean "light generally scattered in the backward direction." (D.I. 613 at 19.) ADE offers little supporting its proposed construction of this phrase other than a plain-and-ordinary-meaning argument. (Id.)

2. KLA's Position

Consistent with its argument as to the phrase "oblique zone" and the magistrate judge's prior construction of that phrase, KLA suggests that the phrase "substantially only backscattered light" should "be construed to mean 'only backscattered light.'" (D.I. 594 at 21.) Alternatively, KLA proposes that if the Court cannot "reconcile the recited claim language with the clear teaching of the specification and prosecution history" the Court can invalidate the dependent claim in which the phrase appears under 35 U.S.C. § 112, P 4. 31

3. Analysis

Given this Court's construction of the phrase "oblique zone," supra at 23-37, the Court is compelled to construe the phrase "substantially only backscattered light" to mean that only backscattered light is collected.
5. Claim 1(b.2): Lamp Support Surfaces

5.1 The Claim Language of Claim 1(b.2)

(b.2) said lamp support means including at least two lamp support surfaces on said lamp support means on opposite sides thereof and angled toward the base end of said reflector means for causing compact fluorescent lamps supported thereby to extend outwardly at an angle from said center line toward the light-emitting end of said reflector means to substantially parallel said reflector means; and

5.2 Claim Interpretation Analysis: Applicability of § 112, P6

The "lamp support means" includes two or more "lamp support surfaces" which form a part of the lamp support means itself as indicated by the statement that they are mounted "on said lamp support means."

The description that each "lamp support surface" is "angled toward the base end of said reflector means" means that the "surface" is angled upward relative to a horizontal plane relative to the "side" of the "lamp support means" to which the "lamp support surface" is connected.

The phrase "for causing compact fluorescent lamps supported thereby to extend outwardly at an angle from said center line toward the light-emitting end of said reflector means" means that the compact fluorescent lamps supported by each angled lamp support surface extend outwardly at an angle spaced apart from the reflector centerline as the lamps extend in a downward direction away from the lamp support surface toward the light emitting end of the reflector means. This is precisely the type of angular deflection of the compact fluorescent lamps relative to the reflector centerline as illustrated in the cross sectional views shown in Figs. 3 and 15. The lamp support means mounts the compact fluorescent lamps at locations both laterally spaced away from the reflector centerline and angled away from the reflector centerline.

Interpretation of the Claim 1(b.2) phrase "to substantially parallel said reflector means" limitation requires careful consideration of the Federal Circuit's Vitronics guideline that a claim be interpreted to encompass the preferred embodiments disclosed in the patent in the absence of convincing evidence to the contrary.

The intrinsic evidence, which is far more significant than one might initially realize, dictates in a very subtle way how this claim limitation should be interpreted.

First, as to the written description, very little guidance as to the interpretation of this "substantially parallel" claim limitation is provided. In the Abstract, Tickner states that his inventive design functions to orient the compact fluorescent lamps such that they "follow the outwardly-flared inside surface of the reflector." At Column 5, lines 28-33, Tickner states the following:

As illustrated in FIGS. 3, 4 and 5, the plate 26 is octagonal in shape, and includes, on each of its outer edges, an extension tab or lamp mounting surface 28 onto which a conventional socket 40 is attached for receiving a commercially available push-in compact fluorescent lamp 45. As illustrated most clearly in FIG. 3, the tabs 28 are bent upwardly (as viewed in FIG. 3) approximately 20 degrees to 30 degrees from the plane of the plate 26 to cause the lamps 45 to extend along a line generally following the curvature of the inside of the reflector portion 14B.

At Column 8, lines 57-63, Tickner describes the intended relationship as follows:

As illustrated in FIGS. 3, 4 and 5, the plate 26 is octagonal in shape, and includes, on each of its outer edges, an extension tab or lamp mounting surface 28 onto which a conventional socket 40 is attached for receiving a commercially available push-in compact fluorescent lamp 45. As illustrated most clearly in FIG. 3, the tabs 28 are bent upwardly (as viewed in FIG. 3) approximately 20 degrees to 30 degrees from the plane of the plate 26 to cause the lamps 45 to extend along a line generally following the curvature of the inside of the reflector portion 14B.

At Column 10, lines 56-60, Tickner describes the intended relationship as follows:
The off-center location of the lamps and their orientation substantially parallel to the interior of the reflectors produces light emanating from the reflectors at significantly greater angles than is possible from a single lamp centered in the reflector.

Federal Circuit authority provides some additional claim interpretation guidelines relevant to this claim limitation. In Anchor Wall Systems, Inc. v. Rockwood Retaining Walls, Inc., et al., 340 F.3d 1298, 1311 (Fed. Cir. 2003), the Court commented on the interpretation of a claim limitation expressed as "generally parallel." After noting that the claim language "generally parallel" was mathematically imprecise, the Court explained that

words of approximation, such as "generally" and "substantially," are descriptive 3 terms "commonly used in patent claims to avoid a strict numerical boundary to the specified parameter."

The Federal Circuit cited Andrew Corp v. Gabriel Elecs. Inc., 847 F.2d 819, 821-22 (Fed. Cir. 1988) for the proposition that terms such as "approach each other," "close to," "substantially equal," and "closely approximate" are "ubiquitously used in patent claims and that such usages? when serving reasonably to describe the claimed subject matter to those of skill in the field of the invention and to distinguish the claimed subject matter from the prior art, have been accepted in patent examination and upheld by the courts).

The Federal Circuit stated that in the world of patents and patent law, "while ideally, all terms in a disputed claim would be definitively bounded and clear, such is rarely the case in the art of claim drafting." 847 F.2d 1311.

It is clear from the examination of the Tickner '414 patent written description that not a great deal of specific information was said about the generalized "substantially parallel" relationship between the linear compact fluorescent lamps elements and the obviously curved reflector. In fact, as illustrated in the Fig. 3 cross sectional view of Tickner's first preferred embodiment, the relative angle between the upper or higher level set of compact fluorescent lights and the reflector appears to be fairly parallel to the reflector while the second or lower second set of compact fluorescent lights may be considered to be parallel with a small portion of the upper part of the reflector, but certainly not parallel to the lower portion of the reflector. As to Tickner's second preferred embodiment illustrated in the Fig. 15 cross sectional view, most of the length of the linear compact fluorescent lights is not parallel to any portion of the reflector except potentially the lower extremity of the lamp itself. So how is this apparent claim interpretation dilemma to be resolved?

An historical evaluation of how the intrinsic evidence was created by the patent attorney and then subsequently reviewed by the patent examiner answers this initially puzzling claim interpretation question with great clarity. When the patent attorney wrote the patent application text and drafted the "substantially parallel said reflector means" claim limitation, he would have already received his preliminary version of the patent drawings from his patent draftsman and would have been looking at the pictures of the invention, specifically at the Fig. 3 and Fig 15 cross sectional views -- the only views showing the relationship between the compact linear fluorescent lamps and two different reflector configurations. The patent attorney chose to define the relationship that he observed in those two cross sectional views as defining a special and distinct relationship between the linear compact fluorescent lamps and the illustrated reflector configurations. He defined that visual relationship as representing a lamp-relative-to-reflector orientation which is "substantially parallel to the interior of the reflectors" as plainly stated in the written description and as set forth in the claims. In a sense, the inventor acting through his patent attorney thereby functioned as a lexicographer by defining that "substantially parallel" claim language to generally represent the relationship illustrated in the patent drawing Figs. 3 and 15 which illustrate at least three different examples of that angular relationship. Phillips v. AWH Corp., 415 F.3d 1303, at p. 1319 (an inventor may function as his own lexicographer to specially define his own terms). In other words, this particular claim limitation was defined originally by the patent attorney and the inventor based on a general relationship observed in the patent drawings.

When the Patent Examiner subsequently evaluated the claims for patentability, the Examiner reviewed the same drawings, reviewed the same written description and understood how this "generally parallel" claim limitation had been defined by the patent attorney and the inventor. Based on his understanding and approval, the Examiner passed the claims to issuance.

The most important intrinsic evidence in the Tickner patent takes the form of the Fig. 3 and Fig. 15 drawings, supplemented only slightly by the written description. The appropriate interpretation of "substantially parallel" neither rests on concepts of
geometry nor concepts of parallelism, nor the application of a ruler to a scaled drawing. Instead, the "generally parallel" relationship between a linear compact fluorescent lamp and a curved reflector represents a visual relationship which is both defined in terms of what the language means as well as what is illustrated in the drawings. That specified visual relationship may be applied to an accused structure by viewing a cross sectional view of an accused structure in the form illustrated in Figs. 3 and 15, which presents a scaled relationship between specific compact fluorescent lamps and a vertical section of the reflector lying in a plane defined by two lines: 1) the reflector center line, and 2) the linear axis of the compact fluorescent lamp being evaluated. This is exactly the relationship illustrated Tickner's Fig. 3 and Fig. 15 sectional views.

So, in the context of the present case, because Tickner's patent attorney assisted Tickner to act as his own lexicographer to define almost solely by visual means (rather than by words) the meaning of the "substantially parallel" relationship between the compact fluorescent lamp and an adjacent section of the reflector, the "substantially parallel" relationship represents an "eyeball" definition rather than a textual definition.

This conclusion is both fair and appropriate because, after the Tickner patent issued, the public had access to precisely the same intrinsic evidence originally created by Tickner and his patent attorney. That same intrinsic evidence was subsequently reviewed and understood by the Patent Examiner. After patent issuance, the accused infringer and the public in general was provided access to the same intrinsic evidence. The answer to the claim interpretation puzzle thus lies not in the dictionary, but in the Fig. 3 and Fig. 15 drawings. The resulting visual interpretation fully meets the Federal Circuit's Vitronics dictates that a claim limitation be interpreted to encompass disclosed the preferred embodiments.

That visual or "eyeball" interpretation can be expressed in words as follows:

The "substantially parallel" claim limitation describes the orientation of the compact fluorescent lamp relative to a nearby portion of the reflector.

The portion of the reflector to compare the relative alignment between the reflector and the compact fluorescent lamp can best be visualized by mentally slicing the reflector in half in a slicing direction in alignment with the compact fluorescent lamp.

Fig. 15 of the Tickner patent is referred to as a "cross-sectional view" and illustrates how the appropriate slicing and angular comparing process should be visualized.

A compact fluorescent lamp (such as lamp 45 shown in Fig. 15 of the Tickner patent) is a linear or straight line device that defines one of the two lines to be compared to evaluate whether the compact fluorescent lamp is substantially parallel to the sliced reflector.

The curved exposed edge of the sliced reflector (as illustrated in Fig. 15) from the top of the slice to the bottom of the slice can be thought of as many short, straight reflector segments joined end to end.

If any one of those numerous straight reflector segments located anywhere between the top of the bottom of the reflector slice is "more or less," or "about" or "generally" parallel to the compact fluorescent lamp, then you may find that the compact fluorescent lamp is substantially parallel to the reflector.

The functional limitation for the "at least two lamp support means" relating to "causing compact fluorescent lamps supported thereby to extend outwardly at an angle from said center line toward the light-emitting end of the reflector means to substantially parallel said reflector means" means that, in addition to the various other limitations of the lamp support means previously defined above, a lighting apparatus should include at least two compact fluorescent lamps supported by at least two lamp support surfaces where the compact fluorescent lamps are both 1) laterally spaced away from the reflector center line, and 2) outwardly angled as illustrated in Tickner's patent drawing such that the linear light emitting portion of the at least two compact fluorescent lamps are "substantially parallel" to an adjacent section of the reflector where that "substantially parallel" relationship is defined by Tickner's Fig. 3 and Fig. 15 cross sectional views. The utilization of the modifier "substantially" contemplates meaningful variations from the specific angular relationships illustrated in Tickner's patent drawings as long as the overall "eyeball" impression is one of "general parallelism" as articulated by Tickner's Figs. 3 and 15. Again, that "substantially parallel" relationship can be expressed in words as set forth above.
This relative angular relationship cannot be, as suggested by Sportlite, based on any concept of uniformity of light intensity since Claim 1 no where utilizes that term or invokes that concept.

A. "Substantially Parallel"

The first disputed term of the '079 Patent is "substantially parallel." The '079 Patent teaches that the distal ends of the catheter must "extend substantially parallel to a longitudinal axis of said catheter." (Col. 3, lines 19-20.) Defendants argue that "substantially parallel" means "the same as or very close to parallel." (Def. Mem. at 10.) Plaintiffs argue that defendants' proposed construction is "completely abstract" and "vague," and that "substantially parallel" must be construed in light of functional and exemplary language contained in the specification. (Plaintiffs' Claim Construction Memorandum ("Pl. Mem."), at 10-11.) Plaintiffs argue that the proper construction of "substantially parallel" in the '079 Patent is "that the two end portions, or tips, when disposed within a vascular channel of the body, are sufficiently close to parallel, such that, when the catheter is placed within a body lumen or cavity, the end portions essentially conform to the direction of fluid flow ('like a sail parallel to the wind')." (Pl. Mem. at 18.)

As there is no clearly manifested intent by the patentee to act as his own lexicographer, this Court must look to the plain meaning of the phrase "substantially parallel." Johnson Worldwide, 175 F.3d at 989. In examining that term, plaintiffs' proposed construction violates the plain meaning principle. Further, on a closer review of the intrinsic evidence, it is clear that defendants' proposed construction is appropriate.

"Substantially" is defined as "largely but not wholly that which is specified." Webster's Ninth New Collegiate Dictionary 1176 (9th ed. 1983); accord Shorter Oxford English Dictionary 3091 (5th ed. 2002) ("essentially, intrinsically … actually, really"). It is clear that defendants' proposed construction of "substantially parallel" comports much more closely with the dictionary definition of "substantially" than does plaintiffs' proposal.

Further, the patentee's use of the terms "parallel" and "substantially parallel" interchangeably bolsters the conclusion that the patentee intended the phrase to mean "the same as or very close to parallel." The Abstract, which appears on the first page of the '079 Patent, reads "wherein said end portions, in a rest position of the catheter, extend parallel to the longitudinal axis thereof." When read in conjunction with the corresponding language in the specification and the claim, the patentee's failure to include the modifier "substantially" in front of "parallel" in the Abstract is probative of an intent to use the terms interchangeably. See Amhil Enters. Ltd. v. Wawa, Inc., 81 F.3d 1554, 1559, 1562 (Fed. Cir. 1996) (patentee's use of phrases "substantially vertical" and "vertical" interchangeably in the specification and during prosecution of patent left the "reader with the impression that 'substantially vertical' and 'vertical' mean essentially the same thing"). Plaintiffs' suggestion that it would be error to consider language in the Abstract when construing a claim term (Transcript of Markman hearing, dated April 16, 2003 ("Tr.") at 52) is incorrect as a matter of law. See Hill-Rom Co., Inc. v. Kinetic Concepts. Inc., 209 F.3d 1337, 1341 n.1 (Fed. Cir. 2000) (abstract is part of the intrinsic evidence of a patent, and courts "frequently look[] to the abstract to determine the scope of the invention"). Accordingly, the '079 Patent's use of the phrases "parallel" and "substantially parallel" interchangeably in materially identical contexts militates in favor of construing the term as defendants have proposed, namely "the same as or very close to parallel."

In contrast, plaintiffs' proposed construction of "substantially parallel" impermissibly attempts to import limitations from the specification into the claim, and is undermined by the language of the claim itself. The description in the specification of the distal ends behaving "like a sail set parallel to the wind" is merely a trope, and such examples or representations may not
be read to limit a claim. See Transmatic, 53 F.3d at 1277; Constant, 848 F.2d at 1572; Specialty Composites, 845 F.2d at 987. In addition, plaintiffs' proposed construction of "substantially parallel" seeks to import functional limitations from the specification that do not appear in the claim, such as "when the catheter is placed within a body lumen or cavity, the end portions essentially conform to the direction of fluid flow." 4 (Pl. Mem. at 18.) This is not permissible. See Ecolab, 264 F.3d at 1367; Advanced Cardiovascular Sys., 261 F.3d at 1338-39; Transmatic, 53 F.3d at 1278.

4 In fact, one of the functional limitations that plaintiffs seek to impose on the "substantially parallel" claim -- the requirement that the catheter be "disposed within a vascular channel of the body" -- not only does not appear in the claim, but is nowhere in the '079 Patent.

Finally, plaintiffs' proposed construction is undermined by the language of the claim itself with respect to the proper reference point by which to determine whether the distal ends are parallel. Plaintiffs' proposed construction advocates determining the parallelism of the distal ends in relation to the "direction of fluid flow." 5 The claim itself, however, teaches that a determination of whether the distal ends are parallel must be made in relation to the longitudinal axis of the catheter, and makes no mention of fluid flow. 6 Thus, plaintiffs' proposed construction of "substantially parallel" is improper, and cannot be accepted by this Court.

5 In addition, the Court notes that the "direction of fluid flow" language in the specification does not relate to a determination of whether the distal ends are "substantially parallel" in at least one rest position, but instead refers to the catheter's anti-clogging characteristics. (Compare Col. 2, lines 48-49 with, e.g., Col. 2, lines 36-37.)

6 In addressing this issue during the Markman hearing, plaintiffs again resorted to importing functional limitations into the claim in order to rescue their construction of "substantially parallel." To define the term, plaintiffs suggested that "when the catheter is then implanted in the body cavity that's referred to in the patent, it will be implanted in the direction of that cavity along that axis. So the axis of the catheter is going to match up with the axis of the fluid flow." (Tr. at 32.)

Contrary to plaintiffs' contentions, nothing in Fig. 1 of the '079 Patent, depicting the invention, or in the prosecution history is inconsistent with defendants' proposed construction. (Pl. Mem. at 12-14.) The construction of "substantially parallel" as "the same as or very close to parallel" clearly contemplates the slight deviation from strict parallelism necessitated by the "physical separation" of the distal ends at the "fixed dividing point." (Def. Mem. Ex. B at Arrow 80.) The same analysis applies to the embodiment of the invention depicted in Fig. 1, which shows a slight deviation from parallel at the dividing point, represented at 12 in Fig. 1, with a return to almost strict parallelism as the figure approaches the tips of the distal ends of the catheter, represented at 13A and 14A in Fig. 1. (Col. 3, lines 23-25; Fig. 1). The construction "the same as or very close to parallel," therefore, is not inconsistent with either the prosecution history or the sole embodiment of the invention contained in the '079 Patent. Cf. Johns Hopkins Univ. v. CellPro, Inc., 152 F.3d 1342, 1355 (Fed. Cir. 1998) ("A patent claim should be construed to encompass at least one disclosed embodiment in the written description portion of the patent specification."); ACS Hosp. Sys., Inc. v. Montefiore Hosp., 732 F.2d 1572, 1577 (Fed. Cir. 1984) ("Claims should be so construed, if possible, as to sustain their validity.").

Finally, this Court rejects plaintiffs' contention that defendants' proposed construction of "substantially parallel" is too vague and abstract to provide meaningful guidance. (Pl. Mem. at 10-11; Tr. at 60-61 (describing defendants' proposed construction as an "Olympian abstraction").) Courts need not construe claims to be objectively verifiable in order for a construction to be valid, especially when the claim incorporates the term "substantially." See Ecolab, 264 F.3d at 1367 ("The term 'substantially' is a descriptive term commonly used in patent claims to 'avoid a strict numerical boundary to the specified parameter.'") (quoting Pall Corp. v. Micron Sep., 66 F.3d 1211, 1217 (Fed. Cir. 1995)); Mickowski v. Visi-Trak Corp., 36 F. Supp. 2d 171, 178 (S.D.N.Y. 1999) ("The term 'substantially' has been included merely to bridge the gap between the abstract description of a method and its practical application in the real world.") (vacated, appeal reinstated by 247 B.R. 236...
(Bankr. N.D. Ohio 2000)). Contrary to plaintiffs' contention during the Markman hearing that defendants' citations are "all over the map and quite inconsistent in terms of how close to parallel something is supposed to be" (Tr. at 40), this Court notes that other courts construing "substantially" in similar contexts have reached nearly identical results. See, e.g., Ecolab, 264 F.3d at 1367-69 (holding that "substantially uniform" should be construed as "largely but not wholly in the same form"); LNP Eng'g Plastics, Inc. v. Miller Waste Mills, Inc., 275 F.3d 1347, 1354 (Fed. Cir. 2002) (en banc) ("The claim language supports the correctness of the district court's interpretation of 'substantially completely wetted' as 'largely, but not necessarily wholly, surrounded by resin."); Amhil Enter. 81 F.3d at 1562 (construing "substantially vertical face" as "the same as or very close to 'vertical face'"). Accordingly, this Court construes "substantially parallel" as "the same as or very close to parallel."

3928

Courts must construe disputed claim terms, as a matter of law, based on the claims, the specification, and the prosecution history. Markman v. Westview Instruments, Inc., 52 F.3d 967, 986 (Fed. Cir. 1995) (in banc), aff'd, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). In reaching its decision, the district court focused on two aspects of the parties' competing drying sections. First, the district court examined Valmet's "drying cylinder group" with "two, substantially parallel, rows of drying cylinders," and compared it to Beloit's "single tier drying section" with "two consecutive pluralities of drying cylinders." The court found that Soininen taught a "stacked arrangement" of the two rows of cylinders, while Beloit's patents claimed a "single horizontally disposed plane of dryer cylinders" (emphasis in original). Essentially, the court read Soininen to teach only a sideways U-shaped (i.e., ) arrangement. Meanwhile, the court construed Beloit's asserted claims to refer to a machine that dries one side in the first plurality, then moves the web forward in a single plane into a second plurality to dry the other side. The court concluded that "single tier" means single plane, and that unfolding Soininen's two rows into a single plane would not have been obvious.

Although the figures in Valmet's Soininen patent depict various stacked arrangements, nothing in the patent requires a stacked arrangement of the two rows of drying cylinders. On the contrary, the phrase "substantially parallel" explicitly encompasses parallel configurations in one plane or in two different planes. At the same time, nothing in Beloit's '758 or '372 patents requires an arrangement of the two pluralities of drying cylinders horizontally disposed in a single plane. Furthermore, Beloit's specifications and prosecution histories make it clear that the phrase "single tier" primarily serves to distinguish prior art "two tier" sections where the web traveled alternately around cylinders in two different tiers on two different planes. Thus, we hold that the district court incorrectly limited the teachings of Soininen, misconstrued Beloit's patents, and erroneously overstated the differences between the two inventions.

b) Meaning of the Term "Parallel Coplanar, Horizontally Disposed"

Claim 4 of the '317 patent is limited by the requirement that the hot air flow channels be "parallel coplanar, horizontally disposed," (R. 36, Exhibit 1, column 6, ll. 11-12), and claim 1 by the requirement that the channels be "substantially parallel coplanar, horizontally disposed." (Id. at ll. 36-37). These words are to be given their ordinary and customary meaning, unless the '317 patent specifically defines the terms. 8

8 See Vitronics, 90 F.3d at 1582 ("Although words in a claim are generally given their ordinary and customary meaning, a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history."

CP argues that the word "substantially" "provides a non-absolute connotation" to the terms "parallel," " coplanar," and "horizontally disposed" such that " coplanar" is "better defined as the greater majority of the surface area within the channels
are in the same plane" and that "horizontally disposed" "is better defined as being 'substantially … horizontally disposed.'" (R. 39, p. 4). CP neglects the fact that the term "substantially" appears only in claim 1. "Although different claims should be presumed to cover different inventions, 'if a claim will bear only one interpretation, similarity [with another claim] will have to be tolerated." Laitram Corp., 143 F.3d at 1463 (citations omitted). A review of the entire patent, including the specification, reveals that claims 1 and 4 describe the same invention and will bear only one interpretation. Thus the word "substantially," which appears only in claim 1 of the '317 patent does not broaden the scope of the patent as CP contends.

This interpretation is particularly supported by the meaning of the term "parallel." This term is used to describe the spacial relationship between the two "hot air flow channel" structures that comprise the "heating means" of the Satisfyer. The '317 patent specifically defines the term "parallel" to mean "in spaced apart parallel relation," (R. 36, Exhibit 1, column 1, ll. 65-66), or "in parallel spaced apart relation." (Id. at column 4, ll. 12-13). In addition, the artwork to which the written description of "parallel" refers clearly demonstrates the hot air flow channels being "parallel" and not "substantially parallel," See (Id. at Figures 2, 4 and 5). Further, the "Detailed Description" of the invention explains that each hot air flow channel is configured in a series of "right angle turn[s]." (Id. at column 4, l. 45). 9 "Right angle" is not defined within the '317 patent; therefore it must be given its ordinary and customary meaning. Vitrronics, 90 F.3d at 1582; Sage Products, Inc. v. Devon Industries, Inc., 126 F.3d 1420, 1423 (Fed. Cir. 1997). Webster's Collegiate Dictionary (10th ed. 1993) defines "right angle" as "the angle bounded by two lines perpendicular to each other; an angle of 90 [degrees] …” Because each hot air flow channel is configured in a series of such angles, it is impossible for them to be anything but "in parallel spaced apart relation." Finally, Figures 2, 4 and 5 of the specification depict the hot air flow channels as being "in parallel spaced apart relation." The word "substantially" does not expand the coverage of the term "parallel" as used in claim 1.

9 In fact, at several instances within the patent specification, the hot air flow channels are said to make "right" or "left" angle turns. See (R. 36, Exhibit 1, column 4, ll. 15-16, 18-29, 45).

The same can be said for the terms "coplanar" and "horizontally disposed." Unlike "parallel," neither of these claim terms are defined in the specification. Consequently, they must be given their ordinary meaning. Vitrronics, 90 F.3d at 1582; Sage Products, 126 F.3d at 1423. Webster's Collegiate Dictionary (10th ed. 1983) defines "coplanar" as "lying or acting in the same plane" and "horizontal" as "parallel to, in the plane of, or operating in a plane parallel to the horizon or to a base line." Figures 4 and 5 within the specification illustrate the "coplanar, horizontally disposed" configuration of the hot air channels. They confirm that each hot air flow channel lies within the same plane and is parallel to the horizon. 10 See (R. 36, Exhibit 1, Figures 4 & 5).

10 As with the Court's discussion of the term "parallel," Figures 2, 4 and 5 of the specification reveal that the "hot air flow channels" of the Satisfyer can only be arranged in the same plane and parallel to the horizon. Thus, the word "substantially" in claim 1 cannot be construed to broaden the definition of either "coplanar" or "horizontally disposed."

The prosecution history of the '317 patent lends further support to this interpretation of the terms "coplanar" and "horizontally disposed." "Arguments and amendments made during the prosecution of a patent application and other aspects of the prosecution history … must be examined to determine the meaning of terms in the claims." Southwall, 54 F.3d at 1576. Prudhomme filed his initial patent application on May 26, 1987. (R. 36, Exhibit 2, p. A1124). The application described the "heating means" as either "comprising a hot air flow channel in a non-straight line configuration," or "comprising a pair of parallel hot air flow channels in a modified 'S' configuration." (Id. at pp. A1139-40). The initial application did not include the terms "coplanar" and "horizontally disposed." (Id.). Prudhomme abandoned his initial application after it was twice rejected by the PTO. (Id. at pp. A1153-55, A1177-79). Following a meeting between Prudhomme's attorney and a PTO representative, see (Id. at p. A1182), Prudhomme filed a "continuation" application. (R. 36, Exhibit 3). The "Remarks" section of the second application explains: "This Streamline Continuation is being filed pursuant to Claim amendments which were reviewed on August 19, 1988, but which could not be entered after final. The
Claim amendments are being filed as a result of the interview and to overcome the art cited by the Examiner, namely the patent to Kells, Childs, and Keating.” (Id. at p. A1232) (emphasis added).

In his continuation application, Prudhomme added the limitation that the hot air flow channels described in his independent claims be “coplanar” and “horizontally disposed.” (Id. at A1228-30). As recognized by the "Remarks" to the application, these terms were added to distinguish Prudhomme's invention from prior patents. Specifically, the Childs patent describes a deep fryer with a heating means comprised of several "combustion chambers … arranged vertically." (R. 36, Exhibit 13, column 3, ll. 40-45) (emphasis added); see also (Id. at Figures 1 & 3). In addition, the "combustion chambers" of the Childs deep fryer are not "coplanar." 11 (Id. at Figure 1). This review of the Childs patent reveals that the terms "coplanar" and "horizontally disposed" distinguish Prudhomme's invention from Child's in that the heating means in Prudhomme's invention run horizontally 12 through the frying chamber and are situated in the same plane, while the heating means within Child's fryer are vertical and non-coplanar.

--- Footnotes ---

11 The Court reaches this conclusion by comparing the planes that run through the centerlines of each "combustion chamber" of the Childs deep fryer. Because the combustion chambers are arranged vertically, these planes are parallel and not "coplanar." In contrast, a single plane runs through the centerlines of each hot air flow channel of Prudhomme's Satisfryer, and thus the Satisfryer's hot air flow channels "lie … in the same plane." Webster's Collegiate Dictionary (10th ed. 1993).

12 That is, the hot air flow channels of the Satisfryer are parallel to the horizon, see supra pp. 14-15, rather than vertical to the horizon, as in Child's invention. (R. 36, Exhibit 13, Figure 1).

--- End Footnotes ---

(1) "Substantially Parallel Said Reflector"

Defendants object to the Special Master's recommended construction of "substantially parallel said reflector" appearing in claims one and thirty-seven of the '414 Patent. Originally, when construing these terms the Parties proposed similar interpretations. For instance, Plaintiff proposed "[t]he lamps are close enough to parallel or generally parallel to the reflector such that the uniformity of lighting as generally described in the patent is achieved." Defendants proposed that the "[t]he lamps largely, but not wholly, follow the contour of (i.e. parallel) the reflector." Even though these proposed constructions were not substantially different, the Special Master proposed a much different construction which appears to encompass both a "visual" and "textual" construction. For example, with respect to the "visual" definition, the Special Master concluded in pertinent part:

The appropriate interpretation of "substantially parallel" neither rests on concepts of geometry nor concepts of parallelism, nor the application of a rule to a scaled drawing. Instead, the "generally parallel" relationship between a linear compact fluorescent lamp and a curved reflector represents a visual relationship which is both defined in terms of what the language means as well as what is illustrated in the drawings. So, in the context of the present case the "substantially parallel relationship represents an "eyeball" definition rather than a textual definition."

Perhaps what is most troubling about this visual construction is that it does not appear to be a construction of the claim terms. In fact, if the Court were to adopt such a "visual" or "eyeball" definition, the construction would ultimately be left to the jury as a finding of fact rather than a determination of law made prior to the trial by the Court. Importantly, as noted above and by the Defendants, claim construction is a matter of law that is to be determined by the Court. Markman, 52 F.3d at 983-84. Based upon the Special Master's proposal the jury would have to identify certain points on Plaintiffs patented lighting apparatus and compare with certain points on the accused device. Such a possibility is not consistent with the purpose of the claim construction portion of this litigation.
Similar to the Special Master's "visual" or "eyeball" definition, the Special Master's textual definition of "substantially parallel said reflector" appears to run contrary to settled claim construction principles. Specifically, the textual definition recommends in pertinent part:

A compact fluorescent lamp (such as lamp 45 shown in Fig. 15 of the Tickner patent) is a linear or straight line device that defines one of the two lines to be compared to evaluate whether the compact fluorescent lamp is substantially parallel to the sliced reflector.

The curved exposed edge of the sliced reflector (as illustrated in Fig. 15) from the top of the slice to the bottom of the slice can be thought of as many short, straight reflector segments joined end to end.

If any one of those numerous straight reflector segments located anywhere between the top of (sic) the bottom of the reflector slice is "more or less" or "about" or "generally" parallel to the compact fluorescent lamp, then you may find that the compact fluorescent lamp is substantially parallel to the reflector.

(Report and Recommendation, p.15).

As argued by the Defendants, the Special Master's textual definition appears to change or broaden the scope claim. The Special Master takes the original claim language and broadens it to be "substantially parallel any one of those numerous straight reflector segments located anywhere between the top [or] the bottom of the reflector slice." As evidenced by the prosecution history of the '414 Patent, the Special Master's textual definition appears to run contrary to the inventor's intent. For instance, in response to an office action, regarding the relationship between the instant '414 Patent and the relevant prior art, the Schmidt and McNair patents, Mr. Tickner, in describing the relationship between the reflector and fluorescent lamps stated the "lamps extend outwardly at an angle along a line generally parallel to the surface of said reflector means."

(Defendants' Objections, Exhibit E, p.2). At no point does the prosecution history of the '414 Patent evidence some type of relationship where only a point on the reflector is parallel or generally parallel the fluorescent lamps. Thus, given the Special Master's apparent rejection or failure to consider the relevant prosecution history and the Special Master's proposal that may change the scope of the claim, the Court will not adopt the Special Master's proposed construction. Rather, given the Parties close proposals that appear generally to be in line with the intrinsic evidence regarding the construction of "substantially parallel said reflector" the Court, upon Defendants' recommendation, adopts Plaintiff's proposed construction. Thus, "substantially parallel said reflector" will be construed to mean "[t]he lamps are close enough to parallel or generally parallel to the reflector." 1

1 Notably, at the oral argument hearing on February 28, 2007, Plaintiff's counsel indicated that Plaintiff would not object to adopting Plaintiff's proposed version, but urged the Court to adopt the Special Master's proposal.

D. "substantially parallel to"

The court finds that the phrase "substantially parallel to" means "largely extending in the same direction as."

Claim 1 provides for a "mounting shaft having a central axis that is substantially parallel to said longitudinal axis." Plaintiff would construe "substantially parallel to" as "largely extending in the same direction." Defendant argues that Plaintiff's construction is too broad, that it would admit devices not aligned well enough to position a sighting device with the necessary precision. Defendant therefore proposes "extending in the same direction as the longitudinal axis of the mounting base to a degree sufficient to permit a scope mounted to the firearm by means of the pivoting scope mount to maintain and return to zero."

- 4595 -
Defendant's proposed language would require all embodiments of the '152 Patent to be capable of mounting a precision scope. However, Claim 1 merely describes a clamping device; it does not specify the degree of precision with which a mounted accessory should function when attached to that device. Defendant's proposed language is therefore rejected as inappropriately limiting, and the court will adopt Plaintiff's proposed construction.

b. Element 1

"An outer shell of substantially parallelepiped shaped …"

The parties have stipulated that a parallelepiped shape is a polyhedron, all of whose faces are a parallelograms. (McGraw Hill Dictionary of Scientific and Technical Terms.) In this context, a parallelepiped structure would be a six-sided box where each opposing pair of sides are parallel. The parties disagree as to the meaning of the word "substantially".

The Plaintiff contends that the term "substantially" has the meaning that those skilled in the art already know or could ascertain with the use of a dictionary. Thus, the Plaintiff contends that the word "substantially" means "considerable in extent" or "largely, but not wholly that which is specified." York Products Inc. v. Central Tractor Farm & Family Cntr, Inc., 99 F.3d 1568 (Fed. Cir. 1995) (from American Heritage Dictionary, Second College Edition, 2d Edition 1982 and Webster's Ninth New Collegiate Dictionary, Ninth Edition, 1983, respectively). The Plaintiff explains that "substantially parallelepiped" therefore means a shape that is almost, but not quite a parallelogram. The Defendants argue that the phrase "substantially parallelepiped" is ambiguous and therefore must be limited by Figures 6 and 7 of the Specification.

The difficulty in giving meaning to the phrase "substantially parallelepiped" is not in the meaning of the word "substantially". It is, instead, that the word "substantially" negates the characterization of "parallelepiped" to some degree. The issue is in what way and to what degree a "substantially parallelepiped" shape differs from a parallelogram. Simply stated, an object that is "substantially parallelepiped" is an object which is not a parallelogram because not all of its opposing sides are parallel with each other. This meaning is clear, but describing a structure as "substantially parallelepiped" does not reveal which sides of the parallelogram are and are not parallel. To that extent, the phrase is ambiguous.

Where claim language is ambiguous and therefore cannot be understood, it is appropriate to refer to the written description in the Specification. Bell Atlantic Network Svs., 262 F.3d at 1270-71. Reference to the Specification is helpful in this context because it clarifies which sides of the module are not parallel. Figures 2, 3, 6 and 7 reveal that it is the end panels of each module that are not parallel to each other.

Modules of a size that may be manually processed are abutted together end to end in registration and welded together along two weld lines to form walls for the detention structure. The ends are indented so that the two weld lines at the wall section surfaces are the sole lines of registered contact. Exhibit 1, column 2, Ins 5-10. As best seen from Fig. 3, the module ends are not perpendicular to the front and back panel facings 11 and 12. Thus the apex 49 of the right angle triangular panel section 21 is displaced inwardly toward the center of the module .... The end plate 40 thus is at an angle 48 of a few degrees. As a result there is only line contact between adjacent modules along the apex 25 and the apex 50 when the modules are assembled in registration.
Thus, the Court concludes that for purposes of Claim 1, the phrase "substantially parallelepiped" means a six-sided parallelogram in which the end panels are neither parallel to each other nor perpendicular to the face walls.

a. Scope of Plaintiff's claim 3

Defendant argues that the scope of Plaintiff's claim does not encompass its socket because the angle of the terminal ends in its lamp socket is 120 degrees, and "120 degrees is not very close to perpendicular or 90 degrees at all." [Response, p. 10]. Defendant relies on Amhil Enters. v. Wawa, Inc., 81 F.3d 1554 (Fed. Cir. 1996), where the court held the phrase "substantially vertical" to pertain to items that deviated only slightly, if at all, from the vertical.

In Amhil, the patentee used the phrase "substantially vertical" interchangeably with "vertical" in both the specification, and within the claim. The court also noted that the patentee also used the language interchangeably during patent prosecution. Further, the court noted that based on prior art, if the claim was not construed as nearly vertical, the patent would be invalid for obviousness. Id. at 1560. Accordingly, the court held that "substantially vertical" meant "deviate only slightly, if at all, from the vertical…any other construction of claim 1 would render it invalid." Id. at 1562.

In Playtex Products, Inc. v. Procter & Gamble Company, 400 F.3d 901 (Fed. Cir. 2005), the court held that the phrase "substantially flattened surfaces" did not refer only to a flat surface, but could include curved surfaces, depending on the comparative reference point. The court noted that "the term substantial is a meaningful modifier implying approximate rather than perfect." Id. at 907. The court reiterated the holdings in recent cases involving interpretation of terms of degree. See Cordis Corporation v. Medtronic AVE, Inc., 339 F.3d 1352, 1361 (Fed. Cir. 2003) (refusing to impose a precise numeric constraint on the term "substantially uniform thickness" instead construing it to mean "of largely or approximately uniform thickness"); and, Anchor Wall Systems v. Rockwood Retaining Walls, Inc., 340 F.3d 1298 (Fed. Cir. 2003) (holding that the phrase "generally parallel" envisions some amount of deviation from exactly parallel and that such words of approximation, such as "generally," and "substantially," are descriptive terms commonly used in patent claims to avoid a strict numerical boundary to the specified parameter).

Here, Plaintiff gives two preferred embodiments in the specification. In the first embodiment, it states that "the blade axis is preferably at about a right angle from the cradle axis…the terminal is thus a one-piece right angle terminal…alternatively, the cradle axis can be at an obtuse angle 1 relative to the blade axis…" [Motion, Exhibit A]. In the second embodiment, Plaintiff discloses that "similar to the first embodiment, the terminals have a cradle axis and a blade axis that are substantially perpendicular…" Id. Plaintiff uses the phrase "at about a right angle" interchangeably with "substantially perpendicular." It does not use the word perpendicular interchangeably with any other phrase. Accordingly, the Amhil, supra, holding is not read by this Court as limiting the phrase "substantially perpendicular" to mean perpendicular.

--- Footnotes ---

1 An obtuse angle is an angle greater than 90 degrees, but less than 180 degrees.

--- End Footnotes ---

The explicit language of claim 3, "lead receiving end having an axis that is substantially perpendicular to an axis of said lamp receiving end," clearly envisions something more than strictly perpendicular; otherwise, the word "substantially" would have no meaning.

"Generally, there is a 'heavy presumption' in favor of the ordinary meaning of claim language as understood by one of ordinary skill in the art. ' Bell Atlantic Network Services, Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1268 (Fed. Cir. 2001) (citation omitted). But, the presumption in favor of the ordinary meaning can be overcome where the patentee chose to be his own lexicographer, by using terms in a manner other than their ordinary meaning. Id. "The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by
implication." Id.

Based on the language in the specification, the Court finds that Plaintiff intended to limit the phrase "substantially perpendicular" to "about a right angle," or 90 degrees. This is further evidenced by Plaintiff's characterization of its socket as a "right angle terminal."

The Court finds as a matter of law, based on the intrinsic evidence, that the phrase "substantially perpendicular" as used in claim 3, means an angle that is 90 degrees or approximately 90 degrees.

JVI proposes the following construction of this phrase: "each embedded leg is positioned in a plane sufficiently perpendicular to the faceplate and parallel to the longitudinal axis of the faceplate to permit significant flexing under vertical shear and tension forces." Universal proposes, "the terms 'substantially perpendicular' and 'substantially parallel' mean that the legs need not be exactly perpendicular and parallel; a slight degree of leeway is allowed. These terms are not defined in terms of serving a function, i.e., permitting significant flexing under vertical and shear tension forces."

The parties agree that "substantially perpendicular" and "substantially parallel" do not require the legs to be exactly perpendicular and parallel. The parties disagree, however, as to how much leeway is permitted. JVI argues that the amount of leeway permitted is enough to permit significant flexing under vertical shear and tension forces.

Universal disagrees with JVI's definition to the extent that JVI defines the phrase in terms of a function. Universal argues that the functional language of Claim 1 is directed at the flattening bends not the legs. It contends that the bends are angled to meet two functions: (1) to enable the embedded legs to be positioned in a plane; and (2) to allow said flange connector to flex under shear and tension forces. It is the angling of the flattening bend that allows for the flexing of the flange connector, not the perpendicularity or parallel relationship of the embedded legs. Universal argues that throughout the specification, the inventor describes the flexing functionality as related to the flattening bends.

The summary of the invention states that "the principal object of the present invention is to provide a flange connector that absorbs the shear force occurring in both the upward and downward directions and allow the flange connector to flex such that any failure in the connection is a ductile failure that can detected through an inspection of the joint." '897 Patent, Col. 2, 11. 41-48. The summary of the invention goes on to describe the design of the present invention that is used to "[t]o achieve these objectives . . ." '897 Patent, Col. 2, 11. 55-; Col. 3, 11. 10. Contrary to Universal's assertion, the functional language is not limited to the design of the flattening bends, but includes the design of the embedded legs. Thus, the Court accepts JVI's interpretation of this phrase.

Hynix argues that the phrase "substantially perpendicular" is indefinite because "it is unclear what degree of taper, if any, may be present" in the side walls of the embedded insulators. Hynix Br at 24. In particular, Hynix argues this phrase embraces only the minor, one or two degree variations in perpendicularity incidentally formed by the reactive ion etching process.
(RIE) techniques used in this invention. According to Hynix, "substantially perpendicular" cannot encompass deliberate attempts to taper the side walls of the embedded insulators through "RIE techniques under taper etching conditions."

But Hynix's arguments ring hollow. First, Hynix's contentions regarding "RIE techniques under taper etching conditions" have no bearing on the degree of taper in the side walls of the embedded insulators. The patent discusses this fabrication technique only once with respect to creating tapered side walls for the etch masks, not the embedded isolators. '715 patent at 25:9-12, FIG 37.

More importantly, the specification depicts numerous embodiments in which the side walls of the embedded insulator are slanted by more than one or two degrees. See '715 patent FIGS 15A, 15B, 18, 19, 20A, 20B, 21, 22, 23A, 23B, 24A, 24B, 25A, 25B, 29, 30, 31, 32, 33, 35, 36, 37, 38, 40. Indeed, the court's measurements of the embodiments in these figures indicate that these side walls deviate by at least seven (7) degrees. Hynix's construction would exclude these embodiments and is therefore disfavored. See C R Bard, 388 F3d at 865 ("[A] construction that excludes a preferred embodiment 'is rarely, if ever, correct.'").

Although the patent does not provide a numerical limitation for the term "substantially," the disclosed embodiments and the ordinary and plain meaning of "substantially" should be sufficient to guide a jury in performing its duties. If necessary, and if the parties marshal any new intrinsic evidence, the court would consider revisiting this issue at a later date. But for present purposes, the court rejects Hynix's construction and declines to construe this term.

Claim 6:
1. "wherein the spring is a substantially planar bent wire spring"

Plaintiff proposes the construction of "a spring having one or more bends in the same plane, thereby providing a substantially planar bent wire spring. It is not required that the spring be formed of a flat wire, but rather, that the shape of the spring be substantially flat or planar."

Defendant proposes the construction of "wherein the spring is a substantially flat bent wire spring."

The language of the term establishes that "bent wire" modifies "spring," indicating that the spring is composed of wire that is bent. The specification also supports this interpretation, stating that the spring or bias element may include a simple bend of 90 or 120 degrees, or a coiled bend of 360 degrees or greater. 476 Patent, Col. 4, lines 5-13. There is no limitation in the patent that the wire itself be flat. The specification notes that the preferred element is music wire, which is a round wire. 476 Patent, Col. 4, lines 14-15.

The court concludes that the proper construction is "a spring having one or more bends in the same plane, thereby providing a substantially flat shape. The spring may be composed wire that is not flat."

B. Claim Element 7(a): "a substantially planar cover portion conforming in shape to the opened end of said container"

The parties agree that this claim limitation describes the portion of the lid surrounding the spout. Playtex contends that the adjectives "substantially planar" should be construed to mean "substantially flat," rather than "substantially planar. " In response, plaintiffs argue that the term "planar" requires no further construction and, alternatively, that if the court defines the term planar, it should be construed to mean "thin in comparison to length and width."

The ordinary meaning of planar is "of or relating to a plane; lying in one plane . . . having a flat two-dimensional quality." Webster's, supra, at 1730. The relevant definition of "plane," in turn, is "a surface such that the straight line that joins any two of its points lies wholly in that surface: a two-dimensional extent of zero curvature: a surface any intersection of which by a like surface is a straight line." Id. The written description is not illuminating. The only reference to the substantially planar cover portion merely states that "the closure 10 is circular in shape, having a substantially planar cover portion and may vary in size depending upon the size of the beverage container 11."

The drawings reflect that the portion of the lid surrounding the spout is essentially flat and corresponds in shape to the beverage container.
Ultimately, the court believes that the parties have focused too narrowly on the term "planar." "Planar" does not stand alone in claim element 7(a). Rather, claim element 7(a) refers to "a substantially planar cover portion conforming in shape to the opened end of said container." (Emphasis added.) The meaning of the term "plane" can fairly be characterized as a flat, two-dimensional surface. But the meaning of this term is tempered by transformation of the root word "plane" into its adjective form, planar, which the court construes, according to its ordinary meaning, to mean having a flat, two-dimensional quality.

3 Plaintiffs argue the two-dimensional dictionary definition applies only to surfaces or other two-dimensional structures, not three-dimensional structures like lids and membranes. The dictionary, however, does not state that a planar structure is perfectly flat and two-dimensional. The dictionary uses the term "surface" and "two-dimensional" in defining "plane," but it defines "planar" as "of or relating to a plane . . . having a flat two-dimensional quality." Thus, by definition, a "planar" structure need not be perfectly two-dimensional. Rather, it must simply relate to or have a two-dimensional quality about it.

The patent further modifies the term "planar" with the adverb "substantially." "Substantially" is defined as "in a substantial manner: so as to be substantial." Webster's, supra, at 2280. "Substantial," in turn, is defined as "consisting of, relating to, sharing the nature of, or constituting substance: existing as or in substance." Id. And "substance" is defined as "essential nature . . . a fundamental part, quality, or aspect: essential quality or import: the characteristic and essential part." Id. at 2279. It is somewhat difficult to draw an ordinary meaning from these definitions because the definition of the adverb "substantially" is two steps away from the definition of the root word "substance." The thesaurus lists the following synonyms for the adverb "substantially": palpably, materially, structurally, largely, thick, in truth, in essence, and on the whole. Bartlett's Roget's Thesaurus 1321 (1996). The common thread between the dictionary definition and the synonyms listed in the thesaurus is various derivatives of the word "essence" such as "essential" and "essentially." Thus, if the court were to construe the term "substantially," it would likely construe it to mean something such as "a manner that constitutes the essential nature," "essentially," or "in essence." Ultimately, these definitions are no more helpful than the term "substantially," and therefore the court finds that the term "substantially" requires no further construction.

The court further notes that the "substantially planar cover portion" is relevant to an understanding of other claim elements. Claim element 7(b) claims attachable means, which the court construes infra to be a friction fit between the lid and the beverage container. Claim element 7(c) claims an elongated passageway extending upwardly and outwardly from the "said cover portion," meaning the "substantially planar cover portion" claimed in element 7(a). Given the language of the entire claim which is consistent with the intrinsic record, then, the court construes the phrase "substantially planar cover portion" to mean a cover portion having a substantially flat, two-dimensional quality.
This relative motion creates concomitant variations in the light transmission from source to sensor and thus grossly distorts the measurement of light extinction. When this motion occurs, variances of light transmission are erroneous indicators of light extinction. These extinction errors ultimately cause corresponding errors in oxygen saturation measurement, all as a result of discontinuous contact and other causes of relative motion between the light source, the photo-sensor, and tissue.

(PX 7, col. 2, lines 54-66) (emphasis added). The claimed invention addresses the problem of motion artifact as follows:

A further object of this invention is to disclose a process for making the apparatus. In the assembly of this invention, the light source and the photosensor are mounted to substrates and are constructed of such small dimensions that both independently conform with a low aspect ratio to the flexible adhesive strip.

(PX 7, col. 6, lines 9-14) (emphasis added). Thus,

when the sensor is adhesively fastened, the effect of the light source and photo-sensor being integrated into the adhesive fastener is that they become, in effect, a part of the skin. The resulting device is resistant to accidental removal and avoids constriction of blood vessels both internal and external. Most importantly, the low mass of the sensor itself and its conformance to the skin prevents motion, localized force, and the resulting contact interruption among the light source, photo-sensor and flesh.

(PX 7, col. 4, lines 59-68) (emphasis added). In the more detailed description of the preferred embodiment of the invention, both the light-emitting diodes and the photo-sensitive portion of the sensor are given very small dimensions "which give the apparatus low profile and aspect ratios." (PX 7, col. 9, lines 2-3) Moreover, once the photo-active elements are attached to their respective substrates, they are "captured " between two "opaque vinyl strips," one of which is apertured, thus "conforming the thickness of the photo-active substrates to the overall thickness of the flexible adhesive strip to which attachment occurs. The photo-active substrates as thus captured are ideally indistinguishable in the tactile sense from the flexible adhesive strip itself." (PX 7, col. 9, lines 41-45)

Mr. Corenman, one of the inventors and a qualified expert, explained that "substantially planar" means "mostly flat. In other words, a relatively flat shape for the initial shape of the structure. … No significant bumps." (D.I. 122 at 1065-66)

Given the problem addressed by the invention and the specification language describing the inventors' solution to the problem, the court finds the phrase "substantially planar … support structure" to mean a structure having substantially flat or flush surfaces.

b. "blood is substantially prevented from entering the proximal portion of the guide wire lumen"

The plaintiff proposes "blood from outside the catheter is substantially prevented from traveling through the distal portion of the guide wire tube into the proximal portion of the guide wire tube." The defendant proposes "to prevent nearly all of the blood from entering the proximal portion." The are two main disputes between the parties.

The first dispute is whether blood is substantially prevented from entering the proximal portion of the guide wire lumen, regardless of how the blood entered the guide wire lumen, or if only the blood that enters through the distal portion of the guide wire lumen is substantially prevented from entering the proximal portion. The plaintiff argues that this feature of the invention refers to the decrease in the diameter of the distal portion of the guide wire lumen and, therefore, the limitation only prevents blood from the distal portion of the guide wire lumen from entering the proximal portion. '358 patent, 2:45-50. In response, the defendant argues that the claim language nor the specification limits the term based upon where the blood originally enters guide wire lumen.

The second dispute is over the use of "nearly all" in the defendant's proposed construction. The plaintiff argues that
"substantially" may be understood according to its plain and ordinary meaning, and that "nearly all" would be inconsistent with the disclosed embodiment which recognizes that some blood will enter the proximal portion of the guide wire lumen. The defendant, on the other hand, argues that "nearly all" is supported in the prosecution history because the applicant, in distinguishing prior art, states that the guide wire lumen was "sized to prevent blood from entering the proximal portion of the guide wire lumen . . . ." Amendment, Feb. 8, 1999, at 4. The defendant also points to the inventor's notebook, which was used to demonstrate an earlier date of invention, stating that "the tip prevents blood flowing into the guide wire lumen" while acknowledging that "a small portion of blood will enter the guide wire lumen . . . ." Declaration, Jan. 10, 2000. Finally, the defendant supports its proposed construction based on the dictionary definition and how "substantially" has been defined in previous cases. See, e.g., LNP Engineering Plastics, Inc. v. Miller Waste Mills, Inc., 275 F.3d 1347, 1354 (Fed. Cir. 2002) ("substantially" means "largely, but not necessarily wholly"); Ecolab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1366-69 (Fed. Cir. 2001) ("substantially" means "largely, but not wholly"); York Products, Inc. v. Central Tractor Farm & Family Center, 99 F.3d 1568, 1572 (Fed. Cir. 1996) ("substantially the entire" means "nearly the entire"); Chemical Separation Technology, Inc. v. United States, 51 Fed. Cl. 771, 790 (Fed. Cl. 2002) ("substantially" means "nearly").

The Court agrees with the defendant that the patent does not limit the term based on where the blood enters the guide wire lumen. The Court, however, agrees with the plaintiff that "substantially" can be understood according to its plain and ordinary meaning. The cases cited by the defendant in support of its proposed construction are distinguishable. In the context of the patents involved in those cases, it was necessary for the courts to define "substantially." See LNP Engineering Plastics, 275 F.3d at 1354 (the term"substantially completely wetted" required construction in order to specify proper composition); Ecolab, 264 F.3d at 1366-69 (the term "substantially uniform" required construction in order to clarify the uniformity of the material); York Products, 99 F.3d at 1572-73 (the term "substantially the entire height thereof" required construction indicating how high ridges must cover a side wall). The term "substantially" as used in the '358 patent and the '057 patent does not have a technical meaning nor does it require construction beyond its plain and ordinary meaning.

5. "blood is substantially prevented from entering the proximal portion of the guide wire lumen"

The plaintiffs propose "blood from outside the catheter is substantially prevented from traveling through the distal portion of the guide wire tube into the proximal portion of the guide wire tube." The defendants do not offer any construction with respect to this term.

The plaintiffs request that the court revisit its decision in the Cordis case not to construe this term. No new arguments are presented in support. Rather, the plaintiffs reiterate that the "claims, specification, and logic do not suggest any correlation between the reduced diameter tip and any flow of blood into the catheter through the side or exit port." Plaintiffs' Opening Brief at 12. The defendants' response is silent.

After carefully considering the arguments raised, the court is not persuaded to alter its construction from the Cordis case. Accordingly, the Court concludes that this term does not requires construction.

B. "Substantially quadrilaterally shaped"

Plaintiff argues that the claim language "the enclosure along its major longitudinal axis being substantially quadrilaterally shaped" requires only that the sides of the pad cover "have an approximate four-sided shape - not necessarily a perfect four-sided shape - and/or a sum of internal angles of about 360 degrees." Plaintiff's Opening Claim Construction Brief at 10. Defendant argues that the term "substantially" allows some deviation from an exact mathematical quadrilateral, but cannot eliminate the requirement that the overall shape of the pad's sides still must be a quadrilateral.

The claim language, specification, and prosecution history do not make clear the meaning of "quadrilateral," and the Court will consult a dictionary and other extrinsic evidence to determine the term's ordinary and customary meaning.
"Quadrilateral" is defined as "a plane figure having four sides and four angles." Random House College Dictionary (1973). The parties note that basic principles of geometry hold that the sum of the interior angles of a quadrilateral must equal 360 degrees. See Exhibit E. Thus, if the sum of the interior angles of a polygon is not 360 degrees, the shape is not a quadrilateral. By definition, a quadrilateral has four planar sides, meaning that the sides are flat or level and are bounded by four straight lines.

Footnotes

1 A polygon is "a figure, esp. a closed plane figure, having three or more usually straight sides." Random House College Dictionary (1973). According to geometric principles, if the sum of the interior angles of a polygon is 180 degrees, the shape is a three-sided polygon (a triangle), which has three sides; if the sum of the interior angles is 360 degrees, the shape is a four-sided polygon (a quadrilateral); if the sum of the interior angles is 540 degrees, the shape is a five-sided polygon (a pentagon). See Exhibit E; Random House College Dictionary (1973).

For the reasons explained in the preceding section, the construction of claim terms relating to the pad structure's enclosure is with reference to the enclosure in a substantially filled state. The Court finds that the phrase "substantially quadrilaterally shaped" means that the enclosure along its major longitudinal axis has an overall quadrilateral shape with four sides which are overall flat or level and are composed of overall straight lines, and the shape's internal angles reach the sum of approximately 360 degrees.

Background

Akron filed the suit at bar against Excel in March 1992, seeking a declaratory judgment that its non-aerosol dispenser product does not infringe Claim 39 of the '829 patent. The '829 patent, entitled "Apparatus for Containing and Dispensing Fluids Under Pressure and Method of Manufacturing Same," is directed to a non-aerosol container assembly for dispensing fluids under pressure. Claim 39, with the language central to the infringement allegation emphasized, is as follows:

39. An apparatus for containing and dispensing a liquid under pressure comprising:

(a) a container housing having an opening at one end thereof;

(b) a flexible cylindrical container integrally formed of a blow molded generally homogeneous elastic plastic composition and having a central longitudinal axis, said blow molded container having a neck portion and a plurality of longitudinally extending creases disposed below said neck portion generally equidistantly from said central longitudinal axis, said blow molded container defining an inner region for containing the liquid under pressure and being folded inwardly along said creases only about said central longitudinal axis in its empty condition and expanded only in substantially radially outward directions when filled with the liquid under pressure, said blow molded container being substantially chemically and physically inert with respect to the liquid contained therein, said configuration and structure of said blow molded container being such that said blow molded container is expanded only in substantially radial directions when said blow molded container is filled with the liquid under pressure;

(c) a resilient generally tubular member positioned radially outwardly of said blow molded container, said resilient tubular member extending at least over the length of said blow molded container and being expandable in radial directions when said blow molded container is filled with the liquid under pressure, said resilient tubular member frictionally interacting with said blow molded container when said blow molded container is filled with the liquid under pressure such that said resilient tubular member and said flexible cylindrical container each expands generally uniformly only in directions substantially radially outwardly of said longitudinal axis along its length; and

(d) valve means connected solely to said neck portion and extending into said inner region no further than said neck portion of said blow molded container, said valve means further being secured to one end of said container housing at the
opening thereof when said blow molded container and resilient tubular member are assembled and positioned therein, said valve means being adapted to substantially prevent evacuation of said blow molded container under normal conditions and capable of selectively providing communication between said inner region of said blow molded container and the outside atmosphere thereby to permit selective amounts of said pressurized liquid to become dispersed and to exit said blow molded container due to the generally radially inward forces provided by said resilient tubular member in its generally expanded condition.

Exxel responded by filing an infringement counterclaim. Acting on the parties' cross-motions for summary judgment on the question of infringement, the district court concluded that Claim 39 reads on the Akron dispenser.

At the same time that it held in favor of Exxel on the question of infringement, the district court granted Akron's motion for leave to amend its complaint to include the allegation of unenforceability of the '829 patent due to inequitable conduct before the PTO. Specifically, Akron alleged that Exxel's predecessor-in-interest, Container Industries, Inc. ("Container"), the '829 patent's named assignee, intentionally failed to inform the examiner of the existence of a co-pending application, also assigned to Container, claiming quite similar subject matter. According to Akron, the co-pending application, though it was filed after the application that became the '829 patent, was prior art to the '829 patent and should have been disclosed during its co-pendency, and certainly no later than the date it issued as U.S. Patent No. 4,387,833 (the '833 patent).

The district court analyzed Akron's allegation of inequitable conduct in two ways. First, after noting that undisclosed information must be material to support a holding of inequitable conduct, the district court approached the question of materiality from the perspective of an interference proceeding, framing the central question as "whether the invention disclosed by [the] Venus [application 2] was patently distinct from that disclosed by [the] Katz [application 3]." After comparing two pairs of claims from the patents for purposes of illustration, the district court concluded that "the invention disclosed in the Venus '833 Patent was an improvement of the invention disclosed in the Katz '829 Patent . . . and therefore, there was no bar to the issuance of the Katz '829 Patent, and the Venus '833 Patent, although issued first, was not prior art to the Katz Patent." The district court then reframed the central question as "whether, at the time of the prosecutions, Attorney Catanzaro thought [the] Venus [application] was prior art to [the] Katz [application] and if so, whether he thought it was material and nonetheless chose not to disclose it to the Katz [application] examiner." Finding no evidence to suggest what "Catanzaro's thoughts were in this regard," the district court concluded that the reference was not material. The trial court also proceeded, despite what it viewed to be a lack of materiality, to conclude that there was also insufficient evidence of culpable intent to deem the patent unenforceable due to inequitable conduct.

--- Footnotes ---

2 The '833 patent derived from U.S. Patent Application No. 216,191, entitled "Apparatus for Containing and Dispensing Fluids Under Pressure and Method of Producing Same," naming Frank Venus as the inventor.

3 The '829 patent derived from U.S. Patent Application No. 182,155, naming Hyman Katz as the inventor.

--- End Footnotes ---

Finally, after finding that Akron's infringement of the '829 patent was not willful and noting that both parties' litigation conduct had been "troublesome" and "certainly annoying," the district court found that the case was not an "exceptional" one and thus denied Exxel's motion for attorney fees under 35 U.S.C. § 285.

Infringement

Patent infringement analysis involves two steps: the threshold construction of the meaning and scope of the asserted claim, followed by the determination whether the accused product infringes the properly construed claim. Markman v. Westview Instruments, Inc., 52 F.3d 967, 976, 34 U.S.P.Q.2D (BNA) 1321, 1326 (Fed. Cir. 1995) (in banc), petition for cert. filed, 64 U.S.L.W. 3068 (U.S. July 3, 1995) (No. 95-26). Where, as here, the parties do not dispute any relevant facts regarding the accused product but disagree only as to the proper construction of the asserted claim, the question of literal infringement collapses to one of claim construction, a question of law that we review de novo. Id. at 979, 34 U.S.P.Q.2D (BNA) at 1329.

Paragraph c of Claim 39 recites a "blow molded container" placed within a "resilient tubular member" such that, when the container is "filled with liquid under pressure," "each expands generally uniformly only in directions substantially radially
Akron moved for summary judgment of noninfringement on the ground that Claim 39, which, according to its construction, precludes all longitudinal expansion in the resilient tubular member, does not read on its dispenser, the resilient tubular member of which expands both radially outwardly and longitudinally. The district court rejected this construction of Claim 39 after reviewing the claim language, the specification, and the prosecution history, concluding that Claim 39 recites "an outer resilient rubber sleeve which is slid tightly over the plastic liner and which, upon inflation of the liner, expands mostly radially, but also minimally longitudinally."

Akron contends on appeal that the district court erred in so construing the claim, renewing its assertion that a construction that permits longitudinal expansion is "precluded by the prosecution history and the plain meaning of Claim 39 terms." We disagree. The language of the claim itself, far from precluding longitudinal expansion, recites "substantially radially outward[ ]" expansion—i.e., expansion that, while "substantially" radial, is not exclusively radial. In other words, the claim plainly accommodates a degree of longitudinal expansion. The specification supports this view. For example, in discussing the best mode for practicing the claimed invention, the specification indicates that "the expansion of the energy sleeve . . . is regulated . . . so as to expand substantially in a radial direction with negligible, if any, longitudinal variation." Finally, nothing in the prosecution history of the '829 patent is contraindicative: the prior art references cited by the examiner, and the amendments made in light of them, were directed to the longitudinal expansion of the blow molded container rather than of the resilient tubular member. Thus Katz did not, as Akron insists, disclaim all longitudinal expansion in the resilient tubular member in order to overcome the prior art rejections.

Akron raises a host of additional contentions, insisting, for example, that the judgment should be reversed in light of the court's purported comparison of the accused device with an embodiment produced by the patentee; all are unavailing. As we have often observed, with woefully little effect on the bar, "we review judgments, not opinions, and we need not close our eyes to the record where, as in this case, there is a way clearly open to affirm the trial court's action." Super Sack Mfg. v. Chase Packaging Corp., 57 F.3d 1054, 1057 n.2, 35 U.S.P.Q.2D (BNA) 1139, 1142 n.2 (Fed. Cir. 1995) (internal quotations and citation omitted).

Discerning no reversible error in either the district court's construction of Claim 39 or its application of the claim to the Akron dispenser, we affirm the judgment of infringement in Exxel's favor.

2. "said side walls curving downwardly and inwardly towards said conveyor means such that said dump body defines a substantially semi-elliptical cross-sectional configuration for guiding and evenly deflecting all of the materials within said body towards said conveyor means"

The clause "said side walls curving downwardly and inwardly towards said conveyor means such that said dump body defines a substantially semi-elliptical cross-sectional configuration for guiding and evenly deflecting all of the materials within said body towards said conveyor means" is nearly identical to the same language found in claim 1 of the '389 Patent. The only difference is that the instant clause refers to "a substantially semi-elliptical cross-sectional configuration" and claim 1 of the '389 Patent refers to "a substantially semi-circular cross-sectional configuration." Accordingly, HECO and Cives and Monroe offer similar constructions to the constructions that the court has already discussed in Part V. A.3 of the instant Order. The only difference is that HECO urges the court to construe "semi-elliptical" as "one-half of a geometric shape where the sum of the distance of each point on the curve from two fixed points remains constant." JCCC at 12-13.

The court construes this claim consistently with its construction of the nearly identical clause in claim 1 of the '389 Patent. The court notes that Figure 6 of the '786 Patent, like Figure 4 of the '389 Patent, contains a straight, non-curved portion at the top of the bin walls. Accordingly, the court construes the instant clause as follows:

This claim element requires that the side walls are curved, and that they curve downwardly and inwardly toward the conveyor of the dump body. The requirement that the "dump body defines a substantially semi-elliptical cross-sectional configuration" means that the dump body, viewed from either end, is approximately in the shape of a semi-ellipse.

"Substantially" is used to mean "approximately." Thus, the cross section of the dump body must be approximately in the shape of a semi-ellipse.
"Deflect," in its ordinary meaning, means to change course.

Id. The court also agrees that some construction of "substantially semi-elliptical" is warranted. It means "approximately a shape of a semi-ellipse, i.e., one half of a geometric shape where the sum of the distance of each point of the curve from two points remains constant."

3944

3. Substantially Similar

The modification of the claim term "counterbalanced weights" with "substantially similar" also betrays the Momentus interpretation of "counterbalanced weights" as being equal. "Substantially similar" certainly allows for some difference between the weights. On the other hand, it would certainly seem that this modifier does constrain the claim in that the weights cannot differ too much. Thus, the Court is left to shed light on the question of how similar is substantially similar. Momentus offers that "similar" is typically defined as likeness or resemblance or having the same shape. It seems reasonable to this Court that the modifier "substantially similar" would require the weights to have shapes and sizes that are alike, but not necessarily identical. In particular, if the weights are not equal, they may, by necessity, be different sizes. In that instance, the weights could still be "similar" in the geometric sense of the term by sharing the same shape.

3945

2. Three-dimensional Isodose Profile

Claim 1 of the '204 patent requires a "radiation source disposed in the inner spatial volume and generating a three-dimensional isodose profile that is substantially similar in shape to the expandable surface element." Claim 17 of the '204 patent recites "[t]he apparatus of claim 1, wherein the radiation source is a plurality of solid radiation sources arranged to provide an isodose profile having a shape substantially similar to the shape of the outer spatial volume." The parties propose the following constructions:

*   *   *

SenoRx seeks a construction requiring that: (1) the isodose profile referred to must be the final isodose profile delivered to the tissue; and (2) the isodose profile must be substantially the same shape as, and concentric with, the outer surface.

According to SenoRx the "absorbed dose" is the final, total dose resulting from the delivery of radiation and absorbed by the tissue at the end of radiation therapy. SenoRx states that the focus of the invention is on achieving a "predetermined dose range" in the target tissue, defined as the dose "between a minimum prescribed absorbed dose for delivering therapeutic effects to tissue that may include cancer cells, and a maximum prescribed absorbed dose above which healthy tissue necrosis may result." '204 patent 2:46-55. Thus, according to SenoRx, the "isodose profile" must be the final, cumulative dose.

Hologic disagrees, arguing that SenoRx is mischaracterizing the purpose of the invention in order to improperly limit the claim. According to Hologic, the '204 patent describes two primary purposes of the invention: to provide a uniform radiation dose to the targeted tissue and to ensure a predetermined dose range so that only cancerous tissue is destroyed by the radiation. Neither of these purposes requires that the isodose profile refer to the accumulated final dose. Indeed, as Hologic contends, one skilled in the art would understand and expect that the desired therapeutic result may call for the dose profile to be modified or adjusted. The Court agrees with Hologic that as used here, it is not appropriate to interpret the isodose profile as limited to a final, cumulative absorbed dose.

SenoRx also contends that the claim language requiring that the isodose profile be substantially the same shape as the outer expandable surface requires that the two be concentric. SenoRx points out that the specification describes the dose profile as
"within the target tissue at points equidistant from the surface of the outer spatial volume should be substantially uniform in substantially every direction." '204 Patent 5:13-19. Further, in distinguishing the '204 patent over the prior art, the applicants stated that the prior art did not have balloons that were equally spaced apart and therefore could not create an isodose profile that had substantially the same shape as the outer element. See Ex. 9, Dec. 20, 2000 Am., '204 Prosecution History. The prior art showed a figure that had two balloons but the inner balloon was positioned off center from the outer balloon.

Hologic contends that the specification language and prior art distinction do not require that the expandable surface be concentric with the isodose profile. It is possible, Hologic argues, to have an isodose profile that is substantially similar in shape as, but not concentric with, the expandable surface. Hologic suggests that a single radiation source enclosed in an expandable spherical outer surface and distributed off center but on the longitudinal axis would have a such a dose profile. This arrangement is shown in Hologic’s claim construction presentation diagram below:

The dotted line in the above diagram is meant to represent the shape of the isodose profile. But the isodose profile refers to levels of equal dose delivered to tissue, and in the above diagram the radiation would be subject to the attenuating material in different degrees. Because the source is positioned off center, the radiation at the distal end would be attenuated less than that at the proximal end. In the above diagram, the dotted line on the right of the diagram would be closer to the wall of the inner chamber. Hologic's diagram is thus not an example of a similarly shaped but non-concentric isodose profile. Indeed, any isodose profile that is non-concentric with the expandable surface would be asymmetrically attenuated in the same way. Thus, the requirement that the isodose profile be the same shape as the expandable outer surface also requires that the two be concentric.

Accordingly, the Court finds construes the term "three-dimensional isodose profile that is substantially similar in shape to the expandable surface element" to mean "three-dimensional isodose profile that is substantially the same shape as the outer spatial volume expandable surface and is concentric with the outer spatial volume expandable surface."

4. "Said deforming step substantially simultaneously applying uniform inward radial pressure on said mat." Consistent with the claim language and its ordinary meaning, the court construes "said deforming step substantially simultaneously applying uniform inward radial pressure on said mat" to mean "unvarying inward radial pressure is applied to the mat at essentially the same time the tubular body is deformed."

8 Random House Dictionary of the English Language 1784, 1897 (2d ed. 1987) (defining "simultaneous" as "existing, occurring, or operating at the same time; concurrent" and defining "substantial" as "basic or essential; fundamental" and "of or pertaining to the essence of a thing; essential, material, or important"); D.I. 151, ex. E at 1290 (defining "uniform" as "having always the same form, manner, or degree: not varying or variable").

9 '264 patent, col. 2, ll. 34-42; col. 3, ll. 2-5, 58-61.
engaging fastener can be pivoted within said recess portion of said at least one hole so that said first bone engaging fastener can assume a plurality of angles relative to said bottom surface of said plate.

The parties dispute the proper construction of the phrase "substantially smaller."

The specification does not contain a definition of "substantially," "smaller," or "substantially smaller" requiring departure from the ordinary meaning of the phrase. The parties have not pointed the Court to any representations made during prosecution that would limit the claim beyond its ordinary meaning. The Court construes "substantially smaller" to mean a considerable degree of difference between the relative diameters.

There is no basis for imputing a numerical limitation into the claim, as Plaintiff proposes. "[T]he term substantially' is a descriptive term commonly used in patent claims to avoid a strict numerical boundary to the specified parameter." Ecolab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1367 (Fed. Cir. 2001) (internal quotation omitted). See also Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1551 (Fed. Cir. 1996) ("Ordinarily a claim element that is claimed in general descriptive words, when a numerical range appears in the specification and in other claims, is not limited to the numbers in the specification or the other claims."); Epcon, 279 F.3d at 1030-31 (declining to attach specific values to construe the term "substantially below").

There also is no basis for construing the claim according to the purpose of the invention. "Nonnumerically limited descriptive claim terms are construed using the same rules of construction as any other claim term." Ecolab, 264 F.3d at 1366. The claim states "a third diameter that is substantially smaller than said second diameter." (Emphasis added.) This language relates "substantially smaller" to the third diameter, not to the function of the invention. See id. at 1366-67. Defining "substantially smaller" in terms of the function would not be proper.

"The mere use of a term like substantially' to modify a term in a claim does not render a claim indefinite. " Id. at 1020. To determine whether one skilled in the art would understand the claim, courts look to disclosures in the patent specification such as measurements and the purpose of the invention. See, e.g., Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1377-81 (Fed. Cir. 2001); Advanced Cardiovascular, 96 F. Supp. 2d at 1020.
Here, the 927 Patent discloses figure 19, showing the relative diameters of the intermediate portion of the variable bone engaging fasteners and the opening on the bottom surface of the plate. Although not accompanied by dimensions, the figure enables one skilled in the art to understand that the claimed invention enables the fasteners to move when they are inserted into the holes. This understanding is strengthened by the statement in claim 1 that the head of the fastener "can be pivoted" within the recess portion of the hole "so that said first bone engaging fastener can assume a plurality of angles relative to said bottom surface of said plate." The specification and purpose of the claimed invention show the claim limitation "substantially smaller" is not invalid for indefiniteness.

GO BACK

3948

The anticipation of Claims 1 and 2 rests on whether the '769 patent discloses a side wall that is "substantially smooth but for an internal annular projection." The '769 patent shows a vessel side wall that contains an internal annular shoulder projecting inwardly from a position near the top of the vessel side wall. Above the internal annular shoulder is a thickened area that receives a fastening bolt. Morgan points to this thickened portion of the side wall as evidence that the side wall is not substantially smooth. The Board properly rejected Morgan's constricted definition of "substantially smooth." Claims subject to reexamination are to be given their broadest reasonable interpretation consistent with the specification. In re Yamanoto, 740 F.2d 1569, 1571 (Fed. Cir. 1984). The '271 specification does not define the claim element "substantially smooth," therefore the Board correctly gave the term its broadest reasonable construction by requiring a mostly, but not wholly, smooth side vessel wall. The vessel side wall disclosed by the '769 patent is primarily uniform, i.e., substantially smooth, even with the presence of the thickened portion at the top end of the side wall. The Board's finding of anticipation of Claims 1 and 2 of the '271 patent is thus supported by substantial evidence.

GO BACK

3949

The district court's grant of summary judgment of noninfringement as to claim 1 of the '143 patent was premised on the court's claim construction. On-Line contends that the district court erred in construing the claim and therefore erred in entering summary judgment.

Claim 1 of the '143 patent recites as follows (emphasis added):

A folded-path radiation absorption gas cell comprising: an enclosure having first and second ends, and defining a substantially closed chamber therewithin; spaced input radiation and output radiation windows formed through said first end of said enclosure and aligned on a first axis; a concave reflective field surface extending at least partially between said windows at said first end of said enclosure; a pair of substantially spherical, concave reflective objective surfaces at said second end of said enclosure disposed in confronting relationship to said field surface, said objective surfaces being aligned side-by-side on an axis parallel to said first axis and in optical registry with said windows, at least one of said objective surfaces having a cylindrical component added thereto to increase coincidence of foci in two orthogonal planes, thereby to maximize the energy throughput characteristic of said cell; and means for the introduction and withdrawal of gas into and from said chamber of said enclosure.

The invention to which claim 1 is directed is an improvement on a type of gas cell known as a "White cell." A White cell uses several mirrors that are aligned to make the light follow a long path as it passes through the test chamber. In the invention, two mirrors are placed side by side at the opposite end of the main chamber from a third mirror. A beam of light enters the chamber and is repeatedly reflected off the three mirrors until it reaches an exit point. Because the mirrors reflect the light beam back and forth across the chamber multiple times, the path of the beam is much longer than the distance from one end of the chamber to the other.

The '143 patent sought to address the problem of astigmatic diffusion of the light beam passing through the cell. The solution proposed by the '143 patent was to shape the secondary mirrors in a manner that would counteract the astigmatism induced by reflections from the spherical mirrors used in White cells and thus keep the beam of light focused during its

- 4609 -
passage through the cell. ‘143 patent, col. 4, ll. 52-62. To achieve that purpose, each claim of the ‘143 patent required the mirrors to have "substantially spherical, concave reflective objective surfaces . . . at least one of said objective surfaces having a cylindrical component added thereto to increase coincidence of focii in two orthogonal planes . . . " Id., col. 5, ll. 44-52; col. 6, ll. 14-22, 40-48.

On-Line asserted that Perkin-Elmer's commercial long-path gas cells infringed claim 1 of the ‘143 patent. In particular, On-Line contended that Perkin-Elmer's cells used objective mirrors of the sort recited in the claim to correct for astigmatism. In the district court, Perkin-Elmer did not dispute that its accused gas cells used objective mirrors shaped to correct for astigmatism. Perkin-Elmer argued, however, that its objective mirrors had toroidal surfaces, not "substantially spherical" surfaces "having a cylindrical component added thereto," as required by claim 1 of the ‘143 patent. For that reason, Perkin-Elmer argued, its gas cells were not within the scope of the patent, either literally or under the doctrine of equivalents. In essence, Perkin-Elmer's argument was that a toroidal surface is different from a substantially spherical surface with a cylindrical component added to it. Because On-Line not only did not claim toroidal mirror surfaces but specifically omitted them from its claims, Perkin-Elmer contends that On-Line had dedicated surfaces of that shape to the public. The district court agreed with Perkin-Elmer and held that Perkin-Elmer's toroidal surface was not covered by the ‘143 patent.

In explaining its claim construction ruling, the district court noted that the specification described the contour of the spherical objective mirrors as "approaching toroidal." ‘143 patent, col. 4, ll. 8-12. The court stated that "because mirrors with a contour which only 'approaches toroidal' cannot be said to be actual toroidal mirrors, toroidal objective mirrors are not spherical objective mirrors with cylindrical corrections." In support of that conclusion, the court cited extrinsic evidence, including testimony from the inventors, which the court characterized as establishing that "spherical objective mirrors with cylindrical corrections are not the same as toroidal objective mirrors." Because the court concluded that the claim language excluded toroidal surfaces, the court held that Perkin-Elmer's gas cells did not literally infringe claim 1 of the ‘143 patent. Moreover, because the court concluded that toroidal surfaces were disclosed but not claimed in the ‘143 patent, the court invoked the principle that a patentee's disclosure of unclaimed subject matter bars application of the doctrine of equivalents to that subject matter and held that On-Line could not rely on the doctrine of equivalents to reach toroidal mirrors such as Perkin-Elmer's.

On appeal, On-Line contends that the district court erred in ruling that objective mirrors having a toroidal surface are not within the scope of claim 1 of the ‘143 patent. We agree with On-Line that, properly construed, the reference to a "substantially spherical, concave reflective surface . . . having a cylindrical component added thereto to increase coincidence of focii in two orthogonal planes" defines a set of curved surfaces that includes a toroidal surface. We reach that conclusion because the specification makes clear that the claim language referring to spherical surfaces with cylindrical components includes toroidal surfaces.

A toroidal (or toric) surface is defined as a surface that is "generated if an arc is rotated about an axis which lies in the same plane as the arc, but which does not pass through its centre of curvature." M. Jolie, The Principles of Ophthalmic Lenses 31 (3d ed. 1977). The classic example of a toroid is the shape generated when a circle is rotated about a line that does not intersect the circle, which describes a torus, a figure resembling a doughnut or tire. A toroidal surface is the shape of a segment of the surface of a toroid. Id.

Although the parties agree that the term "toroidal" has a well-understood definition, neither party suggests that the term "substantially spherical, concave reflective surface . . . having a cylindrical component added thereto," used in the claims of the ‘143 patent, has a precise and well-established meaning in the art. Rather, the evidence before the trial court indicates that the reference to spheres and cylinders is borrowed from thin lens theory, and that a lens characterized as spherical with a cylindrical component is one with an optical function achieved by "stacking" spherical and cylindrical lenses. The evidence shows that the same nomenclature is sometimes used, albeit with some lack of precision, to refer to reflective surfaces having similar optical properties to such stacked lenses, even though reflective surfaces cannot be stacked in the same manner as lenses.

Because the phrase "substantially spherical . . . having a cylindrical component added thereto" has no precise and generally understood meaning in the art as applied to reflective surfaces, we look to the intrinsic evidence, in this case the specification, for guidance as to the meaning of that language as used in the patent. See Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1324-25 (Fed. Cir. 2002) ("The words used in the claim are interpreted in light of the intrinsic evidence of record . . . . The intrinsic evidence may provide context and clarification about the meaning of claim terms.

- 4610 -
'Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language.' (citations omitted); Genentech, Inc. v. Wellcome Found. Ltd., 29 F.3d 1555, 1563 (Fed. Cir. 1994) ("Since a definition of [the critical claim] phrase cannot be extracted from the claims themselves, we look to the specification for guidance."); see also United States v. Adams, 383 U.S. 39, 49, 15 L. Ed. 2d 572, 86 S. Ct. 708, 174 Ct. Cl. 1293 (1966) ("Claims are to be construed in the light of the specifications and both are to be read with a view to ascertaining the invention.").

Although in this case, as in others, "the guidance [in the specification] is not provided in explicit definitional format," Irdeto Access, Inc. v. EchoStar Satellite Corp., 383 F.3d 1295, 2004 U.S. App. LEXIS 19235 at *12, No. 04-1154, slip op. at 8 (Fed. Cir. Sept. 14, 2004), the specification of the '143 patent nonetheless demonstrates that the claim language encompasses toroidal surfaces. First, the specification refers to the curved surfaces in the preferred embodiment of the invention as toroidal surfaces ("the toroids of the surfaces 62, 64," '143 patent, col. 4, line 16), and in doing so it describes those surfaces by using the same language that is used in claim 1 ("generally spherical reflective surfaces," each of which "has a cylindrical component superimposed thereupon," id., col. 4, ll. 7-10). Accordingly, the specification makes it clear that, for purposes of the '143 patent, a toroidal surface is a substantially spherical reflective surface that has a cylindrical component superimposed thereupon.

Second, even if the specification were less explicit in equating the term "toroid" with a generally spherical surface having a cylindrical component added thereto, the reference to the preferred embodiment as having mirrors with toroidal surfaces would give rise to a very strong inference that the claim should be construed to include such surfaces. As this court has explained before, "a claim interpretation that excludes a preferred embodiment from the scope of the claim 'is rarely, if ever, correct.'" Globetrotter Software, Inc. v. Elan Computer Group, Inc., 362 F.3d 1367, 1381 (Fed. Cir. 2004), quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996); see also Int'l Rectifier Corp. v. IXYS Corp., 361 F.3d 1363, 1371 (Fed. Cir. 2004); Modine Mfg. Co. v. U.S. Int'l Trade Comm'n, 75 F.3d 1545, 1550 (Fed. Cir. 1999).

The district court interpreted the reference in the specification to a "contour that approaches toroidal," '143 patent, col. 4, line 12, as indicating that the recited surface could include a surface that approximates a toroidal shape, but could not include the toroidal shape itself. We disagree with that interpretation. From the description of the mirror surfaces of the preferred embodiment in "toroids" four lines later in the specification, we think it clear that the words "approaching toroidal" were not meant to exclude curves designed to be toroidal in shape, but simply to indicate that the surfaces recited in the invention were intended to include all curves that closely approximate toroidal, including a toroidal surface itself. Indeed, as a matter of manufacturing tolerances, it is impossible to make a real-world device with a reflecting surface that is perfectly toroidal, just as it is impossible to make a reflecting surface that is a perfect spheroid or a perfect paraboloid. For that reason, even mirrors that are designed to be toroidal, such as the mirrors in Perkin-Elmer's device, will necessarily merely "approach" the ideal toroidal shape, although they may come very close. Accordingly, we do not agree with the district court that the reference in the specification to a surface that "approaches toroidal" was meant to exclude a device having a surface that is characterized in the art of optical engineering as "toroidal."

Finally, the patent describes the effect of adding a cylindrical component to a generally spherical mirror as being "to reduce the effective radius of curvature in one plane, thus enabling light incident on the reflective surface to better approach the focus in the orthogonal plane," '143 patent, col. 4, ll. 60-62, and "to increase coincidence of foci in two orthogonal planes," id., col. 5, ll. 51-52. A toroidal surface "has two principal radii of curvature corresponding to its two principal curves," M. Jolie, supra, at 31; see also Jurgen R. Meyer-Arendt, Introduction to Classical & Modern Optics 120 (3d ed. 1989) ("A toric surface has two radii of curvature (different in the two principal meridians"); Daniel Malacara, Optical Shop Testing 754 (2d ed. 1992). That characteristic makes toroidal surfaces useful in counteracting astigmatism. See Eugene Hecht, Optics 211-12 (3d ed. 1998). Thus, while the claim language in the '143 patent does not either expressly include a toroidal surface or exclude other similar surfaces, the characteristics and function of the surface described in the specification and the claims are consistent with the characteristics and function of a toroidal surface.

The district court relied on extrinsic evidence that the court interpreted as supporting its claim construction. Extrinsic evidence, however, cannot be used to alter a claim construction dictated by a proper analysis of the intrinsic evidence. See Intel Corp. v. VIA Techs., Inc., 319 F.3d 1357, 1367 (Fed. Cir. 2003) ("When an analysis of intrinsic evidence resolves any ambiguity in a disputed claim term, it is improper to rely on extrinsic evidence to contradict the meaning so ascertained."); Frank's Casing Crew & Rental Tools, Inc. v. PMR Techs., Ltd., 292 F.3d 1363, 1374 (Fed. Cir. 2002); Bell & Howell Document Mgmt. Prods. Co. v. Altek Sys., 132 F.3d 701, 706 (Fed. Cir. 1997). In any event, we do not agree with the district court's analysis of the extrinsic evidence.
Although the evidence showed, and On-Line's witnesses acknowledged, that the mathematical description of a toroid differs from that of a spherocylinder, On-Line offered evidence that a person of skill in fabricating optics would understand the expression "sphere with cylindrical correction" or a sphere "having a cylindrical component" to refer not to a mathematical concept but to the type of optical correction obtained by stacking thin lenses, one having a spherically curved surface and another having a cylindrically curved surface. According to On-Line's expert, a person of ordinary skill in the art would understand the term "sphere with cylindrical correction," as a way of describing the curved surfaces used in On-Line and Perkin-Elmer's commercial products, i.e., toroidal surfaces. The evidence in the summary judgment record therefore provides further support for On-Line's contention that the surface of the objective mirrors recited in claim 1 of the '143 patent includes toroidal surfaces, as that term is understood by persons of skill in the pertinent art, as opposed to the manner in which it is used by mathematicians.

To be sure, On-Line's inventors acknowledged that as a mathematical concept a toroidal surface is not the same thing as a spherical surface with a cylindrical component added to it. That is not to say, however, that the inventors regarded toroidal surfaces as falling outside the broader claim language, which referred to "substantially spherical" surfaces "having a cylindrical component added thereto." As On-Line's expert explained, "the sphere/cylinder convention does not specify the exact mathematical surface . . . . A person of ordinary skill in the art would understand the term 'sphere with cylindrical correction' as a terse and natural way to describe the modestly curved surfaces of the objective mirrors in On-Line's or Perkin-Elmer's gas cell [both of which are toroidal]." Moreover, while acknowledging that the mathematical definition of a toroid differs from that of a spherical cylinder, co-inventor Robert Carangelo testified that the claim language "substantially spherical . . . having a cylindrical component added" includes a toroidal surface. The other co-inventor, David Wright, testified to similar effect, stating that the claim language was intended to cover a range of conic sections, including ellipsoids and toroids, all of which would have the same shape near the axis "to within the order of machining tolerance."

Finally, even the technical article on which Perkin-Elmer relies to demonstrate that there is a mathematical distinction between toroidal and spherocylindrical surfaces points out that the distinction is extremely subtle for most applications and that toroidal surfaces "are sometimes also [referred to] as spherocylindrical surfaces." Carmen Menchaca & Daniel Malacara, Toroidal and Spherocylindrical Surfaces, 25 Applied Optics 3008 (1986).

Because of the lack of precision in the language used to define the claimed surfaces of the objective mirrors, this case was made more difficult than it needed to be, and the district court was required to invest considerable effort in trying to ascertain the meaning of the critical claim language. While the district court conducted a careful analysis of the claim language in light of the specification and the extrinsic evidence, we are nonetheless persuaded, particularly in light of the specification, that the district court's claim construction was too restrictive and that a surface designed to be toroidal is within the scope of claim 1 of the '143 patent. Accordingly, because the summary judgment of noninfringement was based on an erroneous claim construction, we vacate the judgment of noninfringement and remand the case for further proceedings on the remaining issues pertinent to On-Line's claim of infringement.

4. "Substantially Straight Compartments"

Finally, the Special Master observed that "[e]ach independent claim of the '668 Patent requires the formation of "substantially straight" cells or compartments." (R&R at 73.) This Court has construed the term "substantially straight" to mean "straight along nearly the entire length of the joint forming the compartment." (8/4/04 Order accepting and adopting Special Master's R&R, as supplemented by 7/15/04 R&R.)

The Special Master further observed that "[a]ll but one of the asserted claims of the '668 Patent employs the 'comprising' transition phrase. In accordance with fundamental patent law principles, each of the compartments of an accused airbag[] need not be 'substantially straight' in order to infringe claims of the '668 Patent. Rather, only 'at least two' of these compartments need be substantially straight." (R&R at 73, citing ResQNet.com, Inc. v. Lansa, Inc., 346 F.3d 1374, 1382 (Fed. Cir. 2003).) Considering TRW's and ATI's arguments and supporting evidence, as well as his own review of the images of inflated airbags, the Special Master concluded that "a genuine issue of material fact exists as to whether the accused airbags incorporate at least two 'substantially straight' compartments or not." (R&R at 74.) Drawing all inferences in favor of ATI, the Special Master concluded that "each of the inflated airbags appears to have an upper or lower
compartment, running parallel to the top or bottom of the vehicle door, that could fairly be described as rectangular in shape", and "[a] rectangular compartment is necessarily bounded by 'substantially straight' seams." (R&R at 74.) He further concluded that "each of the airbags incorporates at least one other compartment that, while not rectangular in shape, could arguably be described as defined by 'substantially straight' seams." (R&R at 74-75.) Finding a genuine issue of material fact exists on the issue whether the accused airbags include at least two "substantially straight" compartments, the Special Master recommended that TRW's motion for summary judgment of non-infringement based on the "substantially straight" limitation in claims 1-2, 4-6, 9-13, 15, 17-18, 20-33, and 35-44 be denied.

As to claim 45, which is the sole '668 Patent claim that incorporates the transition phrase "consisting of," the Special Master observed that the phrase "amounts to 'a term of patent convention meaning that the claimed invention contains only what is expressly set forth in the claim.'" (R&R at 75, quoting Norian Corp. v. Stryker Corp., 363 F.3d 1321, 1331 (Fed. Cir. 2004).) He further observed that TRW did not account for the implications of the use of that transition phrase in claim 45, and thus he had "no basis to determine the propriety of TRW's non-infringement argument beyond its assertions for those claims drafted using the open, 'comprising' phrase." (R&R at 75-76.) Accordingly, the Special Master recommended that TRW's motion for summary judgment of non-infringement based on the "substantially straight" limitation found in claim 45 be denied.

This Court accepts and adopts the Special Master's recommendation that TRW's motion for summary judgment of non-infringement be denied as to these claims and overrules TRW's objections. The Special Master properly concluded that only two of the compartments need to be substantially straight to satisfy this limitation. Moreover, viewing the one example provided by TRW, a reasonable jury could find two substantially straight chambers and thus find infringement either literally or equivalently.

8. "Substantially straight segments." Consistent with its ordinary meaning 20 and the written description, 21 the court construes "substantially straight segments" to mean "portions of the stent that are straight or nearly straight and extend the length of the stent.'

20 See American Heritage Dictionary 1213 (2d ed. 1984) (defining "substantial" to mean "considerable in importance, value, degree, amount or extent").

16. "Substantially straight, non-overlapping segments." Consistent with its ordinary meaning, 37 the court construes this phrase to mean "portions of a stent that are straight or nearly straight and do not extend over or cover part of any other segment."
2. The term "substantially surrounded laterally by infrared elements" in claim 12 is construed as: "substantially surrounded latitudinally by infrared elements." Cooper's proposed construction is "substantially surrounded on all sides." Dkt. # 61-2, at 28. Unitherm argues that this term does not require construction or, in the alternative, proposes "substantially surrounded from side to side by infrared elements." Dkt. # 60, at 23.

Cooper's suggestion that "surrounded laterally" means "surrounded on all sides" is impracticable. If a food product were surrounded on all sides by infrared elements its exit from a continuous oven would be blocked. At the Markman hearing, the parties agreed that "latitudinally" was an appropriate synonym for "laterally" in this case. From the nature of the inventive process and the drawing sheets, it is clear that the term is meant to refer to heating elements that are oriented along planes perpendicular to the food product's direction of travel.

11 Further, Cooper's proposed construction is at odds with its own proffered dictionary definition of the word "laterally," which is "of, relating to, or situated at or on the side." Dkt. # 61, at 25 (emphasis added).

The Court further finds that the term "infrared elements" does not require construction.

3. "Substantially surrounds" encloses completely or largely, at least sufficiently (in combination with other limitations) to prevent alteration of the cross-sectional configuration of the axle as referenced at col 5, ll. 28-30, col. 12, ll. 8-11; and col. 13, ll. 18-20. Turning to the phrase in claim 1 describing an inner chamber "being substantially symmetrical with said center of gravity," the term "symmetrical" as used in claim 1 can be defined by first looking at the term "said center of gravity." Claim 15 and the specification both define the "center of gravity" as a vertical plane transverse to the longitudinal direction of movement of the machine, between the wheel axle and the scrub brush. The center of gravity is to the rear of the wheel axis and substantially forward of the vacuum nozzles. The '891 patent, col. 4, lines 40-46 and col. 6, lines 31-36. The center of gravity in this case would describe a plane that divides the machine into halves of equal weight. A claim term "cannot be interpreted differently in different claims because the claim terms must be interpreted consistently." Southwall Technologies, Inc. v. Cardinal IG Co., 54 F.3d 1571, 1579 (Fed. Cir.), cert. denied, 133 L. Ed. 2d 424, U.S. , 116 S. Ct. 515 (1995). Accordingly, "center of gravity" in claim 1 refers to a vertical plane transverse to the longitudinal direction of movement of the machine that divides the machine into halves of equal weight.

8 Webster's Ninth New Collegiate Dictionary (1985) defines the term "center of gravity" as "center of mass," "the point at which the entire weight of a body may be considered as concentrated so that if supported at this point the body would remain in equilibrium in any position," or "a point, area, person, or thing that is most important or pivotal in relation to an indicated activity, interest, or condition." It is clear from the '891 patent that the term here refers to mass.
and the inner chamber full of clean water, or the inner chamber empty and the outer chamber full of spent water, or at any stage therebetween when both chambers contain water. As clean water is progressively depleted from the inner chamber, and spent dirty water fills the outer chamber, the hydrodynamic pressure of the dirty water causes the flexible walls of the inner chamber to collapse, while the center of gravity of the water remains substantially the same at the center of the inner chamber.

It is clear from the specification that there is only one center of gravity for the machine itself as well as the two chambers. The specification states that the centers of gravity of the two chambers coincide (occupy the same space) and lie centrally of the inner chamber. The '891 patent, col. 3, lines 64-66. Further, this center of gravity is a vertical plane. Claim 1 states that the inner chamber is substantially symmetrical with "said center of gravity," referring to the center of gravity of the machine. The inner chamber must therefore be symmetrical on either side of the vertical plane that divides the machine into halves of equal weight.

The patent does not define "symmetrical," and there is no indication that the term is meant to have any special meaning. Webster's Dictionary defines "symmetrical" as "capable of division by a longitudinal plane into similar halves." Therefore, each half of the inner chamber on either side of the center of gravity must be of a similar shape.

9 Webster's Ninth New Collegiate Dictionary (1985). The full definition is:

symmetrical or symmetric adj. 1: having, involving, or exhibiting symmetry 2: having corresponding points whose connecting lines are bisected by a given point or perpendicularly bisected by a given line or plane ([approximately] curves) 3: symmetric: being such that the terms or variables may be interchanged without altering the value, character, or truth (symmetric equations) 4 a: capable of division by a longitudinal plane into similar halves ([approximately] plant parts) b: having the same number of members in each whorl of floral leaves ([approximately] flowers) 5: affecting corresponding parts simultaneously and similarly ([approximately] rash) 6: exhibiting symmetry in a structural formula; esp.: being a derivative with groups substituted symmetrically in the molecule.

10 Plaintiff asserts that the definition of "symmetrical" determined by the court in Micro Motion, Inc. v. Exac Corp., 741 F. Supp. 1426, 16 U.S.P.Q.2d 1001 (N.D. Cal. 1990) should be applied to the present case. In Micro Motion the court defined "symmetrical" as referring to symmetry about an axis or line, rather than planar (mirror image) symmetry. However, Micro Motion dealt with a flowmeter patent, and the plaintiff here has given no evidence that a term used in the context of flowmeters would have the same meaning in the context of floor cleaners. Accordingly, this is extrinsic evidence that will not be considered by the court.

The patent teaches a floor cleaning machine with a center of gravity that remains substantially constant during operation. The method it teaches for keeping the center of gravity substantially constant employs a clean water chamber and a dirty water chamber which both share the same center of gravity. The center of gravity for the load as a whole remains balanced about the center of gravity during operation because the centers of gravity for both chambers, which share the same center of gravity with the machine, remain constant during operation. In other words, if the centers of gravity for the individual chambers do not shift, the center of gravity for the load as a whole will not shift either.

The preferred embodiment of the invention employs an inner chamber that appears from the side to be "generally spherical." The drawing also employs a spherical inner chamber, with the center of gravity running vertically through its center. While limitations in the specification are not to be read into the claims, Markman, 52 F.3d at 980, reference to the specification and drawings to interpret specific claim language is proper. General Amer. Transp. Corp. v. Cryo-Trans, Inc., 93 F.3d 766, 770 (Fed. Cir. 1996), cert. denied, U.S. , 117 S. Ct. 1334 (1997). Although the reservoir does not have to be spherical, it is apparent from the specification that the term "symmetrical" refers to the shape of the reservoir. 11 Even if the term referred to weight balance rather than shape, the requirement that the inner chamber balance its load of water on either side of the center of gravity would dictate a symmetrical shape. This is the most logical interpretation when reading the patent as a whole. Also, dependent claim 5 of the '891 patent describes an inner chamber of partial spherical configuration. Dependent claims can aid in interpreting the scope of claims from which they depend, but they are only an aid to interpretation and are

- 4615 -
not conclusive. North Amer. Vaccine, Inc. v. American Cyanamid Co., 7 F.3d 1571, 1577 (Fed. Cir. 1993), cert. denied, 511 U.S. 1069, 114 S. Ct. 1645, 128 L. Ed. 2d 365 (1994). The use of a spherical inner chamber in claim 5 supports a determination that the inner chamber in claim 1 must be symmetrical about the center of gravity, but not necessarily spherical. Interpreting "said inner chamber being substantially symmetrical with said center of gravity" as referring to shape would be a logical interpretation in light of the specification and claim 5.

11 The sphere is not the only symmetrical shape. The spherical inner chamber is merely the preferred embodiment.

Defendant argues that the term "symmetrical" refers to the fact that the clean water chamber located within the dirty water chamber positions the clean and dirty water, respectively, in substantially balanced proportion about the center of gravity of the machine in use. In other words, the defendant argues that the patent's description of a substantially constant center of gravity is limited to only the entire load of water, and does not focus on the center of gravity of either of the individual chambers. However, defendant's argument is unavailing. A court can neither broaden nor narrow a claim to give the patentee something different than what the claims set forth. Texas Instruments Inc. v. U.S. Int'l Trade Comm'n, 988 F.2d 1165, 1171 (Fed. Cir. 1993). In a cleaner where the two chambers do not share the same center of gravity, if the center of gravity of one chamber were to shift during operation, the center of gravity of the other chamber would also have to shift in the opposite direction in order to compensate if the center of gravity for the entire load is to remain substantially constant. This sort of configuration is beyond what is taught by the '891 patent, which clearly defines a machine where the two chambers share the same center of gravity. Indeed, the patent gives no hint as to how one could create a machine where the center of gravity for the machine remains substantially constant without inner and outer chambers that share the same center of gravity. Defendant argues that it makes no sense to focus on movement of the centers of gravity of the separate chambers. However, it is the centers of gravity in the separate chambers that enable one reading the patent to recreate it. If defendant's argument were accepted, it would impossibly broaden claim 1 beyond what is set forth. The patent cannot merely describe a floor cleaning machine that has a substantially constant center of gravity, but must also teach how to make it. 35 U.S.C. § 112. This the patent does, by teaching the use of inner and outer chambers that have centers of gravity that coincide. This is the only method taught--it does not teach at all how to make a machine with a substantially constant center of gravity where the centers of gravity of the inner and outer chambers shift. "A patent applicant cannot disclose and claim an invention narrowly and then, in the course of an infringement suit, argue effectively that the claims should be construed to cover that which is neither described nor enabled in the patent." North Amer. Vaccine, 7 F.3d at 1577. The patent simply does not contain enough information to enable the scope of the claims as argued by defendant. See In re Goodman, 11 F.3d 1046, 1050 (Fed. Cir. 1993).

This construction is consistent with the teachings of the patent and this claim is not invalid for indefiniteness. Plaintiff's motion for summary judgment on this contention is denied.

This opinion construes the term "said outlet being oriented relative to the liquid passageway so that the liquid being pumped passes through the outlet substantially tangentially relative to the longitudinal axis of the pump housing," which is found in U.S. Patent No. 5,833,437 ("the '437 Patent"). At the pre-trial hearing on August 31, 2010, the parties raised a claim construction issue regarding this phrase. The claim language reads:

1. A pump for pumping liquid comprising: a pump housing having opposing first and second end regions, a longitudinal axis and a plurality of ribs extending inwardly and located near the first end region, and defining a chamber; an inlet in said pump housing at said first end region; an outlet in said pump housing at said second end region; a motor housing extending into said chamber defined by said pump housing; a motor located in said motor housing; an impeller assembly operatively coupled to said motor for pumping liquid which enters said chamber through said inlet; and

- 4616 -
an impeller assembly operatively coupled to said motor for pumping liquid which enters said chamber through said inlet; and said pump housing, said motor housing and said impeller assembly together forming a liquid passageway from said inlet to said outlet, said outlet being oriented relative to the liquid passageway so that the liquid being pumped passes through the outlet substantially tangentially relative to the longitudinal axis of the pump housing.

Claim 1, Col. 8, L. 54-Col. 9, L. 7.

Shurflo argues that in reviewing the terms of Claim 1 in connection with the specifications and preferred embodiments, it is clear that the patentee intended for the liquid being pumped through the pump to pass through an outlet on the side of the housing (i.e. perpendicular to the pump housing). Shurflo contends that each of the figures in the '437 patent depict a perpendicular outlet essentially identical to the livewell pumps at issue in this case. Plntf's Br. At 3. Thus, the term cannot be read in strict mathematical terms, as doing so would exclude all of the preferred embodiments. Shurflo proposes the following construction:

the outlet being oriented substantially tangent to the liquid passageway so that the liquid being pumped passes through the outlet moving away from the longitudinal axis of the pump housing.

ITT contends "substantially tangentially" has a plain and ordinary meaning, and since that phrase is not otherwise defined in the patent, the plain meaning should apply. ITT argues that the plain meaning of "tangentially" is "aligned with the axis." Resp. Br. At 1. Therefore, using the plain meaning of "substantially tangentially," ITT contends the liquid being pumped through the pump must pass through an outlet extending upward from the pump housing and directly toward or away from an end of the pump. ITT proposes the following construction:

said outlet being oriented relative to the liquid passageway so that the liquid exits the pump through the outlet that extends upward from the longitudinal axis of the pump housing.

ITT argues that Shurflo ignores the claim language in favor of the specification. It is true that the claims of a patent are what define the invention. Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc) (quoting Innova/Pure Water Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1115 (Fed. Cir. 2004)). However, the "claims 'must be read in view of the specification, of which they are a part.'" Phillips, 415 F.3d at 1312-15 (quoting Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995) (en banc)). "[T]he specification 'is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.'" Id. (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)); Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002).

The heart of the parties' dispute regards what the patentee intended by describing the outlet direction as tangential to the longitudinal axis. Claim 1 and claim 11 (which depends from 1) recite three different orientations with respect to the claimed longitudinal axis: tangential, parallel, and perpendicular. Claim 1 requires "said outlet being oriented relative to the liquid passageway so that the liquid being pumped passes through the outlet substantially tangentially relative to the longitudinal axis of the pump housing." '437, claim 1. The patentee uses both "parallel" and "perpendicular" orientations in claim 11:

The pump of claim 1 which further comprises a dual inlet assembly secured to said pump housing, said pump housing having a longitudinal axis, said dual inlet assembly having a first port oriented parallel to the longitudinal axis so that liquid from said first port passes through said inlet and a second port oriented perpendicular to the longitudinal axis so that liquid from said second port passes through said inlet.

Col. 9, L.64-Col. 10, L. 4. Clearly, the patentee understands the difference between the words "parallel," "perpendicular," and "tangentially." Figures 2 and 4 in the patent are helpful in evaluating the particular meaning for these three orientations.

Both claim 11 and the specification refer to port 104 as parallel to the longitudinal axis 266. '437, 8:34-36 ("[d]ual inlet assembly 102 allows liquid to be passed through inlet opening 252 from a port 104 parallel to the longitudinal axis 266 of pump housing 212;" see also, Fig. 4). Both claim 11 and the specification refer to port 106 as perpendicular to the longitudinal access 266. Id. at 8:35-38 ("Port 106, which is perpendicular to longitudinal axis 266, is used for the inlet of a washdown pump (not shown) which is used periodically, when needed."). Finally, in describing the outlet port (54 in figure
2 and 254 in figure 4), the specification states that "opening 54 is situated so that the pumped liquid in liquid passageway 60 leaves or exits liquid passageway 60 substantially tangentially to the longitudinal axis 66 of the pump housing 12. This provides reduced resistance to the pumped fluid leaving the liquid passageway 60 and enhances pump efficiency." '437, 4:55-60.

In view of this guidance from the specification and claims, the Court finds that the parallel and perpendicular orientations are easily ascertained with respect to the two dimensional aspects of figure 4. The patentee used the term parallel to refer to a line or direction that is the same as the direction as the longitudinal axis. Further, the patentee used the term perpendicular to refer to a line or direction that is rotated 90 degrees from the direction of the longitudinal axis. However, when referring to the tangential orientation of opening 54 (or 254), the third dimension of figure 2 and figure 4-represented by the dotted-line nature of item 52 (or 254)-is important to note.

Obviously, port 54 (or 254) was not intended as literally depicted - a hole in the pump motor 20. Rather, the dotted line indicates that the opening extends from the fluid passage, back behind the pump motor in a direction that is generally tangential to an imaginary circle centered at the longitudinal access. In other words, if the longitudinal axis were a longitudinal cylinder, the opening 54 (or 254) would be generally tangential to an arc of that cylinder. For example, as shown in figures 2 and 4, the opening 54 (or 254) appears generally tangential to an arch formed by the outer surface of the cylindrical motor housing 18. Thus, the claim words "substantially tangentially relative to the longitudinal axis" are generally referring to a tangent of any arc of any cylinder centered on the horizontal axis. The Court finds that a line or direction is substantially tangential to the longitudinal access if that line or direction is: on one side of the longitudinal axis (thus a tangent to a axis-centered cylinder, where the cylinder has a positive radius of any value); and is not directly toward or away from the claimed end region of the pump (which would be parallel to the longitudinal axis).

Neither the patent's embodiments nor the claim words can support ITT's suggestion that the outlet must guide the fluid "upward from the longitudinal axis of the pump housing." ITT's proposed construction would require the pump outlet to guide fluid in a direction that is at least generally parallel to the claimed longitudinal axis. The claimed tangential direction is not parallel and not even necessarily generally parallel to the longitudinal axis. Further, Shurflo's proposal would include a strictly perpendicular orientation with respect to the longitudinal axis. As the Court indicated above, in order to be substantially tangential to the longitudinal axis, the fluid direction must be substantially on one side of the axis (i.e. a simple line perpendicular to the axis line is not a tangent to the axis) In addition, Shurflo's proposal does not resolve the dispute between the parties because it leaves the disputed word "tangent" within the construction.

Based on the Court's review of the claim language, the specification, and the parties' arguments, the Court construes the term "said outlet being oriented relative to the liquid passageway so that the liquid being pumped passes through the outlet substantially tangentially relative to the longitudinal axis of the pump housing" as follows: "the outlet is designed and positioned so that liquid passing though the outlet is moving in a direction that is both (i) substantially on one side of the longitudinal axis; and (ii) not directly toward or away from either end region of the pump housing."

1. Claim Construction

In construing claims, a Court examines how a person of ordinary skill in the art would have understood the claim terms at the time of the invention. Pfizer, 429 F.3d at 1372-73.

The inquiry into how a person of ordinary skill in the art understands a claim term provides an objective baseline from which to begin claim interpretation. Importantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification.

Id. at 1373 (quotation and citation omitted). The Court looks initially only at intrinsic evidence, including the claims themselves, the specification, and the prosecution history, if it is presented. Phillips v. AWH Corp., 415 F.3d 1303 (Fed. Cir. 2005). "[T]he claims are of primary importance, in the effort to ascertain precisely what it is that is patented." Id. at 1312 (quoting Merrill v. Yeomans, 94 U.S. 568, 570, 24 L. Ed. 235, 1877 Dec. Comm'r Pat. 279 (1876)). "[I]t is unjust to the public, as well as an evasion of the law, to construe [a claim] in a manner different from the plain import of its terms." Id.
Defendants that the taper angle needed to be 30 degrees or greater to be "substantial," was perplexing. As the Court has often inconsistent with the intrinsic evidence. The testimony of Mr. Tarr, who ultimately discredited the position taken by McKinney and Mr. Parkes, on behalf of Plaintiff, and Mr. Tarr, on behalf of Defendants, all sought to provide testimony that was not helpful in interpreting the claim and only marginally helpful in understanding the systems generally. Both Mr. Moreover, the Court found the testimony the experts presented to be confusing, incomplete and unpersuasive. In short, it appeared at the hearing, the Court concludes it is unnecessary and impermissible to do so. Phillips, 415 F.3d at 1316.

4 To the extent either party urges the Court to rely on extrinsic evidence, including the testimony of the experts who appeared at the hearing, the Court concludes it is unnecessary and impermissible to do so. Phillips, 415 F.3d 1303; Zodiac Pool Care, Inc., 206 F.3d at 1414. The intrinsic evidence provides an adequate and compelling basis to interpret the claim. The Court has reviewed the patent as a whole, including the specification and particularly the usage of "substantially" in the eight (8) instances it occurs in Claim One. The Court found the testimony the experts presented to be confusing, incomplete and unpersuasive. In short, it was not helpful in interpreting the claim and only marginally helpful in understanding the systems generally. Both Mr. McKinney and Mr. Parkes, on behalf of Plaintiff, and Mr. Tarr, on behalf of Defendants, all sought to provide testimony that essentially was their construction of the claim. To the extent they provided other expert opinion or factual evidence, it was often inconsistent with the intrinsic evidence. The testimony of Mr. Tarr, who ultimately discredited the position taken by Defendants that the taper angle needed to be 30 degrees or greater to be "substantial," was perplexing. As the Court has

"Words of a claim are generally give their ordinary and customary meaning." Id. (citing Vitronics Corp., 90 F.3d at 1582). "Ultimately, the interpretation to be given a term can only be determined and confirmed with a full understanding of what the inventors actually invented and intended to envelope with the claim. The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction." Phillips, 415 F.3d at 1316.

"Claims must be construed so as to be consistent with the specification, of which they are a part." Merck & Co., Inc. v. Teva Pharms. USA, Inc., 347 F.3d 1367, 1370 (Fed. Cir. 2003)."[I]t is necessary to consider the specification as a whole, and to read all portions of this written description, if possible, in a manner that renders the patent internally consistent." Pfizer, 429 F.3d at 1373. The principal of internal consistency is particularly acute here where the term at issue -- "substantially" -- is used eight (8) times within Claim One. Indeed, "[a] word or phrase used consistently throughout a claim should be interpreted consistently." Phonometrics, Inc. v. Northern Telecom, Inc., 133 F.3d 1459, 1465 (Fed. Cir. 1998). Our examination of the term then must begin with its use in the claim itself, because the usage in these eight (8) instances likely will be instructive, and maybe even controlling, in interpreting the term consistently. The eight (8) usages are:

1. "a substantially planar upper surface of the first slab" ("760 Patent, Col. 6, 11. 66-67.)
2. "substantially perpendicularly to the inner surface of the edge form" (Id., Col. 6, 1. 67 -- Col. 7, 1. 1.)
3. "a load plate including a substantially tapered end" (Id., Col. 7, 1. 5.)
4. "a load applied to either slab directed substantially perpendicularly to the upper surface of the first slab" (Id. Col. 7, 11. 8-10.)
5. "restricts relative movement between the first and second slabs in a direction substantially perpendicular to the upper surface of the first slab" (Id. Col. 7, 11. 11-14.)
6. "allowing the first and second slabs to move away from each other in a direction substantially perpendicular to the inner surface of the edge form" (Id. Col. 7, 11. 15-17.)
7. "width of the load plate being: substantially greater than or equal to the length of the load plate" (Id. Col. 7, 11. 21-23.)
8. "Increasingly greater relative movement of the first and second slabs in a direction substantially parallel to the longitudinal axis of the joint" (Id., Col. 7,11. 26-28.)

The parties agree that the claim construction issue here concerns that portion of Claim One relating to the dowel plate. The claim reads: "a load plate including a substantially tapered end. . . ." ("760 Patent, Col. 7, 1. 5.) Plaintiff argues this portion of the claim should be construed as: "The end of the load plate has a gradual diminishing width that is not insubstantial, i.e. the diminishing width is large enough to allow relative movement of two concrete slabs." (LPR 6.3 Joint Claim Construction Statement [105] at 2.) Defendants submit the construction should be: "An end that is tapered to a large or considerable degree; greatly tapered." (Id. at 3.) Defendants have quantified the taper arguing that what is required is a taper of 30 degrees or greater. (Defs.' Supplemental Opp'n to Pl.'s Mot. for Prelim. Inj. at 7-8.)

The Court has reviewed the patent as a whole, including the specification and particularly the usage of "substantially" in the eight (8) instances it occurs in Claim One. This usage of the word in Claim One alone strongly supports the conclusion that the term "substantially" means "essentially, having the principal characteristic of." This construction permits the term to be defined uniformly within the claim and the patent as a whole, and this construction otherwise makes legal and functional sense. 4
noted, a numerical limit here is not appropriate in light of the intrinsic evidence and the language of the patent as a whole. That Defendants presented inconsistent constructions to this Court persuades the Court that its reliance on intrinsic evidence and its decision not to rely on extrinsic testimony is sound.

The term "substantially" is not uncommon in patents. "Words of approximation, such as generally' and substantially' are descriptive terms commonly used in patent claims to avoid a strict numerical boundary to the specified parameter." Anchor Wall Sys. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1310-11 (Fed. Cir. 2003) (quotation and citation omitted). To the extent the term "substantially" has been interpreted to have more than one meaning, the "cases recognize the dual ordinary meaning of this term as connoting a term of approximation or a term of magnitude." Deering, 347 F.3d at 1323. Choosing between these two descriptive definitions is not difficult here. The intrinsic evidence urges interpreting the term "substantially" as a term of approximation because this usage makes practical common sense and allows the term to be defined consistently in each instance it is used in Claim One and elsewhere in the patent, including the specification. Simply substituting the approximation definition proves this definition fits:

1. [essentially, having the principal characteristic of having a] planar upper surface ('760 Patent, Col. 6, 11.66-67.)
2. [essentially, having the principal characteristic of being] perpendicular to the inner surface of the edge form (Id., Col. 6, 1. 67 -- Col. 7, 1. 1.)
3. [essentially, having the principal characteristic of having a] tapered end (Id., Col. 7, 1. 5.)
4. [essentially, having the principal characteristic of being] parallel to the longitudinal axis of the joint (Id., Col. 7, 11. 26-28.)

5 This construction simply makes logical, legal and linguistic sense. 6

5 While the Court has not used extrinsic evidence, it notes that the Court's definition is consistent with the prevailing dictionary definition of the word "substantial." See Blacks Law Dictionary 1428 (6th ed. 1990) ("essentially, without material qualification, in the main."); Webster's Collegiate Dictionary (10th ed. 1999) ("consisting of or relating to substance; important, essential").

6 The Federal Circuit has stated that "like the term about,' the term substantially' is a descriptive term commonly used in patent claims to avoid a strict numerical boundary to the specified parameter." Ecolab, Inc. v. Envirotech, Inc., 264 F.3d 1358, 1367 (Fed. Cir. 2001); Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 904-05 (Fed. Cir. 2005) ("substantially" should not be interpreted as having a strict numerical limitation). A definition based on magnitude cannot be uniformly or consistently applied in this particular patent.

Thus, using intrinsic evidence, this Court construes the term "substantially tapered end" in Claim One to mean an end which essentially, has the principal characteristic of being tapered. This definition also is consistent with the function of the Plate. The 760 Patent provides that the purpose of the system and the fundamental role played by the Plate is to avoid binding and to allow load transfer by a void being created around the plate so to permit movement parallel to the longitudinal axis. Both parties agree the taper allows this transfer to occur and also avoids binding. Having construed this claim term based on intrinsic evidence, and having tested the construction in its application throughout the 760 Patent, the Court concludes PNA has a substantial likelihood of success in proving Defendants' Plate is substantially tapered and thus literally infringes the 760 Patent. 7 8

7 To the extent Defendants contend the Court should limit its construction to the preferred embodiment described in this patent, the Court declines to do so. "Claims of a patent may only be limited to a preferred embodiment by the express declaration of the patentee." Playtex, 400 F.3d at 908.

8 Defendants' argument that the Court should adopt a "greater than 30 degrees taper" is inconsistent with the language of this patent. When the patent seeks to impose a numerical limit, it does so. (See Claim 2 ("less than one-eighth of a largest width"); Claim 23 ("no less than twice a depth."); Claim 26 ("an angle of approximately 45 degrees").)
All claims call for two ornamental components of "substantially the same size and configuration." Parties differ as to what implication the phrase has for the location of the hinge that joins the two components together. Citing the prosecution history, Defendants claim that the hinge must be located exactly at the "6'o clock" position on the earring. Zettl insists that while the hinge must be "centrally" located, the term allows for some leeway and does not prescribe a precise or exact location.

The appropriate starting point in interpreting a claim is always the language of the asserted claim itself. Comark Comm., Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998). In this case, there is no need to divine the location of the hinge through an interpretation of the phrase "substantially the same size and configuration" because the claims themselves go on to inform the reader exactly where the hinge must be. Claim 1 reads:

An ear ornamentation for wearing on and removable from a perforated ear lobe comprising two ornamental components of substantially the same size and configuration linked by means of a hinge at one end and having engageable fastening means at the other end of each said ornamental component.

(emphasis added). Therefore, according to the patent itself, the hinge must be located at the ends of both similarly sized ornamental components, opposite the end supporting the fastening means, joining the two pieces together. Since the terms of the claims are clear, the Court rejects the parties proffered definitions relying on positional terms such as "6'o clock" or "central" that, frankly, has little meaning in this context without clear reference points.

1. "Cylindrical wall portions radially spaced from the end portions of the substrate projecting beyond said mat for a distance substantially the same as that of the projecting ends of the substrate." Consistent with the claim language and its ordinary meaning, 43 and the specification, 44 the court construes "cylindrical wall portions radially spaced from the end portions of the substrate projecting beyond said mat for a distance substantially the same as that of the projecting ends of the substrate" to mean "the distance between the inner wall of the enlarged diameter tubular body and the catalyst substrate is largely, though not exactly, the same distance the substrate extends beyond the mat."

--- Footnotes ---

43 D.I. 151, ex. E at 1176 (defining "substantial" as "being largely but not wholly that which is specified").

44 '476 patent, col. 2, ll. 54-57; col. 3, ll. 15-18; col. 4, ll. 16-20.

--- End Footnotes ---

"The prescribed absorbed dose is delivered to the target tissue in substantially three dimensions"

Cytsc's proposed construction Xoft's proposed construction
The prescribed absorbed dose is delivered to the target tissue such that all points at a given outward distance from the tissue wall will receive the same dose.

(indefinite)
Xoft contends that "prescribed absorbed dose" and "in substantially three dimensions" render "the prescribed absorbed dose is delivered to the target tissue in substantially three dimensions" fatally indefinite. The court has already rejected Xoft's argument regarding "prescribed absorbed dose."

Xoft points to Cytyc's expert's testimony that "there's no such thing as substantially three dimensions" because something is either three dimensional or not. Mulville Decl. (dkt. # 51), Ex. L (Verhey Decl.) at 153. Cytyc points to Xoft's expert's testimony that he could envision a brachytherapy apparatus that delivered 99 percent of its radiation in a plane; Cytyc claims such a flat radiation field would not be in substantially three dimensions. Though a closer question than some of Xoft's other indefiniteness contentions, the court nonetheless finds that Xoft has not shown by clear and convincing evidence that one skilled in the art would not understand "in substantially three dimensions" in the manner put forth by Cytyc.

The court therefore adopts Cytyc's proposed construction for "the prescribed absorbed dose is delivered to the target tissue in substantially three dimensions," namely, "the prescribed absorbed dose is delivered to the target tissue such that all points at a given outward distance from the tissue wall will receive the same dose."

---

5. "transferred substantially to the reaction frame"

It is clear from the specification language that the central aim of the '500 patent invention is the prevention of reaction forces reaching--and thereby negatively impacting--the precision components of the photolithographic projection system. See '500 Patent at Abstract. Claim 1's language captures this aim, noting that reaction force is to be "transferred substantially to the reaction frame." The court has already construed the term "reaction frame," reading the phrase to mean "a physical structure, separate and distinct from the structure supporting the precision components, that transfers reaction forces, caused by the movement of a stage drive, away from the precision components." Thus, it remains only to construe "transferred substantially."

Simple etymology suggests that "transferred" connotes the direction to, passage from, or exposure of one item to another. "Substantially," in turn, "means what it says[--]largely, but not" entirely. See Ecolab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1369 (Fed. Cir. 2001) (construing the term "substantially uniform"). Taken together, "transferred substantially" denotes precisely what the phrase would mean in common parlance: "the movement or direction of most, but not necessarily all, of a particular entity to another." The court need not venture from this plain meaning here, and the court thus construes "transferred substantially to the reaction frame" to mean "the movement or direction of most, but not necessarily all, of the reaction force to a physical structure, separate and distinct from the structure supporting the precision components, that transfers reaction forces caused by the movement of a stage drive away from the precision components."

---

A. Substantially Toroidal Flow Path

Starting with the claim language, the element in dispute does not describe the "flow path" as circular or curved, but as "substantially toroidal." The specification is replete with references to "toroidal" in terms of the "housing" and the resulting "flow path," but refers as well to a "curved" flow path:

The doughnut-like curvature provides a toroidal channel or tunnel through which entering fluid is guided. The toroidal
housing cover forms a coil-like tunnel which is enlarged approximately 180 [degrees] from a blood inlet port provided at one end of the toroid-shaped housing cover. This enlarged area defines the highest point on the housing cover. A gas vent is located at the highest point on the toroidal tunnel, at the periphery of the housing cover.

Fluid enters the tangential blood inlet and circulates through the toroidal channel. As the fluid flows about the toroidal channel, gaseous matter is drawn upward by buoyant forces and is allowed to escape through the peripheral gas vent, while the fluid seeps down into a reservoir formed between the inner wall of the housing cover and the outer perimeter of the cylindrical filter element. The gentle swirling action of the entering fluid through the toroidal channel is sufficient to cause the fluid to flow completely about the housing cover and seep down around the sides of the filter element.

(Col. 2, Ins. 47-65) (emphasis added).

The toroidal configuration provides a smooth, curved flow path of maximum radius to minimize or reduce aggressive agitation of the fluid during its flow. Due to the central indentation 22 defined by the toroid-shaped housing cover 14, the curved fluid flow path is radially spaced from the central axis of the housing 12. This allows the radius of curvature of the fluid flow path (and, thus, the length of the path) to be maximized, while containing the path within the housing cover. Maximizing the length of the fluid flow path tends to maximize the time period in which a given volume of fluid flows through the length of the path (for a given flow velocity) and, therefore, maximizes the amount of time in which gas bubbles may be drawn from the fluid.

The curved fluid flow path also tends to gently guide the fluid around the upper periphery of the underlying filter element 16, such that the fluid can flow downward around substantially the entire outer peripheral surface of the filter element and then pass through the filter element to all radial directions with minimal agitation and turbulence. Consequently, the undesired generation of air bubbles is also minimized. This allows the entire filter element to be efficiently used and maximizes the rate at which a given volume of fluid may be passed through the filter element.

Referring to FIGS. 1, 2 and 4, the toroid-shaped housing cover 14 is configured to guide fluid (not shown) in a curved path over the filter housing 12 as it enters the arterial filter 10 . . . .

The housing cover 14 has a toroidal, doughnut-like shape. The height of the toroid 34 forming the housing cover 14 rises as it curves about the perimeter of the housing cover 14. As shown in FIGS. 2-4, the highest point of the housing cover 14 is located midway around the toroid curvature, approximately 180 [degrees] from the tangential inlet port 18.

A gas vent cap 20 is located at the perimeter of the housing cover 14, at the highest point on the cover, opposite the inlet port 18. The side view of the arterial filter 10 depicted in FIGS. 2 and 4 show a preferred arrangement of the gas vent 20 disposed on the highest point on the toroidal channel, at the periphery of the housing cover 14. In the preferred embodiment, the gas vent 20 is a one-way valve, such as a female Luer cap, which allows gas to escape but does not permit air or particulate matter to enter.

Because the gas vent 20 is located at the highest point on the toroid-shaped housing cover 14, approximately 180 [degrees] opposite the tangential inlet port 18, as the inlet liquid is caused to swirl through the toroidal channel 34, gaseous matter rises, by buoyant forces, to the highest point of the filter and exits through the gas vent 20. Yet, due to the swirling action, the inlet fluid still retains sufficient momentum to flow through the remaining half of the downwardly sloping toroidal channel to flow steadily and evenly around the perimeter of the toroidal channel of the housing cover 14, before seeping downward into the housing reservoir 32. This feature is discussed in more detail below.

FIG. 4 also illustrates an indentation 22 formed in the center of the toroid-shaped housing cover 14. As discussed in more detail below the indentation 22 serves to stabilize and support the filter element 16 as well as provide clear visibility of the filtered fluid after it passes through the filter element 16 into the central cavity 36 of the filter element 16. The configuration of the housing cover 12 and the indentation 22 comprises an inverted dome cap which, in preferred embodiments, defines a toroidal-shaped fluid flow path.

(Col. 4, Ins. 20-67; col. 5, Ins 1-23) (emphasis added).

In operation, the toroid-shaped housing cover 14 acts as an air separation chamber. When a fluid, e.g., a priming fluid or
blood, enters the tangential inlet port 18 via a tube or other fitting, it flows tangential to the wall of the toroidal channel 34 and through the curved path defined by the channel. The flowing motion creates a gentle swirling action which causes air and other gaseous matter to be separated from the fluid inside the toroidal channel 34. Consequently, in accordance with the principles of buoyancy, the gaseous matter rises and escapes through the peripheral vent cap 20 which is located on the highest point about the toroidal channel 34. As the gaseous matter is separated from the fluid, the swirling debubbled fluid seeps downward from the periphery of the toroidal tunnel 34, over the potting 30 and the filter element 16, and into the reservoir 32 formed between the inner wall of the housing 12 and the outer perimeter of the filter material 16, as shown in FIG. 4 . . . . (Col. 7, lns 25-42) (emphasis added).

The prosecution history of the '474 patent was included in the record as well. The claims at issue were initially rejected by the Examiner under 35 U.S.C. § 102 and § 103 by reason of a certain prior art reference (the "Siposs '135 patent") which showed, according to the Examiner, a "toroidal flow path" evidenced by the fact that Siposs repeatedly refers to a rotating fluid flow path created in the filter device. . . . (D.I. 71, Ex. D at 3; Ex. F at 3) Bard responded to such rejection as follows:

Siposs does not appear to have expressly recognized a "toroidal flow path" occurring within the "circular" chamber 54, much less any benefit of enhancing such "toroidal flow path." (Siposs does not appear to mention the term "toroidal.") Siposs teaches a conical cap interior with a central apex defining the highest elevation for channeling gas to the central vent 48. A central indentation in the cap would destroy Siposs' intended operation of congregating gas in the center of the chamber. . . . Thus, Siposs provides no suggestion of (and teaches away from) a central indentation and a laterally offset gas vent as claimed. . . .

According to Siposs, fluid enters a circular chamber tangentially so as to create a rotation of the fluid about the circular chamber to separate gas therefrom. As the fluid rotates around the circular chamber, the lighter gas bubbles purportedly "congregate in the center of the chamber" . . . . Thus, Siposs' device purportedly operates under principles of centrifugal force, wherein the rotation of the fluid within the circular chamber causes the heavier fluid to flow near the peripheral wall of the chamber, while lighter gas bubbles congregate toward the center of the chamber.

(D.I. 71, Ex. E at 13, 16) (emphasis in original).

The '474 claims eventually were allowed as presently written after an unrecorded telephone interview. The Examiner apparently concluded that the independent claims would be distinguished from the art of record if amended to include limitations of various dependent claims. For example, claim 25 (now claim 1) was amended as follows (underlined language indicates added language):

1. [O>25.<O] (TWICE AMENDED) A filter for filtering fluids, comprising:

a housing defining a substantially toroidal flow path and a filter element chamber;

a fluid inlet in fluid flow communication with the substantially toroidal flow path and directed substantially tangential to the fluid flow path; wherein the height of the substantially toroidal flow path rises from the location of the inlet, around the periphery of the housing to a highest point located approximately 180 [degrees] opposite the fluid inlet;

a gas outlet aperture located at the highest point on the substantially toroidal flow path; and in gas flow communication with the substantially toroidal flow path and located approximately 180 [degrees] from the fluid inlet with respect to the substantially toroidal flow path;

a filter element supported within the filter element chamber of the housing; [and]

a filter element support located within the housing and centrally disposed with respect to the toroidal flow path; and
a fluid outlet in fluid flow communication with the filter element chamber.

(D.I. 71, Ex. I at 1-2) Consistent with Bard's summary reproduced below, it appears as though the focus of the review process was on the location of the gas outlet, not on the significance of a "toroidal flow path."

It is respectfully submitted that a filter having the combination of a toroidal flow path, a fluid inlet tangentially directed with respect to the toroidal flow path, and a gas outlet as defined in the above-noted claims is neither described nor suggested by the prior art of record. Siposs describes a filter having a centrally located gas outlet and provides no disclosure or suggestion of the above-referenced combination of features, including a gas outlet located 180 [degrees] from the fluid inlet . . . directly above the toroidal flow path . . . or laterally offset with respect to a central portion of the housing cap. . . .

(D.I. 71, Ex. I at 10)

As far as the court can discern from the record, the phrase "substantially toroidal flow path" means either a circular flow path (as asserted by Bard) or a flow path defined by a toroidal structure (as asserted by Medtronic). 2 Based on the principle that every word in a claim should be given its ordinary meaning, and fully cognizant of the proscription against limiting claims by what is disclosed in a preferred embodiment, the court concludes that Medtronic's construction is the proper one. The definition of a toroid encompasses two features: (1) a closed curve; (2) rotating about, but not intersecting or containing, an axis in its own plane. Webster's Third New Int'l Dictionary 2412 (1971). Accord Adelphon, Inc. v. DiRico, 1992 U.S. Dist. LEXIS 15298, *1-2, No. CA 3-91-2551- T, 1992 WL 281395, at 3 n.1 (M.D. Tex. Mar. 26, 1992) Bard's contention that the phrase "substantially toroidal" means only "circular" essentially allows a nontechnical word ("substantially") to negate the meaning of a technical word ("toroidal"). The court considers such an interpretation to be inappropriate.

2 It appears from the specification and, particularly, from figures 1, 2, and 4, that the "toroidal channel" of the preferred embodiment is not a closed curve (it is flat at the bottom) and, therefore, is a "substantially toroidal" structure.

The above construction is supported by and consistent with the intrinsic evidence of record. Looking at the claim language in light of the specification and the prosecution history, the '474 patent is distinguished from the prior art because its housing "define[s] 3 a substantially toroidal flow path." As recognized in the prosecution history, prior art devices which employed a tangential entry into a cylindrical chamber achieved, to some extent, a circular flow path. Such a flow path, albeit circular, is not bounded by a "closed curve" but, rather, by a cylindrical wall. Neither does such a flow path rotate about, but not intersect, a discernable axis. (See, for instance, D.I. 71, Ex. E at 13, 16) Accordingly, the claim language - "substantially toroidal flow path" - is construed to mean a fluid path defined by a toroidal (or substantially toroidal) structure.

3 To define means: "to mark the limits of: determine with precision or exhibit clearly the boundaries of." Webster's Third New Int'l Dictionary 592 (1971).
evidence, the prosecution history. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2d (BNA) 1573, 1576-77 (Fed. Cir. 1996). If intrinsic evidence resolves all ambiguities, extrinsic evidence is not considered. See id.

The district court initially construed "a housing defining a substantially toroidal flow path" as meaning "a fluid path defined by a toroidal (or substantially toroidal) structure." C.R. Bard, Inc. v. Medtronic, Inc., 1998 U.S. Dist. LEXIS 23197, at *18, C.A. No. 96-589-SLR, slip op. at 15 (May 7, 1998) (Memorandum Order). The court reconsidered and revised this claim construction, however, after considering Bard's arguments that the recited "flow path" was not a structural path, but was the path followed by the fluid. The court tentatively accepted Bard's assertion that a substantially toroidal flow can occur in a non-toroidal housing, and construed the phrase as requiring "that the housing (although not necessarily toroidal in shape) must determine with precision a fluid flow path having the shape of a substantially closed curve which rotates about, but does not intersect or contain, an axis in its own plane." C.R. Bard, Inc. v. Medtronic, Inc., 1999 U.S. Dist. LEXIS 9875, C.A. No. 96-589-SLR, slip op. at 3-4 (June 15, 1999) (Memorandum Order).

Medtronic argues that the district court's construction is erroneous because a flow path can only exist as a consequence of defined boundaries; accordingly, to define a toroidal flow path, the housing must be toroidally shaped. Medtronic also argues that the specification of the '474 patent describes the housing as having a toroidal structure, and does not describe a housing having any other shape.

Bard replies that the '474 patent makes clear that it is the flow path, not the housing, that must be toroidally shaped. Bard points to column 4, lines 18-20, of the patent, which state that "shapes other than a toroid may be used." Bard also contends that interpreting the "housing" limitation as requiring a toroidally shaped housing would violate the doctrine of claim differentiation because claim 2 specifically recites that "the housing further defines a central indentation, centrally located with respect to the substantially toroidal flow path."

The '474 patent consistently describes the housing as being "doughnut or toroid-shaped." See, e.g., '474 pat., col. 2., ll. 37-38, col. 4, l. 3, col. 4, ll. 45-48, col. 4, l. 55, col. 5, l. 16, col. 7, l. 6, col. 7, l. 26, col. 8, ll. 9-12. The patent describes the advantage of the toroid shape as follows:

The toroidal configuration provides a smooth, curved flow path of maximum radius to minimize or reduce aggressive agitation of the fluid during its flow. Due to the central indentation 22 defined by the toroid-shaped housing cover 14, the curved fluid flow path is radially spaced from the central axis of the housing 12. This allows the radius of curvature of the fluid flow path (and, thus, the length of the path) to be maximized, while containing the path within the housing cover. Maximizing the length of the fluid flow path tends to maximize the time period in which a given volume of fluid flows through the length of the path (for a given flow velocity) and, therefore, maximizes the amount of time in which gas bubbles may be drawn from the fluid.

Id. at col. 4, ll. 20-34. See also id. at col. 5, ll.8-14, col. 7, ll. 25-42.

In view of these teachings, we disagree with the district court's determination that the housing itself need not be toroidally shaped. Although the patent states that "shapes other than a toroid may be used for further embodiments," id. at col. 4, ll. 18-19, it does not indicate that a housing of any other shape would "define a substantially toroidal flow path," as recited in the claims. The only structure described in the patent as providing a toroidally shaped flow path is a toroidally shaped housing. We therefore construe the "housing" limitation as requiring that the housing itself be toroidally shaped.

This interpretation does not make claim 2 redundant, as Bard argues, because a toroidally shaped housing need not necessarily have a central indentation, as recited in claim 2. Moreover, this interpretation is consistent with the '474 patent's use of the word "define" to describe structural features of the housing. For example, claim 2 uses the phrase "the housing . . . defines a central indentation" to recite a housing having an indentation in its lid. This interpretation also is consistent with the claims' use of the term "toroidal flow path" to refer to a structural feature of the housing, not merely a path taken by fluid inside the housing. For example, claim 1 refers to "the height of the substantially toroidal flow path," and a "gas outlet located at the highest point on the substantially toroidal flow path."
B. Effect of Prior Litigation

As stated above, SunTiger prevailed in a prior patent infringement suit against Scientific Research Funding Group (SRFG) on the same patents now in question. Both SunTiger and Sunglass Products have stipulated that the claim construction in the prior suit will control here:

The patents-in-suit have already been construed by the U.S. District Court for the Eastern District of Virginia [and that] construction . . . is binding on the parties in this case. To the extent that the terms in the asserted claims were not construed in the said prior litigation, the parties are asking the Court to make a claim construction based on the arguments submitted in the summary judgment motions.

Stipulation at 1-2. "In a patent litigation action, where the parties do not dispute any relevant facts regarding the accused product but disagree over possible claim interpretations, the question of literal infringement collapses into claim construction and is amenable to summary judgment." Rheox, Inc. v. Entact, Inc., 276 F.3d 1319, 1324 (Fed. Cir. 2002).

The relevant terms and their stipulated construction are as follows:

<table>
<thead>
<tr>

Plaintiff SunTiger contends that this Court cannot apply the stipulated construction in a way that would contradict the finding of the Eastern District of Virginia that YE-82 infringed SunTiger's patents. Pl.'s Mot. at 1 ("[T]he YE-82 lens material must literally infringe whatever claim construction the Court adopts in this case."). In essence, SunTiger argues the following: (1) the parties have stipulated to the prior construction, (2) the decision in the prior suit does not bind this Court,
but (3) any ruling that this Court issues must not be inconsistent with the fact that YE-82 was found to infringe its patents.

I disagree with this assessment. My decision is not foreordained by the result in SunTiger, Inc. v. Scientific Research Funding Group. SunTiger attempts to elevate the prior claim construction to the level of a decision. Despite the parties' agreement that the prior claim construction would be binding, that prior court's decision applying its own construction is only persuasive. Although the parties have agreed to be bound to the use of the prior construction, they have not agreed that this Court's application of that construction must be consistent with prior decisions involving a different defendant and different lenses. Indeed, were consistency with prior results necessary, that would be tantamount to an improper form of collateral estoppel against a current party, i.e., Sunglass Products, which was not a party (nor a party in privity) to SunTiger v. Scientific Research Funding Group, Cf. MCA Records, Inc. v. Charly Records, Ltd., 865 F.Supp. 649, 654 (C.D. Cal. 1994) ("[D]ue process requires that the party to be estopped must have had an identity or community of interest with, and adequate representation by, the losing party in the first action as well as that the circumstances must have been such that the party to be estopped should reasonably have expected to be bound by the prior adjudication.").

3965

5. "substantially transparent to visible light"

This term appears in claim 1 of the '529 and '660 patents. According to the Chart that was submitted with the claim construction briefing, this claim term is undisputed. However, at the Markman hearing the parties indicated that, in fact, the construction of this phrase is disputed. The parties dispute the construction of the term for essentially the same reason in each patent. Plaintiff's proffered construction is as follows: "light in the visible range of the spectrum can transmit through the dispersion when applied in use." Chart at 5, 21. Kobo's proposed construction is fairly similar: "light in the visible range of the spectrum substantially passes through a sample of the dispersion." Chart at 5. The difference between the two constructions boils down to whether the dispersion must be substantially transparent when the product is in use (e.g., when applied to the skin as a sunscreen) or substantially transparent when it is, for example, in a jar.

7 Kobo offers this construction only for the term as it appears in the '660 patent. The Chart does not contain a proposed construction by Kobo for this term in the '529 patent. Chart at 21.

The Court finds that, when read in light of the specification, the phrase "substantially transparent to visible light" should be construed consistent with Plaintiff's proffered construction. The specification notes that the "products of the present invention have the ability to transmit visible light but are partially or completely impermeable to UV light." '660 patent, col. 2, lines 46-48. The specification goes on to explain that "[t]his means that the products can find use in a variety of applications wherein it is important to maintain transparency to visible light while substantially preventing transmission of UV light to a surface." Id., col. 2, lines 48-52. Examples given include "[c]osmetics, sun-creams, plastic films and wood coating and other coating compositions." Id., col. 2, lines 52-54. It is clear that the transparency during use, not necessarily transparency in the jar, is a significant feature the invention.

Indeed, Defendant's own briefing supports the Court's conclusion. In the section of its opening claim construction brief that is titled "Background of the Technology," Kobo notes that modern sunscreen dispersions have the characteristic of being "transparent to visible light, and thus invisible on the skin." Def. Brf. at 4. Kobo goes on to explain that "[t]ransparent to visible light means that when the sunscreen is applied to the skin, it appears clear and thus does not whiten the skin." Id. at 5 (emphasis added). In describing the development of smaller and more transparent grades of titanium dioxide and zinc oxide used in sunscreens, Kobo notes that "these smaller sunscreen pigments are transparent to visible light, which means that when they are applied to the skin, they appear to be transparent to the human eye and thus do not alter the appearance of the skin." Id. (emphasis added).

Consequently, the Court shall construe the phrase "substantially transparent to visible light" in both patents to mean "light in the visible range of the spectrum can transmit through the dispersion when applied in use."
1. Claim Construction

The first step in the analysis is to determine, as a matter of law, the meaning and scope of the patent claims. As described above, Defendant Sashco's '458 patent is directed to a substantially transparent combination of a cartridge and compound. The only independent claim in the patent emphasizes that this combination "is substantially transparent in the transverse direction so as to allow a user to see completely through... from one side of the cartridge to the other." This Court must now determine whether this claim, when properly construed, is limited to situations wherein a user can see through the center of the cartridge, as argued by the Plaintiff, or whether it encompasses situations in which a user can see completely through any other portion of the cartridge's sidewall, which is the construction urged by the Defendant. 

7 For example, Defendant attached pictures to its Motion for Partial Summary Judgment which showed that one can view through the Plaintiff's product and see a colored line which is taped to the wall behind the cartridge (Doc. # 61, Exh. J). One cannot, however, view the colored line through the center of the cartridge; instead, the line can only be seen through less than half of the right side of the cartridge.

Before turning to extrinsic evidence and the prosecution history of the patent, this Court must first address a problematic aspect of the above-quoted language. This claim describes a cylindrical cartridge 8 that is substantially transparent in the transverse direction so that a user may see from one "side" of the cartridge to the other. Since this description apparently refers to a "circular cylinder"--that is, to a cylinder whose bases are circles, Webster's New World Dictionary of Mathematics 31 (1989)--it is most helpful to think about this description in terms of circles.

Unfortunately, however, a circle has no "sides." Unlike other geometrical figures which are defined in terms of the number of sides they possess 9 and their relation to each other, 10 a circle is defined as "a plane curve consisting of all points at a given distance from a given point." Webster's New World Dictionary of Mathematics 30 (1989). Moreover, the term "side" is defined as "the bounding line of a geometrical figure," Webster's Third New International Dictionary 2111 (unabridged 1976), and in ordinary Euclidean geometry a "line" is conceived of as being straight and of unlimited extent. Webster's New World Dictionary of Mathematics, 156-57 (1989). Therefore, the claim's reference to seeing "from one side of the cartridge to the other" is less helpful than might initially be supposed. 11 Accordingly, this Court's analysis will focus instead upon the meaning of the phrase "substantially transparent in the transverse direction."

9 A polygon is defined as "a closed path of connecting line segments AB, BC,... [which are termed] the sides of the polygon." Webster's New World Dictionary of Mathematics 200 (1989). Polygons are named according to the number of their sides: a triangle has three sides; a quadrilateral, four; a pentagon, five, and so on. Id.

10 For example, quadrilaterals, which are four-sided polygons, are classified by the parallelism of their sides: "the figure is a trapezium, trapezoid, or parallelogram depending upon whether no, one, or two pairs of opposite sides are parallel, respectively. A rectangle is a parallelogram with all angles equal, and a square is a rectangle with all sides equal." Webster's
Having demonstrated that the term "side" is a misnomer when used in reference to a circular cylinder, this Court will nevertheless observe that the expression "from one side to the other" clearly describes a point opposite the point of origin. Therefore, had this Court relied upon this expression to construe the claim, it would have concluded that this phrase indicates that a user must be able to see through the center of the cartridge to the opposite point of the cartridge, as opposed to merely being able to view a point which is an infinitesimal distance away.

Relying upon its authority to look to extrinsic evidence for assistance in construing the meaning of this claim, this Court will turn first to the dictionary. The definition of "transverse" is "extended or lying across or in a crosswise direction." Webster's Third New International Dictionary 2431 (unabridged 1976). The term "across" is defined as "to or on the opposite side." Id. at 20. Although this might appear merely to bring this Court to its earlier observation that a cylindrical cartridge does not have sides, the term "opposite" is a useful addition, suggesting that a user must see through the central longitudinal axis of the cartridge in order to view the opposite point (rather than side) of the cartridge, exactly one hundred and eighty degrees on the circle from the initial point.

The term "central longitudinal axis" is arguably a redundancy, as the term "axis" refers to "a straight line about which a body or three-dimensional figure rotates or may be supposed to rotate." Webster's Third New International Dictionary 153 (unabridged 1976). Presumably, therefore, the Defendant's cylindrical cartridge has only one longitudinal axis, located in the center of the cartridge. However, given that the parties have disputed this point, this Court will employ the term "central longitudinal axis" for purposes of clarity.

Of course, given that the object discussed here is a three-dimensional cylinder rather than a two-dimensional circle, the user need not confine himself to looking directly across the cartridge in order to view "in the transverse direction," but may also look toward any point directly above or below the opposite point on the cartridge. The common denominator is that the user must look through the central longitudinal axis in order to view any of these points.

This initial conclusion is buttressed by a further observation. Given that a circle (and thus a cylindrical cartridge) has no sides, there are only two possible ways to construe the phrase "in the transverse direction": either it describes a direction extending toward the opposite point of the cartridge, exactly one hundred and eighty degrees on the circle from the initial point, or it describes a direction extending toward any point of the cartridge, including a point just an infinitesimal distance away. The first construction appears to be the most logical choice, for two reasons.

First, the phrase "in the transverse direction" appears to refer to a particular, measurable direction, as opposed to any of numerous possible directions which would intersect any point of the cartridge, including points just an infinitesimal distance away. If this were not the case, the patent could have simply used the term "in any direction and for any distance."

Second, the latter construction, somewhat incongruously, would allow the Defendant's patent to encompass any cartridge which is substantially non-transparent, but which has a viewing window large enough to permit the user to see "through" the cartridge to any other point on the cartridge. This construction is belied by both the prosecution history and the claim itself. As discussed earlier, the Patent Examiner initially rejected Claim 1 for obviousness but later indicated that it "may be allowable if the motivation and the advantage of placing transparent caulk in a transparent container is set forth in the claim other than for viewing contents purposes." Defendant Sashco amended its claim accordingly to reflect the following advantages realized by its product:

the substrate may be viewed through the combination of the housing and the caulking material placed therein so that the appearance of the substrate as affected by the caulking material may be seen prior to application of the caulking material and [] the position of the piston member may be viewed as the caulking material is dispensed from the housing.
'458 patent, Claim 1. These advantages--allowing the substrate, as it will be affected by the caulking material, to be viewed prior to applying that caulking material, and viewing the piston as the material is applied--would appear to require more transparency than that which can be provided by a viewing window, which may or may not allow one to directly "line up" the cartridge with the surface of the item to which the caulking compound is to be applied, so as to enable one to see how that surface will look once that compound is so applied. In any event, given the prosecution history described above, there must be some appreciable difference between Defendant Sashco's product and a product which merely allows the user to view the contents. Accordingly, this Court will not construe this Claim as encompassing all substantially non-transparent cartridges which have a large viewing window.

For the foregoing reasons, this Court will interpret the phrase "in the transverse direction" to mean toward the opposite point of the cartridge (i.e. one-hundred and eighty degrees from the initial point), and toward all points which are directly above and below that point. This construction necessarily limits the patent to situations wherein the user may view directly through the central longitudinal axis of the cartridge.

--- Footnotes ---

14 This Court notes here that it has reviewed the deposition testimony of Plaintiff's expert, Richard Killworth, which was cited by the Defendant in its Motion (Doc. # 61) and which discusses the interpretation of both of the patents at issue here. This Court concludes that this testimony does not refute or undermine the Plaintiff's arguments.

--- End Footnotes ---

There is another reason why this construction of the patent's claim must be the correct one. The claim emphasizes that the "substrate may be viewed through the combination of the housing and the caulking material placed therein so that the appearance of the substrate as affected by the caulking material may be seen prior to application of the caulking material." This result can only be achieved if a user is able to see the area directly beneath and below the nozzle (which extends from the very center of the top of the cartridge), away from the piston, because this is the area to which the caulking material will be applied. As a practical matter, therefore, a user who wishes to view the substrate through the cartridge (as opposed to looking directly at the substrate surface by angling his or her head), will position himself or herself at the opposite end of the cartridge, so that he or she is "lined up" with the nozzle. From this position, he or she must look through the central longitudinal axis of the cartridge so as to view the substrate to which the caulking material will be applied. Importantly, a mere ability to see through any other portion of the cartridge--which, of necessity, would put the viewer's line of sight at an angle with the substrate and the piston--would not allow one to view the area directly below the nozzle, which is the area of the substrate to which the caulking material will be applied. Thus, the claim's asserted function can only be realized if the user is able to view directly through the central longitudinal axis of the cartridge.

As a final matter, this Court notes that the claim's requirement that the "position of the piston member may be viewed as the caulking material is dispensed from the housing" can be fairly interpreted as supporting its construction of the patent's claim. In regard to this function, the crucial issue is whether a partial view of the edge of the piston (as is provided by the Plaintiff's cartridge, due to the existence of an opaque mask which obscures 58% of the cylinder) is sufficient to fulfill this function, or whether a view of more than fifty percent of the piston member--which necessarily is only achievable if any existing mask obscures less than 50% of the cylinder, so that a user can view directly through the central longitudinal axis of the cartridge--is required.

The answer to this issue would appear to depend upon the physical configuration of the piston member. For example, if the piston member is merely a flat base, a failure to exert pressure directly in the center of the piston might cause the piston member to slide unevenly, thus requiring a view of more than half of the piston member in order to determine the precise extent of the unevenness and the resulting position of the piston member. If, however, the piston member is "cup-shaped in configuration so that it has a flat base plate [] which bears against caulking material," as is described in the Defendant's preferred embodiment, then the piston member should slide evenly, thereby allowing a user to be certain of the precise position of the entire piston member even if he or she has only a partial view of said piston.

Accordingly, this Court must inquire as to whether the Defendant's patent is necessarily limited to piston members which have cup-shaped configurations. In this regard, the Court notes that the only part of the patent which describes the piston member as having a "cup-shaped configuration" is the patent's description of the preferred embodiment. However, language
in the patent which immediately precedes the claim clearly reflects the Defendant's intent not to limit its patent to the description of its preferred embodiment:

The present invention has been described with some degree of particularity directed to the preferred embodiment of the present invention. It should be appreciated, though, that the present invention is defined by the following claims construed in light of the prior art so that modifications or changes may be made to the preferred embodiment of the present invention without departing from the inventive concepts contained herein.

Moreover, the Federal Circuit has "cautioned against limiting the claimed invention to preferred embodiments or specific examples in the specification." Texas Instr. v. United States Int'l Trade Comm'n, 805 F.2d 1558, 1563 (Fed. Cir. 1986); accord Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1988) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations"), cert. denied, 490 U.S. 1068, 104 L. Ed. 2d 634, 109 S. Ct. 2069 (1989). Therefore, this Court will not construe the Defendant's patent as being limited to piston members with cup-shaped configurations. Instead, this Court will construe the patent as encompassing other possible configurations of the piston member, including a flat base which may slide unevenly if pressure is not applied to the direct center of the piston member. In such a case, the user's need to view more than half of the piston member in order to determine the precise extent of the unevenness and the resulting position of the piston member, supports this Court's construction of the Defendant's claim to be limited to situations wherein the user may view directly through the central longitudinal axis of the cartridge.

B. Construction of Clauses (b) and (d):

Clause (b): "said upper wall portion being constructed for substantially uniform airflow therethrough over substantially the entire plan surface area of said upper wall portion." Clause (d): "said secondary wall means being constructed for substantially uniform passage of air therethrough over substantially the entire plan surface area of said secondary wall means."

The '767 patent claims an air flotation, ventilated mattress apparatus comprising, among other things, an upper wall portion and a secondary wall means that are "constructed for substantially uniform passage of air therethrough over substantially the entire plan surface area of said secondary wall means." The parties agree that when the claim language refers to "substantially uniform passage of air," it means airflow which is substantially steady, constant or continuous, as opposed to fluctuating, intermittent or alternating over time. See Plaintiff's Ex. 1; Defendants' Ex. 408 ("person of ordinary skill in the art would read 'uniform airflow' to mean air flows at essentially the same rate. . . ."). They disagree about where the patent claims the substantially steady air flow will occur. Plaintiff alleges that although the patent claims "substantially uniform airflow . . . over substantially the entire plan surface area," the claim does not specify the spatial location through or at which air will flow. Rather, according to plaintiff, it means that air flow will be constant "wherever air flows." According to defendants, the requirement for "substantially uniform airflow . . . over substantially the entire plan surface area" means that at substantially all locations on the plan surface, air flows at essentially the same rate.

Footnotes:

4 The patent claims for the upper wall portion and the secondary wall means are substantially identical, except that the upper wall portion claims "substantially uniform airflow" and the claim regarding the secondary wall means is for "substantially uniform passage of air." The difference is not material to any issue before the Court.

5 Among other problems with plaintiff's argument, it is hopelessly circular. As noted, plaintiff alleges that the claim language ("over substantially the entire plan surface area") does not specify the spatial location through or at which air will flow, but merely means that air flow will be constant "wherever air flows," and that "this is true" over substantially the entire plan surface. What plaintiff really argues, though it is less than candid in framing the issue, is that the Court should altogether ignore the claim requirement that air flow at a substantially uniform rate "over substantially the entire plan surface area."

6 Although defendants' motion refers to "are" flow, it is clear from defendants' supporting memorandum that the intended word is "air."
Plaintiff argues that if the Court were to adopt defendants' proffered construction, the invention would be impossible to make because when a patient lays on the mattress, air cannot flow at the points of contact. Plaintiff's interpretation ignores the fact that the "uniform air flow" clauses continue with "therethrough over substantially the entire plan surface area of [said secondary wall means and upper wall portion]. The claim demands that air flow through all locations on the surfaces. Defendants' construction would seem to give the proper meaning in context. Further, as defendants point out, the claim sets out a mattress with an "air permeable wall." Because the patent does not suggest that this permeability varies substantially from place to place, it is logical to conclude that the patent intended air flow which is uniform in space. This conclusion is supported by the fact that in distinguishing Schild, plaintiff mentioned that Schild included a non-permeable upper wall means. Further, the patent specification mentions many times the need to ventilate the patient's skin at all adjacent areas.

The Court finds that the phrase "substantially uniform airflow therethrough over substantially the entire plan surface area" has a plain meaning in light of the '767 claims, the '767 specification, and the '767 prosecution history. A person of ordinary skill in the art of air bed engineering would read "substantially uniform airflow" to mean airflow that does not substantially fluctuate over time. When added to the words "over substantially the entire plan surface," the claim requires that air flow at substantially the same rate at substantially all locations on the surface.

The district court construed clause (b) - an "upper wall portion being constructed for substantially uniform airflow therethrough over substantially the entire plan surface area of said upper wall portion" - and clause (d) - "secondary wall means being constructed for substantially uniform passage of air therethrough over substantially the entire plan surface area of said secondary wall means" - to require "air flow at substantially the same rate at substantially all locations on the surface." KCJ I, 30 F. Supp. 2d at 1326. The district court thus required uniformity of airflow both temporally and spatially.

This court thus examines whether clauses (b) and (d) require an airflow uniform both in time and space. During the trial court's proceedings, "the parties agreed that when the claim language refers to 'substantially uniform passage of air,' it means airflow which is substantially steady, constant or continuous, as opposed to fluctuating intermittent or alternating over time. . . . [However,] they disagreed about where the patent claims the substantially steady air flow will occur." Id. at 1325-26. On appeal, KCJ maintains that the "continuous passage of air" requires uniform airflow only in a temporal sense. Specifically, KCJ asserts: "As used in clauses (b) and (d) of claim 1 of the '767 patent, 'substantially uniform airflow over substantially the entire plan surface area' means that wherever air comes through anywhere over the surface area, it will flow at a substantially uniform or constant rate over time." This court, however, agrees with the district court that claim 1 requires uniformity in space as well as time.

First, the claim language itself requires spatial uniformity. Clause (b) requires "uniform airflow therethrough over substantially the entire plan surface area." "767 patent, col. 6, ll. 12-13 (emphasis added). Similarly, clause (d) requires "uniform passage of air therethrough over substantially the entire plan surface area." Id. at col. 6, ll. 19-20 (emphasis added). As the district court aptly noted, "the claim demands that air flow through all locations on the surfaces." KCJ I, 30 F. Supp. 2d at 1326. To limit uniformity to temporal aspects would render these limitations meaningless.

The written description of the '767 patent reinforces the essential nature of spatial uniformity. The present invention is an
"air flotation mattress . . . supporting a recumbent patient entirely by means of a throttled flow of pressurized air which also ventilates and cools all adjacent areas of the patient's skin." '767 patent, col. 2, ll. 41-45. To enable the mattress to "continuously ventilate all areas of the skin adjacent the mattress," there must be airflow over the entire plan surface area as the claim recites. Id. at col. 3, ll. 4-5. In fact, the written description explains:

Pressurized air passes evenly through virtually the entire plan surface area of the top wall 26. As a consequence, such air also serves to inflate the upper compartment 40 between top wall 26 and secondary wall 36. Such pressurized air then flows evenly through the suede or leather secondary wall 36; here again, this airflow is substantially even over substantially the entire plan surface area of the wall 36.

Id. at col. 5, ll. 18-25 (emphasis added). Unless the air mattress has uniform airflow over substantially the entire plan surface area, a patient lying on the secondary wall would not be "supported entirely by the inflatable compartment and chamber without the necessity of spines or other internal, non-inflatable solid support structure within or forming a part of the mattress apparatus." Id. at col. 2, ll. 63-66 (emphasis added).

The record of the administrative proceedings before the PTO supports this interpretation of claim 1. In seeking allowance of the pending claims, the patentee added clauses (b) and (d) to claim 1 and remarked:

In no way does the alternating pad of the Schild et al. reference supply positive pressure air throughout the entirety of the chamber during all operations of the mattress. . . . Moreover, Gammons et al. does not provide means for continuously maintaining positive air pressure conditions throughout the entirety of the lower chamber during the entirety of the operation of the mattress apparatus.

J.A. at 138-39 (emphasis added). The express statements of the patentee clarify that the airflow limitations require both a temporal and spatial uniformity. In sum, the prosecution history also supports the district court's interpretation of clauses (b) and (d). To read the claim otherwise would ignore express language of the claim requiring airflow "over substantially the entire plan surface area." '767 patent, col. 6, ll. 14-15.

The district court determined that clauses (b) and (d), when properly construed, do not read on Kinetic's accused mattresses. Literal infringement of a claim occurs when every limitation recited in the claim appears in the accused device, i.e., when "the properly construed claim reads on the accused device exactly." Amhil Enters., Ltd. v. Wawa, Inc., 81 F.3d 1554, 1562, 38 U.S.P.Q.2D (BNA) 1471, 1476 (Fed. Cir. 1996). The district court construed clauses (b) and (d) to require uniform airflow in time and over the entire plan surface area. KCJ conceded that under the district court's construction, which this court upholds, "limitations of . . . Clause (b) are not met by any of the accused devices." KCJ II, 39 F. Supp. 2d at 1289 n.2. Accordingly, this court affirms the district court's grant of summary judgment of no literal infringement.

3. What is the Proper Construction of the Phrase "substantially uniform cross-section" in the '092 and '948 Patents?

Claim 1 of the '092 patent and claim 1 of the '948 patent contain the phrase "a die of substantially uniform cross-section." KXI contends the term "substantially" means "at least a 10% change in size." KXI contends that as applied to the claim, the phrase "substantially uniform cross-section" means "the die should not change in diameter by more than 10%." Culligan contends the phrase "substantially uniform cross-section" in the '092 and '948 patents means the internal cross-section of the die must vary less than about 0.010 inch along the length of the die.

The contested phrase reads: "a substantially uniform cross-section, which cross-section is not substantially smaller than the cross-section of an inside diameter of the extruder barrel[]." KXI contends the word "substantially" in the phrase "substantially uniform cross-section" should be defined consistently with the term "substantially" in the phrase "not substantially smaller than the cross-section of an inside diameter of the extruder barrel[]."

KXI contends the phrase "not substantially smaller" is defined in the '092 and '948 patents' specifications. The relevant parts of the specifications read:
There are distinct limitations on the ability to compress the material into a die smaller than the extruder. However, it has been discovered that, if that is to be attempted . . . the ratio of the cross-sectional area of the die mouth to the extruder output are not should be less than approximately 0.9.

KXI interprets this to mean that the cross-section of the die can be 10% smaller than the size of the cross-section of the barrel. KXI contends the term "substantially" used both in "substantially smaller" and "substantially uniform cross-section" means up to a 10% change in size. Accordingly, KXI argues "a substantially uniform cross-section" means the die's diameter should not change by 10%. KXI cites a recent federal district court case in support of the proposition that "since the term 'substantially' is used twice in the claim, it cannot have more than one meaning." Atmel v. Information Storage Devices, Inc., 997 F. Supp. 1210, 1215 (N.D. Cal. 1997).

Culligan responds that there is no reason to give the term "substantially" the same meaning in both phrases, as the term "substantially" is used fourteen times in claim 1 of the '092 patent and claim 1 of the '948 patent. Culligan also argues that Atmel does not support KXI's legal proposition. Instead, Culligan contends that Atmel holds that "identical or 'indisputably interchangeable' claim terms in patents that share a common ancestry should be construed consistently." Id. at 1215.

The court agrees with Culligan that there is no reason to construe "substantially" as having the same meaning in both phrases. The court finds the term "substantially" is used throughout claim 1 of both patents, and there is no indication that the patentee gave the term a uniform meaning.

Culligan contends the term "substantially uniform" was defined during the prosecution of the '948 patent to mean less than 0.010 inch. In both the October 2, 1992 Amendment and Request for Reconsideration and the March 10, 1993 Amendment and Request for Reconsideration, the '948 patentee distinguished the extruder disclosed in the Zavasnik patent based upon the "increasing cross-sectional area" of the forming die. The patentee stated: "the forming die in Zavasnik must be of increasing cross-sectional area--see column 2, line 59-65 and column 4, lines 22-24. In contrast, the extrusion die of the claimed invention is of substantially uniform cross-section."

The Zavasnik patent at column 2, lines 59-65 reads:

The cross-sectional dimensions of the forming die 26 at its entrance . . . should be somewhat larger than that of the extruder crosshead die opening indicated at 52, e.g., about 0.01 to about 0.02 inch larger. The increase in die opening size will accommodate any expansion on the part of the plasticized thermoplastic material.

Culligan argues that when the patentee cited this section of the Zavasnik specification, he told the examiner that the Zavasnik extruder did not have a "substantially uniform" die because there is a variance of at least 0.010 inch. Culligan contends "by the time the patentee got its claims allowed, because this overcame the examiner's rejection, the patentee obviously believed that something which varied by 0.010 inch was not 'substantially uniform' in cross-section."

KXI responds that this Zavasnik reference is irrelevant because it does not describe a die which increases in cross-section over its length. KXI contends there are two dies disclosed in the Zavasnik patent; an extrusion die (11) and a forming die (26), and that these two dies are separated by an air gap. According to KXI, the Zavasnik patent at column 2, lines 59-64 requires that the opening of the forming die (26) be larger than the opening of extrusion die (11), to "receive' the extrudate after it crosses the air gap . . . ." Therefore, KXI argues, 0.010 inch is not applicable to the change in diameter across the die.

The court agrees with KXI that the Zavasnik patent does not refer to an increasing cross-sectional diameter along the forming die, but to increase in the diameter of the opening of forming die (26) with respect to the extruder die (11). The court finds, however, that the patentee presented the 0.010 inch figure by reference during the prosecution of the '948 patent to distinguish the Zavasnik patent's prior art, and to represent the rate of variance in the die's cross section that is not "substantially uniform." Accordingly, the court construes the phrase "substantially uniform cross-section" in the '948 patent to mean less than a 0.010 inch variance in diameter along the length of the die.

The court also relies on the '948 patent's prosecution history as extrinsic evidence of the meaning of the phrase "substantially uniform cross-section" in the '092 patent. The court finds the term "substantially uniform cross-section" should be defined consistently in both patents as both patents use the exact same phrase to describe the same structure, and
the '948 patent was originally filed as a continuation-in-part application of the application which led to the '092 patent. Accordingly, the court also construes the phrase "substantially uniform cross-section" in the '092 patent to mean less than a 0.010 inch variance in diameter along the length of the die.

3970

3) "substantially uniform cross-sectional area"

Plaintiff argues that the court should decide whether an intake passageway has a "substantially uniform cross-sectional area" by reference to its cross-sectional area size and its cross-sectional area shape. Defendant suggests that an intake passageway has a substantially uniform cross-sectional area if it has largely or approximately the same cross-sectional area across its length. I conclude that an intake passageway has a substantially uniform cross-sectional area if it has approximately the same cross-sectional area across its length.

The '502 patent does not distinguish between the cross-sectional area "size" and "shape," either explicitly or implicitly. The ordinary meaning of the word cross-section is "a surface or shape that is or would be exposed by making a straight cut through something, especially at right angles to the axis." New Oxford American Dictionary 409 (2001). The ordinary meaning of "area" is "a measure of the size of a two-dimensional surface, or of a region on such a surface." McGraw-Hill Dictionary of Scientific and Technical Terms 113 (6th ed. 2003). Thus, the cross-sectional area of an intake passageway is the measurement of the surface that would be exposed by making a straight cut through the intake passageway. Therefore, an intake passageway has a substantially uniform cross-sectional area if it has approximately the same cross-sectional area across its length.

3971

1. What is the Proper Construction of the Phrase "substantially uniform mixture" in the '092 patent and "substantially uniform particulate mixture" in the '948 patent?

Claim 1 of the '092 patent contains the phrase "particles in a substantially uniform mixture" to describe the feed mixture composed of primary particles and binder particles. Claim 1 of the '948 patent contains the phrase "substantially uniform particulate mixture" to describe the feed mixture composed of primary particles and binder particles. KXI contends the words should be given their ordinary meaning, and that these phrases refer to a largely--but not necessarily wholly--even distribution of particles. KXI contends there are no other mixing requirements and no special methods of mixing required. The test for proper mixing, according to KXI, is stated in the '092 patent's specification at column 8, lines 7-14 and the '948 patent's specification at column 8, lines 13-19:

An experienced operator can also readily notice a reduction in the flow characteristics of the powder mixture that indicates the formation of the desired bonds between particles. Samples smeared on a black surface show no residual binder aggregates which would be indicated by the presence of small white streaks.

Culligan argues that the specifications of the '092 and '948 patents define the terms "substantially uniform mixture" and "substantially uniform particulate mixture" in a special way. According to Culligan, "substantially uniform" is a limitation requiring the formation of stable attachments between the primary particles and binder particles. Culligan argues that the claim requires vigorous mixing until stable "prebonds" or "microaggregates" are formed between the primary particles and binder particles throughout the mixture. Culligan points to provisions of the specifications reading:

Correct methods of mixing produce a material composed of microaggregates of primary particles and binder particles . . . . Poorly mixed materials, or use of binder or primary particles lacking the ability to form stable "prebonds" results in mixtures where binder and primary particles separate, or where primary particles of widely varying density or morphology separate because stable aggregates have not been formed. It is these stable aggregates, formed during mixing that allow this process to bond particles that cannot normally be maintained in a stable mixture. It appears that, as a rule, the process is generally not workable with poorly mixed materials or with materials in which the binder particles have not
become attached to the primary particles during the mixing step.

Culligan argues that here the '092 and '948 patents' specifications tell a person knowledgeable in the art that they must mix the primary and binder particles in a certain way to practice the invention; so as to create stable "prebonds" or "microaggregates."

The Federal Circuit has held that "the specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Culligan argues that the specifications of the '948 and '092 patents expressly defines the phrase "substantially uniform." KXI argues in response that it is only appropriate to give a term a special meaning where "the special definition of the term is clearly stated in the patent specification or file history." Id. at 1582.

The court agrees with KXI that the patentee did not give special meaning to the phrase "substantially uniform mixture" or "substantially uniform particulate mixture" in the '092 and '948 patent's specifications. The court construes the words "substantially uniform particulate mixture" and "substantially uniform mixture" according to their ordinary meaning. Accordingly, the court construes the phrases "substantially uniform mixture" and "substantially uniform particulate mixture" as meaning a largely—but not wholly—even distribution of particles.

H. "Substantially Uniform Structure of Flexible Cells"

The words "substantially uniform structure of flexible cells" are used in claim 28 of the '303 Patent. Medinol argues that this term refers to "a stent structure that has a largely repeating distribution of flexible cells that have nearly the same structure." Guidant contends it means "all of the cells of the stent have substantially the same structure." The phrase "uniform structure of flexible cells" was construed by the Cordis court for purposes of claim 12 of the '303 Patent. That court determined that the phrase means "the flexible connected cells of claim 6 have the same structure." This construction draws from the patent specification, where the patentee states, with respect to Figure 8, that "all spaces are of the same size, i.e., the stent is comprised of a plurality of spaces or cells 50 defining a uniform cellular structure." The parties agree that this definition is the foundation upon which the meaning of the word "substantially," denoting approximation, must be built. Given that "uniform structure of flexible cells" means "the flexible connected cells have the same structure," it is clear that the word "uniform" is taken to modify the structure, rather than the overall arrangement, of the flexible connected cells. The word "substantial," then, also modifies the structure of the cells - i.e., as Guidant indicates, the phrase "substantially uniform structure of flexible cells" means that all of the flexible connected cells have approximately the same structure.
context, denotes approximation.

120 Medinol's primary objection to Guidant's proposed construction of this term relates to the use of the word "including" in the claim language. Specifically, the claim reads, in relevant part: "An expandable stent, including: a plurality of connected cells having a longitudinal axis defining a substantially uniform structure of flexible cells having a longitudinal axis and a circumferential axis substantially perpendicular to said longitudinal axis . . . ." '303 Patent, col. 10, ll. 14-19 (emphasis added). Defining the word "including" to mean less than all, Medinol asserts that, according to the specification, not all of the cells can have substantially the same structure. But Medinol has explicitly made statements to the contrary, arguing that notwithstanding the patentee's use of the word "including" in claim 12 of the '303 Patent, the term "uniform structure of flexible cells," refers to "all cells of the stent." See Medinol's Brief in Support of Its Appeal in the Cordis Action (filed under seal), Ex. 48 to 9/9/04 Affirmation of Robert F. Shaffer, counsel for Guidant, at 37-39. Accordingly, Medinol's argument for a restrictive reading of "including" fails.

The district court construed the "substantially uniform thickness" limitation to require that the thickness of the stent's wall surface not vary by 0.001 inch or more. Cordis contends that the district court erred by imposing the numerical restriction of 0.001 inch with respect to that limitation.

The patents do not set out any numerical standard by which to determine whether the thickness of the wall surface is "substantially uniform." The term "substantially," as used in this context, denotes approximation. See Epcon Gas Sys., Inc. v. Bauer Compressors, Inc., 279 F.3d 1022, 1031 (Fed. Cir. 2002). Thus, the walls must be of largely or approximately uniform thickness. Moreover, the written descriptions of the two patents state only that the expansion of the tubular member is uniform "along the length of tubular member 71" in part because of the uniform thickness of the wall surface, specifically pointing to the "same uniform thickness" of the connecting members 77, the elongate members 75, and members 78 and 79. '762 patent, col. 7, ll. 21-33; '984 patent, col. 6, ll. 47-54. Accordingly, the "substantially uniform" limitation also requires that the thickness of the wall surface be sufficiently uniform along its length and between members to allow uniform expansion of the stent. The question presented here is whether there is anything in the prosecution history of either patent that justifies giving the "substantially uniform thickness" limitation an even narrower construction.

In its discussion of the Ersek patent during reexamination of the '762 patent, Cordis argued that, according to the Antonsson affidavit, the Ersek device is not smooth and that "the wall thickness [of an Ersek model] varied at different points" and "ranged from a minimum thickness of 0.0035 inches to a maximum thickness of 0.0045 inches." Cordis noted that the Antonsson affidavit addresses a model of an Ersek device in its expanded configuration, but that the thickness of the Ersek device is not substantially uniform in either its unexpanded or expanded configuration. Based on those statements, the district court construed the "substantially uniform thickness" limitation to require variations in wall surface thickness of less than 0.001 inch.

The commentary on Dr. Antonsson's measurement of a model, however, does not constitute a "clear and unmistakable" disclaimer, see Omega Eng'g, slip. op. at 17, excluding stents that vary in thickness by 0.001 inch or more. Cordis did not suggest that the variation of 0.001 inch was the basis for distinguishing its invention from Ersek or that Cordis's claimed stents vary by less than 0.001 inch in thickness. Rather, Cordis's basis for distinguishing Ersek appears to have been that Ersek's walls were at least twice as thick at the intersections of strands as along the strands themselves. The alleged disclaimer based on Dr. Antonsson's measurements in the reexamination proceedings was at best ambiguous. See IMS
Tech., Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1439 (Fed. Cir. 2000) ("In light of the ambiguity of the patentee's statements and the subject matter actually disclosed in the references, we cannot say that the patentee clearly disavowed coverage of [the contested subject matter].").

In addressing Ersek, Cordis focused on the double thickness of the bridge portions of Ersek's walls. For example, in its response to the examiner's reexamination rejection of claims in light of Ersek, Cordis stated:

As shown . . . in Ersek Figure 5 . . . the wall of [the Ersek device] is of varying thickness because the strands of the sleeve have twisted out of the plane of the starting material. Moreover, the bonds or bridges at the junctions of the strands protrude inwardly and outwardly of the plane of the starting material, and as a result the Ersek sleeve 16 has a non-uniform wall of varying thickness.

Since the bonds or bridges extend generally radially outwardly of the sleeve 16, the sleeve has 100% variance in thickness as compared to the thickness of the starting material in the areas of the bonds or bridges.

Figure 5 of the Ersek patent is shown herein:

[CENTER]

Cordis reiterated its contention that Ersek did not have a wall surface with a substantially uniform thickness in that submission:

Clearly, the Ersek sleeve cannot be fairly said to have a wall surface with "a substantially uniform thickness". The expanded metal Ersek sleeve has bridge portions that are several times as thick as the strands. . . . The strands extending between the bridge portions are twisted to have inwardly and outwardly projecting edges. This irregular and variable configuration is rough and is the antithesis of "substantially uniform thickness". The use of the term "substantially uniform" does not exclude some variations in dimension between the inner and outer surfaces of the wall. Even so, it is clear that Ersek's rough and irregular wall does not have substantially uniform thickness. Antonsson Affidavit, paragraph 10.

At Cordis's request, Dr. George Andros submitted a declaration to the PTO as a part of the reexamination of the '762 patent. Dr. Andros stated that "the Ersek fixation sleeve does not have a substantially uniform wall thickness, nor is it thin walled. The expanded metal sleeve is twice as thick in some areas as in others, and the thickness of the wall varies throughout." Cordis thus focused on the double thickness of the bridge portions of the Ersek device, not on Dr. Antonsson's assertion that the thickness of the Ersek device varied by up to 0.001 inch along the strands.

Based on our review of the prosecution history, we conclude that a reasonable reading of the patentee's statements would not lead one to conclude that variations greater than 0.001 inch fall outside the scope of the '762 patent. Because there is no clear and unmistakable disclaimer of any variation in thickness of 0.001 inch or more, the district court erred in imposing that numerical restriction on the "substantially uniform thickness" limitation. The discussion of the Ersek patent does, however, support the conclusion that the owner of the '762 patent disclaimed coverage of any device with a variation of at least 100 percent. In any event, quite apart from any disclaimer, a wall that varies in thickness by as much as 100 percent cannot be said to be of "substantially uniform thickness" either literally or by equivalents.

3. "Substantially uniform thickness."

Consistent with this court's previous construction 27 and the Federal Circuit's review of that construction, 28 "substantially uniform thickness" is construed to mean "the wall of the tubular member must be of largely or approximately uniform thickness. A wall that varies in thickness by as much as 100 percent cannot be said to be of substantially uniform thickness."
This court does not view the Federal Circuit's 2003 opinion as reversing its original construction of "substantially uniform thickness," but instead clarifying the scope of that construction. Cordis Corp. v. Medtronic, Inc., 339 F.3d 1352, 1360-62 (Fed. Cir. 2003). Thus, this court does not agree with BSC that the Federal Circuit's opinion added to the limitation that the stent must allow for "uniform expansion."

The second claim limitation upon which the parties focus is that the forward wall must have a "substantially uniform thickness inside the perimeter wall." Interpretation of this claim phrase turns on the meaning of the modifying term "substantially." The term "substantially" does not mean "essentially" or "exactly" but is a relative term which the Court interprets in context. See, e.g., John Blue Co. v. Dempster Mill Mfg., Co., 172 F. Supp. 23, 27 (D. Neb. 1958). In the context of machine-tooled metal, "where tolerances are measured in by a micrometer, "substantially uniform thickness" . . . would call for differentials of no more than perhaps 0.001 [inches]. But in dealing with (say) the topography of mountain ranges, 'substantially uniform' height . . . could permit differences of hundreds of feet or more." O'Hara Mfg. Ltd. v. Eli Lilly, 1986 U.S. Dist. LEXIS 22546, at *40 n.8, No. 85 C 3979 (N.D. Ill. July 18, 1986). In the production of ice cream, by further contrast, a claim term requiring production temperatures "substantially" in a certain range is still satisfied by temperatures falling a degree or two outside of that range. See Dippin' Dots v. Mosey, 1997 U.S. Dist. LEXIS 20896, at *13-14, No. 3:96-CV-1969-X (N.D. Tex. Mar. 31, 1997). Implicit in these contrasting examples is the principle that the function of the thing at issue is an important consideration in defining this term. See John Blue Co., 172 F. Supp. at 27. Thus, "a thing is substantially the same as another if it performs the substantially the same function in substantially the same way to obtain the same result." Id.

The context of the term "substantially" in this case is investment cast metal. It is undisputed on the summary judgment record, that the standard tolerance for investment casting is +/-0.005 inches or +/-0.5%. Also instructive (present in Claim 12 but absent from Claim 15) is the phrase immediately following the claim phrase "substantially uniform thickness." In Claim 12, the subsequent phrase explains that the purpose of the uniform wall is to "reduce club head weight." Col. 11, lines 21-2. Reduced club head weight allows larger a club face and increases the radius of gyration, which are both focuses of the '941 Patent. This purpose supports the conclusion that substantially uniform in this context allows thickness deviations at or near the standard commercial tolerance.

Although this construction of "substantially uniform thickness" excludes some of the preferred embodiments from claims that contain this limitation, it does not exclude these embodiments from every claim in the '941 patent. In fact, the claims that specifically discuss the reinforcing matrix covered by a plastic face wall do not contain the "substantially uniform thickness" limitation. See, e.g., Claim 1, Col. 9, lines 12-25. Thus, despite some of the drawings, exceptionally wide variances in wall thickness cannot be encompassed within this limitation. Such an interpretation would impermissibly allow a drawing to contradict the plain language of the claim and render the phrase nonsensical. See, e.g., Raleigh v. Tandy Corp., 1997 U.S. Dist. LEXIS 22130, *20, No C-95-2332-MHP (N.D. Cal. Jan. 9, 1997) ("the specification may help define the terms of the claims, but the claim language is not to be contradicted by the drawings or the description of the preferred embodiments").
Here, we agree with Dana that the district court erred in construing the limitation "substantially uniform wall thickness" to mean a "wall thickness that does not vary more than the wall variation in the tube wall before swaging." We hold that "substantially uniform wall thickness" is properly construed to mean that the wall of the tube is largely or approximately uniform in thickness, but may vary at least as much as the wall thickness varied prior to swaging plus the variation in wall thickness that necessarily results from swaging the tube in accordance with the claimed invention of the '093 and '042 patents.

Looking first to the claim language itself, we are persuaded by Dana's argument that the limitation "substantially uniform wall thickness" must allow for variation in wall thickness greater than the pre-swaging variation in order to give meaning to the term "substantially." The pre-swaging manufacturing tolerance is a manufacturing reality that would have to be encompassed within the claim even if the modifier "substantially" was not used; otherwise, no real-world embodiment, including the patentee's own embodiment, could fall within the scope of the claim. The use of the modifier "substantially" signals that the claim drafter intended the scope of the claims of the patents-in-suit to allow for some variation greater than that variation that necessarily exists in any driveshaft claims due to simple manufacturing realities.

The term "substantially" is commonly used by claim drafters to indicate approximation. See Cordis Corp. v. Medtronic AVE Inc., 339 F.3d 1352, 1360 (Fed. Cir. 2003) ("The patents do not set out any numerical standard by which to determine whether the thickness of the wall surface is 'substantially uniform.' The term 'substantially,' as used in this context, denotes approximation. Thus, the walls must be of largely or approximately uniform thickness."); see also Deering Precision Instruments, LLC v. Vector Distribution Sys., Inc., 347 F.3d 1314, 1322 (Fed. Cir. 2003) ("Indeed, our cases recognize the dual ordinary meaning of this term as connoting a term of approximation or a term of magnitude."); Epcon Gas Sys., Inc. v. Bauer Compressors, Inc., 279 F.3d 1022, 1031 (Fed. Cir. 2002). We find that the term "substantially" was used in just such a manner in the claims of the patents-in-suit: "substantially uniform wall thickness" denotes a wall thickness with approximate uniformity.

Nothing in the specification confirms or conflicts with this construction. Indeed, the district court found, and the parties agree, that the written descriptions of the '093 and '042 patent are not helpful in construction of the disputed limitation because neither written description addresses wall thickness of the driveshaft tube, and the '042 patent's written description does not even describe the swaging process. We agree. With regard to the drawings in the patents-in-suit, we are persuaded by Dana's argument that the district court erred in relying on these drawings to limit the scope of the claims to only pre-swaging wall thickness variations. That the drawings of the patents delineate walls with parallel lines does not require that the claims be limited to tubes with wall thicknesses that are perfectly uniform except for pre-swaging manufacturing tolerances: the reduced size of the drawings (which are not drawn to scale to begin with) makes variation in wall thickness imperceptible. Moreover, even if the drawings were a reliable indicator of wall thickness variations in particular embodiments, that alone would not warrant limiting the claims to the wall thickness variation depicted therein.

We next turn to the prosecution histories of the patents-in-suit for guidance as to the construction of the limitation "substantially uniform wall thickness." As noted above, the district court found that, in the Petition to Make Special for the '093 patent, Dana characterized the prior art where a tube is swaged on a mandrel to control the inner diameter as having substantially uniform wall thickness, in contrast to an uncontrolled inner diameter produced by normal swaging, which was a non-uniform wall thickness. Order Regarding Claim Interpretation, 2003 U.S. Dist. LEXIS 25844 at *3-*4. Accordingly, the district court found that the "substantially uniform wall thickness" limitation was added to the claims to overcome prior art rejections based on normally swaged shafts (i.e., shafts swaged without an inner mandrel). Id. We disagree with the district court's interpretation of the prosecution history.

In the Petition to Make Special, the patentee argued:

U.S. Patent No. 3,854,316 to Wilson discloses a method of forming a hollow aluminum baseball bat having a substantially uniform thickness. Initially, a hollow cylindrical tube blank is extruded or drawn so as to have a constant diameter and thickness. Then, a longitudinal portion of the tube is placed on a mandrel having a constant outer diameter which corresponds to the inner diameter of the handle portion of the bat to be formed. Next, the handle portion of the tube is reduced, such as by swaging, to provide reduced outer and inner diameters and a substantially uniform thickness. During
this reduction step, the longitudinal relationship between the tube and the mandrel is maintained. . . . U.S. Patent No. 3,479,030 to Merola discloses a similar method. These patents clearly relate to a non-analogous field of art (baseball bats) relative to the claimed invention (driveshaft tubes for vehicles) and would not have been considered by a person having ordinary skill in the art.

We do not agree with the district court that this language constitutes a distinction between a shaft swaged with an inner mandrel (substantially uniform) and a shaft swaged without an inner mandrel (non-uniform). Indeed, the patentee characterized the entire bat as having a substantially uniform wall thickness. This is fully consistent with the Wilson reference itself, which teaches "[a] method of making a hollow metal ball bat having a wall thickness along the length thereof that is substantially uniform," regardless of whether the longitudinal portion was swaged with an inner mandrel. See U.S. Patent No. 3,854,316, Abstract (emphasis added). In addition, the remarks accompanying the patentee's amendment to the claims adding the disputed limitation indicate that the patentee sought to distinguish the patented invention on the grounds that the Shinohara reference cited by the examiner did "not disclose a driveshaft tube having a substantially uniform wall thickness throughout the central portion and the end portion." Thus, we cannot agree with the district court that the "substantially uniform wall thickness" limitation was added to distinguish normally-swaged shafts from shafts swaged with a mandrel.

Because the patent specification and prosecution history provide no specific numerical guidance as to the range encompassed by the term "substantially," and because we do not find convincing the scant expert testimony cited by the parties, we do not construe the limitation "substantially uniform wall thickness" as having any specific numerical range. Instead, we hold that "substantially uniform wall thickness" is properly construed to mean that the wall of the tube is largely or approximately uniform in thickness, but may vary at least as much as the wall thickness varied prior to swaging plus the variation in wall thickness that necessarily results from swaging a portion of the tube in accordance with the claimed invention of the '093 and '042 patents.

GO BACK

3977

I. "Substantially Uniformly Flexible (with Respect to Its Longitudinal Axis)"

"Substantially uniformly flexible (with respect to its longitudinal axis)" is referenced in claim 51 of the '018 Patent. 121 Medinol interprets this phrase to mean "the stent's flexibility is nearly the same as one moves along the longitudinal axis of the stent." 122 Guidant defines it as follows: "The structural elements of the cells provide longitudinal flexibility, such that the flexibility of the stent is substantially uniform only prior to expansion, as one moves along the longitudinal axis of the stent." 123

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

121 See '018 Patent, col. 13, ll. 4-6 ("A generally longitudinally extending tubular stent which is substantially uniformly flexible with respect to its longitudinal axis, said stent consisting essentially of . . . .").

122 Pl. Mem. at 28.

123 Def. Mem. at 26.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

The Cordis court construed two phrases similar to the term disputed here. First, "stent which is substantially uniformly flexible with respect to its longitudinal axis by the flexibility of its cells with respect to said axis," 124 was defined as: "The structural elements of the cells provide longitudinal flexibility such that the flexibility of the stent is substantially uniform as one moves along the longitudinal axis of the stent." 125 Second, "said loops adapted so that said stent prior to expansion is substantially uniformly flexible along its longitudinal axis," 126 was construed as: "The first loops and second loops must be oriented in different directions, one a generally vertical direction and one a generally horizontal or longitudinal direction, to provide substantially uniform flexibility to the unexpanded stent as one moves longitudinally along the stent." 127
The parties concur that the primary difference between their respective proposals is Guidant's assertion that the stent is substantially uniformly flexible only prior to expansion. 128 But inclusion of the phrase "only prior to expansion" in the construction is needlessly repetitive. When used elsewhere in the patent, the phrase "substantially uniformly flexible" is coupled with the words "prior to expansion of the stent," suggesting that including "prior to expansion of the stent" in the definition of "substantially uniformly flexible" would be unnecessarily duplicative. 129 Accordingly, the term is defined to mean: the flexibility of the stent is substantially uniform as one moves along the longitudinal axis of the stent.

The claims require the connector device to have a shallow guide member that extends along the inner side of at least one of the sidewalls of the housing and defines the upper and lower storage spaces of the housing. The claims further require that the storage spaces of the housing be "substantially uninterrupted by said shallow guide member.

We conclude that the district court's interpretation was correct. Berg's argument, that "storage space substantially uninterrupted" means that the guide member does not so interrupt the storage spaces as to prevent a hard disk drive package from fitting into both storage spaces, is not persuasive. The plain language of "substantially uninterrupted" means the lack of some type of structurally defined interruption; there is nothing in the claim itself which requires Berg's functional limitation.

The prosecution history also leads us to this construction. The Examiner required the addition of the whereby clause, "whereby said connector device is capable of accepting . . . a hard disk drive package that may occupy both storage spaces." 1204 Col. 8, Ins. 38-42. If the "substantially uninterrupted" language had the functional meaning ascribed by Berg, then the whereby clause would be superfluous.

Further, during prosecution Berg distinguished the Lai prior art reference on the basis of the complete interruption of storage
space by the Lai device's guide wall. Berg stated that Lai has a "common guide wall 34 [that] completely interrupts the area between consecutive storage spaces" and that "Lai does not teach or suggest Applicant's claimed use of 'shallow guide member' to define upper and lower storage spaces without substantially interrupting the overall storage space of the housing."

The only part of the Lai wall that completely interrupts the storage space is the part of the wall (34) that extends from the left side completely over to the right side of the storage space as the following figure shows:

[SEE FIGURE IN ORIGINAL]

Thus, during prosecution Berg defined a structure that extends completely from one side wall to the other side wall as completely interrupting the storage space. As a structure which completely interrupts must also substantially interrupt, a structure that extends completely from one side wall to the other side wall through the storage space must substantially interrupt the storage space.

We therefore conclude that the claims require a shallow guide member that extends longitudinally along the inner side of at least one of the sidewalls of said housing and defines the upper and lower storage spaces. The guide member cannot completely or substantially interrupt the storage space of the housing.

Summary judgment of no literal infringement is proper when no reasonable jury could find that every limitation recited in a properly construed claim is found in an accused device. See Cole. v. Kimberly-Clark Corp., 102 F.3d 524, 532, 41 U.S.P.Q.2D (BNA) 1001, 1007 (Fed. Cir. 1996).

As described above, all of the independent claims require that the storage space be substantially uninterrupted by a guide member. Inspection of the metal plate in the accused device shows that it constitutes a guide member as the arms of the metal plate form part of the guide member that extends longitudinally along the inner side of the guide walls and define the upper and lower storage spaces of the housing. The metal plate extends through the storage space from one side wall to the other thereby substantially interrupting the storage space.

Thus, because the Foxconn device contains a guide member which extends completely from one side wall to the other side wall and substantially interrupts the storage space of the housing, the device fails to meet the claim limitation "storage space substantially uninterrupted by [a] shallow guide member." Accordingly, no reasonable jury could find that Foxconn's device meets all of the claim limitations and Foxconn's device cannot literally infringe the asserted claims as a matter of law. As Berg has not asserted that Foxconn's device infringes under the doctrine of equivalents, we do not reach this issue.

A. "Substantially Unmagnetized"

The term "substantially unmagnetized" is contained in Claims 1 and 9 of the '028 patent, which are independent claims, and Claim 3 of the '028 patent, which is a dependent claim. Rotron contends that the term "substantially unmagnetized" need not be construed in a way that distinguishes the substantially unmagnetized sectors from the prior art, such as U.S. Patent No. 4,030,005 to Doemen ("Doemen '005"), because those sectors are inherently different than the change-over areas and pole gaps or clearances disclosed in the prior art. Accordingly, Rotron argues that the Court should adopt the following construction for this term: "The phrase 'substantially magnetized' includes sectors of field portions of the rotor magnets that have relatively weak magnetization relative to the adjacent magnetic poles of the permanently magnetized sectors. There is no numerical limitation on the amount of magnetization."

In contrast, Nidec argues the substantially unmagnetized sectors must be distinguished from the change-over areas disclosed in the prior art, particularly Doemen '005. It contends that the phrase should be construed as "a sector of a field portion of the rotor magnet wherein the magnetizable material has zero magnetization or as close to zero magnetization as possible in contrast to a 'change-over area' between the poles as disclosed in the prior art where the magnetization of one pole diminishes to zero and the magnetization of the next pole builds up to full strength." Nidec maintains that this construction is supported by the claims and the other portions of the specification, and argues that Rotron's proposed meaning would
improperly broaden its claims to cover the prior art.

Claims 1 and 9 do not define the term "substantially unmagnetized." However, Claim 1 provides some guidance, stating that the unmagnetized sectors of the field magnet portion are "substantially unmagnetized portions of the magnetic material." This language indicates that the patentee sought to distinguish "substantially unmagnetized" from simply "unmagnetized" sectors, and thus suggests that the substantially unmagnetized sectors need not have zero magnetization. Unfortunately, Claim 1 does not explain the extent to which the magnetization may vary from zero, and the ordinary meaning of the word "substantially"-"in a substantial manner" or "so as to be substantial"-also is practically useless as a guide for claim construction in this context. Thorn EMI North America Inc. v. Intel Corp., 936 F. Supp. 1186, 1199 (D. Del. 1996), aff'd, 157 F.3d 887 (Fed. Cir. 1998), cert. denied, 526 U.S. 1112, 119 S. Ct. 1756, 143 L. Ed. 2d 788 (1999). In other parts of the specification, however, including Claim 3 and the preferred embodiment, the patentee uses "unmagnetized" and "substantially magnetized" interchangeably, indicating that the terms may be defined similarly. See Amhil Enters. Ltd. v. Wawa, Inc., 81 F.3d 1554, 1559 (Fed. Cir. 1996) (noting that in a similar situation, "the entire specification . . . leaves its reader with the impression that 'substantially vertical' and 'vertical' mean essentially the same thing"). Similarly, the substantially unmagnetized sectors are also referred to as "null sectors." 028 pat. col. 6, ll. 63 & 68. This interpretation is further supported by the description of the method and apparatus for making the magnet contained in the preferred embodiment. Describing the features of the apparatus, the patentee states, "Relatively no magnetic field exists in the V-shaped cut-outs . . . and the corresponding sections of the ring . . . remain unmagnetized." 028 pat., col. 5, ll. 25-27.

The court next reviews the prosecution history to ascertain the meaning of the term "substantially unmagnetized," keeping in mind that the prosecution history should be used to understand the language used in the claims, but not to enlarge, diminish, or vary the limitations in the claims. See Markman I, 52 F.3d at 980. First, in explaining the difference in the creation of substantially unmagnetized sectors in the '028 patent and the prior art, the applicant referred to nulls as "the absence of magnetic fields." Defs.' Ex. 5, at 7.

Further, as stated above, Nidec contends that the prosecution history indicates that the nulls in the '028 patent must be distinguished from the prior art, particularly the pole clearances of Doemen '005. The prosecution history shows that the patent examiner twice rejected the patentee's claims as unpatentable, at least in part because the patentee's definitions of the unmagnetized portions of the field magnet did not sufficiently distinguish those structures from those contained in the prior art such as U.S. Patent No. 4,311,933 to Riggs ("Riggs '933"). As the examiner explained, "Magnetization between poles must always become zero at some point, because there can be no discontinuity in the magnetization vector." Defs.' Ex. 9, at 3-4; Ex. 10, at 2. His statement seemed to imply that prior art such as Riggs '933, which also claimed magnets with different poles, necessarily included areas of zero magnetization that could not be distinguished from the patentee's description of the null areas in the '028 patent. 1

--- Footnotes ---

1 The patent examiner indicated that it appeared obvious that the fabrication and assembly of Riggs '933 could have been used with the teachings of other patents, including Nakamura, Inariba, and U.S. Patent No. 3,299,355 to Wessels ("Wessels '355"), which all suggested unitary arrays of different magnetization systems.

--- End Footnotes ---

The patent applicant eventually amended his application to include new language in Claim 1, including the term "substantially unmagnetized," and new language in Claim 25 (which was eventually renumbered to become Claim 9) that used the phrase "substantially unmagnetized sectors of substantial angular length." In making this change, the applicant apparently attempted to distinguish these sectors from those claimed in other patents. He explained,

The unmagnetized sectors of substantial angular length differ, for example, from those locations where adjacent oppositely polarized field magnet sections convert from one polarization to another forming pole gaps or pole clearances as in the attached Muller patent No. 3,374,104 2 or Doemen Patent No. 4,030,005. There the field of one pole diminishes to the center of the gap where the field of the next pole begins to build up. There appears to be no unmagnetized area of any substantial extent, and even where Doemen extends this change-over area in the commutation section, it is for the purpose of gradually decreasing the field (to taper off the Hall generator response) and not to create a substantial effective angular null where there is insufficient magnetization to have an effect. It is believed that this is the kind of gradual change from one
polarity of magnetic field to another that the Examiner had in mind with respect to his last sentence on page 2 of the outstanding Official Action.

Defs.’ Ex. 6, at 12.

Footnotes

2 The applicant apparently intended to refer to U.S. Patent No. 4,099,104 to Muller (”Muller ’104”), which contains pole gaps.

Thus, the patent applicant explained that the nature of a pole gap or clearance and a null sector are two different things—the former is an area where "the field of one pole diminishes to the center of the gap where the field of the next pole begins to builds up," while the latter is an area that is unmagnetized. Therefore, Rotron's proposed meaning—that "substantially unmagnetized" should be construed as meaning relatively weak magnetization compared with the magnetized segments—appears not to sufficiently distinguish the prior art, and in particular, the pole clearances or extended change-over areas of Doemen '005. At the same time, the specification suggests that the term "substantially unmagnetized" should not be understood to be limited to areas with no magnetization at all. Accordingly, the Court finds that the specification and prosecution history supports a construction more similar to Nidec's proposed meaning, which allows for some variation from zero magnetization without improperly broadening the disputed term. The Court thus adopts the following construction of "substantially unmagnetized": "having zero magnetization or as close to zero magnetization as possible."
would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. To modify Zabner et al by providing portion 44 as discontinuous portions with a substantially vertical face, side edges and side walls would be obvious in view of Davis.

Defendant's Exhibit 8, p. 33. Claim 1 of the Zabner patent discloses a downwardly extending peripheral skirt containing "a plurality of peripherally spaced inwardly directed generally U-shaped detents . . ." Defendant's Exhibit 9, col. 4, lines 12-17. In challenging the rejection, the patentee argued that the "substantially vertical" outer faces and side edges of the projections distinguish his invention from the Zabner lid by allowing his lid to be easily stripped from the mold "while still providing the much deeper undercut that gives the lid of the present invention a much greater advantage over the Zabner lid." Exhibit 8, p. 41. By emphasizing this distinction between and advantage of his lid over the prior art, the patentee established that the "substantially vertical" faces, side walls and side edges of the projections on his invention excluded ones "inwardly directed," or sloped, such as those referenced in the Zabner patent. Amhil may not now attempt to recapture that element which it specifically and intentionally excluded in order to obtain its patent. Patent claims must be construed the same way for both patentability and infringement. See Smithkline Diagnostics, Inc. v. Helena Laboratories Corp., 859 F.2d 878, 882 (Fed. Cir. 1988); W.L. Gore & Associates, Inc. v. Garlock Inc., 842 F.2d 1275, 1279 (Fed. Cir. 1988).

Applying the claim language to the accused lid reveals that literal infringement has not occurred. Each projection on the M & N lid contains a face that slopes upwardly and inwardly towards the peripheral cavity. The edges and side walls of the projections extend downwardly and laterally outwardly to form a sloped facade with a trapezoidal appearance, thereby distinguishing the projections from those described in the patent-in-suit.

The accused lid does not infringe on Amhil's patent under the doctrine of equivalents either. As discussed above, the doctrine of file wrapper estoppel precludes Amhil from expanding the claims in its patent to include any projections which lack "substantially vertical" faces, side walls, and side edges. The sloped segments of the projections on M & N's lid place it outside the reach of the patent-in-suit, requiring a conclusion of non-infringement as a matter of law.

C. Claim Construction

"Because claim construction is a matter of law, the construction given the claims is reviewed de novo on appeal." Markman, 52 F.3d at 979, 34 U.S.P.Q.2D (BNA) at 1329. Claim 1, the only independent claim in the '244 patent and the only claim at issue here, Amhil II, 34 U.S.P.Q.2D (BNA) at 1647, reads as follows (material in parentheses and brackets added) (emphasis added to contested language):

1. A lid (10) for containers (12), made of thin, flexible plastic, for mounting on and receiving the bead (14) of a container (12), comprising:

   a central panel (16);

   a cavity (20) extending around the periphery of the lid (10) and opening downwardly and inwardly to receive the bead (14) of a container (12) to which said lid (10) is fitted;

   means (22,24) connecting said cavity (20) to said central panel (16);

   a skirt portion (26) extending downwardly from said cavity (20);

   said skirt portion (26) having a plurality of outwardly extending projections (28), each having a substantially vertical face (100) with substantially vertical side edges (102), and substantially vertical side walls (30) extending inwardly from said face (100);

   the portions (32) of said skirt (26) that are between said outwardly extending projections (28) extending inwardly to a waist portion (34) having [sic, having] a plurality of interruptions (104), one at each projection (28), and forming an undercut defining said cavity (20) in said waist portion (34) [sic, said lid (10)].
said outwardly extending projections (28) and said waist portion (34) [sic, said portions (32)--see col. 4, ll. 33-36 and figures 1-3 above] all terminating in their lower extremities at a downwardly and outwardly sloped lower band portion (36);

and said outwardly extending projections (28) terminating in their upper extremities at a respective upper, band portion (42) extending inwardly and upwardly from the upper edge [edge between each portion (42) and projection (28)] of each said respective vertical face (100) and terminating at said cavity (20) in an upper undercut (44) which is higher and less inwardly extending than the undercut of said waist portion (34), and which defines the peripheral cavity [part of entire cavity (20)] over said outwardly extending projections (28).

M&N and Amhil focus their claim construction arguments on two primary issues:

(1) whether the "cavity" (compare element 20 in figures 2 and 3 above, which are figures from the '244 patent, with element 20 in figure 4 above, which depicts the accused M&N lid) of the accused lids opens "downwardly and inwardly" as required by the third paragraph of claim 1, and

(2) whether the "outwardly extending projections" of the accused lids have "substantially vertical" faces (compare element 100 in figures 1-3 above, which are figures from the '244 patent, with element 100 in figure 4 and the portion labeled "Face" in figure 8 below, which depict the accused M&N lid), side edges, and side walls as required by the sixth paragraph of claim 1.

--- Footnotes ---

1 The '244 patent does not contain reference numbers for the faces, the side edges, or the interruptions. We have added reference numbers 100, 102, and 104 to figures 1-3 above to refer to the faces, the side edges, and the interruptions, respectively.

--- End Footnotes ---

Looking at issue (2), we note that the sixth paragraph of claim 1 requires the skirt portion to comprise a plurality of "outwardly extending projections," each having a "substantially vertical face" with "substantially vertical side edges," and "substantially vertical side walls." It is clear from the specification that the adverb "outwardly" means in a direction from inside the container to outside the container and perpendicular to the container's longitudinal axis. The parties hotly contest how to define the effect of the "substantially vertical" limitation as it relates to the faces, side edges, and side walls on the outwardly extending projections.

It is apparent that the faces 100 of the outwardly extending projections 28 in the preferred embodiment of the '244 patent are vertical. This may be seen, for example, in figures 2 and 3 above and is also evident from the description of the side edges 102 in the preferred embodiment as being vertical. A preferred embodiment, however, is just that, and the scope of a patentee's claims is not necessarily or automatically limited to the preferred embodiment. The entire specification, including all of the claims, the prosecution history, and the prior art may all affect the interpretation ultimately placed on claim language.

We first review the entire specification, including all of the claims. In the specification, the patentee used "substantially vertical" and "vertical" interchangeably when describing the faces of the projections. Even within claim 1, the patentee used "substantially vertical face" interchangeably with "vertical face." Compare P 6 ("substantially vertical face") with P 9 ("vertical face"). The entire specification thus leaves its reader with the impression that "substantially vertical" and "vertical" mean essentially the same thing in the '244 patent, at least as to the faces.

We next review the prosecution history of the '244 patent to ascertain the true meaning or effect in the claims of the adverb "substantially" in the claim limitation "substantially vertical faces." The prosecution history, in addition to being used while considering the factual issue of infringement and whether prosecution history estoppel places any limitations on what infringes a claim, should also be used when considering the legal issue of proper claim construction. SSIH Equip. S.A. v. United States Int'l Trade Comm'n, 718 F.2d 365, 376, 218 U.S.P.Q. (BNA) 678, 688, 1 Fed. Cir. (T) 90, 102 (1983) (prosecution history "is always relevant to a proper interpretation of a claim") (citing Astra-Sjuco A.B. v. United States Int'l
Trade Comm'n, 67 C.C.P.A. 128, 629 F.2d 682, 686, 207 U.S.P.Q. (BNA) 1, 5 (CCPA 1980); Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 395-99, 155 U.S.P.Q. (BNA) 697, 701-04 (Ct. Cl. 1967)). An examination of the prosecution history is particularly important where, as in the instant case, the claimed invention is in a crowded art.

During prosecution of the application for the '244 patent ('244 application), the examiner, inter alia, rejected the claims under 35 U.S.C. § 103 as unpatentable over U.S. Patent No. 4,194,645 (Zabner '645) in view of U.S. Patent No. 3,353,708 (Davis '708). Fig. 3 of Zabner '645 is reproduced below as figure 5. Figs. 1 and 4 of Davis '708 are reproduced below as figure 6. According to the examiner, "to modify [Zabner '645] by providing portion 44 as discontinuous portions with a substantially vertical face, side edges and side walls would be obvious in view of [Davis '708]." Portion 44 of Zabner '645 corresponds to face 100 in the '244 patent. The examiner thus opined that the lid described in Zabner '645 closely approximated the lid claimed in the '244 application, the main difference between the two being the claimed substantially vertical faces, side edges, and side walls.

[SEE ILLUSTRATIONS IN ORIGINAL].

In response to the § 103 rejection, the patentee asserted that, unlike Zabner '645, the lid claimed in the '244 application had projections with substantially vertical faces and side edges, making the '244 lid easy to strip from the mold, while providing a much deeper undercut. Since the patentee distinguished Zabner '645 based in part on the slope of the projection faces, "substantially vertical" may be properly interpreted as not including lids with sloping faces like those of Zabner '645. In this regard, one should also note the sloped faces of the Mahaffy '036 lid depicted in figure 7 below.

[SEE ILLUSTRATION IN ORIGINAL].

We also note that, during prosecution of the '244 application, the patentee again used "substantially vertical" and "vertical" interchangeably when describing the faces of the projections. For example, in his response to the first office action, the patentee alternated, first referring to the faces as "substantially vertical" then "vertical" then "substantially vertical" then "vertical" then "substantially vertical." This provides a further indication that the patentee thought of his substantially vertical faces as essentially vertical.

Finally, it is apparent from our review of the prior art of record that lids of the general construction claimed in the '244 patent were common in the industry. Several prior art lids depict outwardly extending projections with variously sloped outward faces as may be seen in the figures from some prior art lid patents reproduced in the attached appendix. In order for claim 1 of the '244 patent to "avoid" these prior art lids, "substantially vertical face" must be construed as the same as or very close to "vertical face." See ACS Hosp. Sys., Inc. v. Montefiore Hosp., 732 F.2d 1572, 1577, 221 U.S.P.Q. (BNA) 929, 932 (Fed. Cir. 1984) ("claims should be so construed, if possible, as to sustain their validity").

We conclude from our review of the district court's opinion and from our de novo review of the entire specification, the prosecution history, and the prior art that claim 1 does not permit Amhil to exclude from the marketplace lids having protrusions with sloping faces like the faces shown, for example, in Zabner '645 and Mahaffy '036. In particular, we interpret claim 1 to include only lids wherein the outwardly extending projections have well-defined faces that deviate only slightly, if at all, from the vertical. Any other construction of claim 1 would render it invalid.

3982

C. "substantially vertically"

The court finds that the term "substantially vertically" means "substantially perpendicular to the horizon."

Claim 1 provides that "said accessory clamp can be pivoted about said mounting shaft between a first, inactive position adjacent the firearm and a second, active position protruding substantially vertically from said firearm." Defendant would have the court construe the term "substantially vertically" to mean "being or situated at right angles to the horizon; upright." As a definition of "vertical," the proposal is unproblematic. However, it fails to reflect the effect of the adverb "substantially," which renders the requirement of verticality somewhat less stringent.

- 4649 -
Plaintiff argues that neither the term "substantial" nor the term "vertical" requires construction, and the court therefore adopts its own construction, as set forth above.

B. "Disposed Substantially Vertically in Said Grooves"

The parties also dispute what the word "vertically" means in the context of this claim language. Paradigm contends that "vertically" is an absolute term that means that the diodes are vertical in relation to the horizon, i.e. that they are perpendicular to the horizon when the array is lying on a flat surface. In Paradigm's view, anything that is "vertical" runs along an imaginary axis running through the center of the earth.

LDAI, on the other hand, takes the position that "vertically," as used in the '951 patent, is a relative term that refers to the position of the diodes with respect to the grooves themselves. In other words, "disposed substantially vertically in said grooves" means that the bars do not "tilt" very much within the grooves. LDAI also contends that the diodes in Paradigm's arrays are "vertical" with respect to the point at which they meet the surface of the conductive layer, since they are directed toward the center of the cylinder.

With respect to this language, I find Paradigm's interpretation more persuasive. For one thing, I believe that the common-sense understanding of "vertical" or "vertically" is that those words convey a sense of perpendicularity with respect to the surface of the earth. Those words are commonly understood to refer to an object's orientation with respect to the earth itself, not to individual objects on the earth. Thus, if a person, standing erect, were to aim a laser beam directly away from himself, i.e. at a right angle to his body, one would not describe the beam as traveling vertically, but horizontally. If one wanted to describe the path of the beam relative to the person aiming it, one would describe it as traveling perpendicularly to that person.

In essence, then, LDAI's interpretation of this language seeks to equate verticality with perpendicularity. Under the terms of the '951 patent, however, the grooves themselves are vertical, i.e. perpendicular to the horizon, when the array is at rest on a flat surface, and the clear implication of "disposed substantially vertically" is that the bars are likewise vertical; in other words, the bars are not placed in the grooves crosswise or horizontally, but vertically, like the grooves themselves. In a device like Paradigm's, LDAI's interpretation would mean that the bars are all vertical at once, even though none of them is parallel to the bars adjacent to it. That simply makes no sense. Even assuming that an object can have its own verticality independent of reference to the earth's horizon (e.g. a piece of graph paper may have a "vertical" y axis drawn on it even though that paper is lying flat on a table, so that they axis is actually horizontal with respect to the earth), it is difficult to see how it can have multiple verticalities, which is essentially what LDAI contends.

In short, LDAI's interpretation is not supported by the claim language, and nowhere do the specifications suggest that the word "vertically" is being used in a manner inconsistent with its ordinary meaning. See Vitronics, 90 F.3d at 1582; cf. Fireplace Mfrs. v. Hearth Techs., 1997 U.S. Dist. LEXIS 21966, *24, No. 4-96-1080 (D.Minn. Dec. 10, 1997) ("The phrase 'horizontal exhaust pipe' must be given its ordinary meaning. Nothing in the claims, specification, or prosecution history suggests otherwise. In short, 'horizontal' means 'horizontal'; it does not mean 'horizontal and vertical,' 'angled,' or even 'substantially horizontal.'"). I conclude that as used in the '951 patent, "vertically" means that the bars are disposed substantially in a vertical direction, i.e., a direction that is perpendicular to the plane of the horizon, or parallel to a plumb line through the center of the earth, when the array is resting on a flat, horizontal surface.

a. "substantially within a shirt pocket"

The plain and ordinary meaning of the "substantially within a shirt pocket" limitation is that the device claimed in the '496 Patent must fit in the pocket found on the chest of an average size man's dress shirt. That is evident from the plain meaning of the non-technical words of the limitation. The small size requirement of the claimed device is confirmed at other points in
Claim One. The claim states that the handheld unit is "dimensioned for handheld grasping," and it states that all of the device's components must fit in "a handheld housing." '496 Patent, 8:63, 9:10. The specification further supports this construction, stating that the preferred embodiment of the housing "should be about what may be comfortably grasped in a human operator's hand and fit within a conventional shirt pocket for ease of use carrying, e.g. about 1.8 inches (4.6 cm) wide, 6.25 inches (15.9 cm) long and 0.8 inches (2.0 cm) thick with rounded edges." Id., 4:1-5. See also id., 8:44-45 (stating that the device's housing "is portable, handheld and adapted for convenient carry in a shirt-pocket"). The specific dimensions mentioned in the specification are not part of the limitation, but they confirm the plain meaning of the language.

Casio argues that "shirt pocket" should be construed to include all possible shirt pocket sizes, including pockets that are much larger than those of a standard dress shirt. However, to determine the meaning of a term, it is not appropriate to rely on rare or unusual uses of that term, since such versions cannot be described as embodying the term's "ordinary meaning." See Nat'l Recovery Techs., Inc. v. Magnetic Separation Sys., Inc., 166 F.3d 1190, 1195 (Fed. Cir. 1999) (patent term given its "plain and ordinary meaning" unless something in the patent or prosecution history compels otherwise). Since the claims themselves and the specification all indicate that the phrase "fits substantially within a shirt pocket" refers to a small device which can be grasped in one hand, Casio's argument that "shirt pocket" should be construed to include the pockets of unusually large shirts is not persuasive.

The above construction of the term "stowed" also recommends a similar construction of the terms "substantially within it" used in the claim language in referring to the positioning of the anchor member when the anchor member is in its retracted position. The prosecution history of the patent similarly dictates that the anchor member be, in all material parts, within the bulkhead housing to prevent tripping. This reading is also confirmed by the specification language which refers to this element of the claim by referencing drawings showing that the anchor member is entirely enclosed in the housing and shut within a door so that no material portion of the anchor member and belt assemblies are seen by passengers. ('325 patent at col. 5, lines 10-15, figures 2 and 7.) The function of the door makes it physically impossible for material parts of the anchor member to extend from the housing when in the retracted position. Finally, the descriptions of the allegedly infringing A.R.M. products in drawings and in the Adelsperger Declarations make clear that the products do not function as described in this claim language since a significant portion of the anchoring device is not retracted in both models of the A.R.M. product.

3. What is the meaning of the phrases "substantially zero overlap" and "substantially aligned"?

Throughout this litigation, Intel has asserted that "substantially zero overlap" and "substantially aligned" mean that the edges of the source/drain regions cannot overlap the edges of the gate electrode to any degree. By contrast, TENA has contended that "substantially zero overlap" and "substantially aligned" do not require perfect alignment. Rather, TENA asserts that these phrases allows for a tolerance of +/-10% of the gate electrode length. Neither argument has much credibility.

a. Does the patent require zero overlap and perfect alignment?

Intel essentially wants the court to read the word "substantially" out of the claims. Intel argues that the claims, the specification, and the prosecution history use the phrases "zero overlap/perfect alignment" and "substantially zero overlap/substantial alignment" interchangeably. For example, the title of the patent, the abstract, the summary of the invention, and the preambles of claims 1, 10, and 15 recite "zero overlap," "perfect alignment," and "non-overlapping," whereas the preferred embodiment and step (e) of each claim recite phrases such as "closely aligned," "substantially aligned," "without substantial overlap," and "substantially zero overlap." Moreover, in Amendment B and the First Proposed Amendment, Manzo refers to "zero drain overlap devices" and "perfect alignment" in describing the inventions of the '943 patent.
Intel relies heavily on Amhil Enterprises Ltd. v. Wawa, Inc., 81 F.3d 1554 (Fed. Cir. 1996). In Amhil, the Court of Appeals for the Federal Circuit construed the phrases "substantially vertical sides," "substantially vertical side edges," and "substantially vertical side walls." The court observed that the preferred embodiment was completely vertical but stated that this was not determinative. Id. at 1559. Examining the entire specification, the court stated that the patentee used "substantially vertical" and "vertical" interchangeably, even within the claims themselves. Id. Examining the prosecution history, the court stated that the patentee narrowed "substantially" to overcome similar prior art and again used "substantially vertical" and "vertical" interchangeably. Id. at 1559-62. Finally, the court stated that to avoid prior art in a crowded field, "substantially vertical face" had to be construed "as the same as or very close to 'vertical face.'" Id. at 1562.

Although Amhil is certainly helpful in construing the claims, it is not precisely on point. The invention in Amhil, which is related to plastic coffee mug lids, involves a large physical structure whose dimensions are relatively easy to control and measure. By contrast, the invention of claim 1 of the '943 patent is submicroscopic and has dimensions that are difficult to control and measure. In addition, the '943 patent does not use the terms "substantially aligned" and "aligned" or "substantially vertical" and "vertical" interchangeably within the claims themselves. Furthermore, the Federal Circuit seemed to rely primarily on the fact that the invention in Amhil was in a crowded art that compelled a narrow construction. Finally, the court still found that "substantially" had some meaning in the claim, albeit a very narrow meaning. Therefore, Amhil does not support Intel's effort to deprive "substantially" of any meaning whatsoever.

b. Does the patent allow for a tolerance of +/- 10%?

TENA wants to give the word "substantially" a broad, specific numerical reading. TENA points to the declaration and testimony of Dr. Fair, who defines "substantially zero overlap" and "substantially aligned" as allowing a tolerance as +/-10% of the drawn gate length based on his "knowledge of MOS transistors." TENA also points to the specification, at column 1, lines 21-23, which uses the phrase "substantially aligned" in discussing the prior art: "Conventional fabrication techniques usually cause the edges of the source/drain regions to be initially substantially vertically aligned with the edges of their gate." Dr. Fair asserts that the alignment of these conventional fabrication techniques was within +/-10% of the gate electrode length. Finally, TENA observes that one of Intel's experts, Dr. Frey, testified in a previous litigation that the term "substantially aligned" allowed for tolerances of +/-10% of the gate electrode length.

TENA's evidence is less than convincing. It appears from Dr. Frey's previous testimony that he identified a range of +/-5% on either side of the edge of the gate electrode, making a total range of 10% instead of +/-10% for a total range of 20%. In addition, Dr. Chung testified, and Dr. Fair appeared to confirm, that an underlap of -10% would drastically reduce the performance of an MOS transistor, particularly with respect to the problem of Miller capacitance that the '943 patent seeks to avoid. Finally, Dr. Fair has not cited to anything in the claims or prosecution history in support of his opinion that the +/-10% range is appropriate. His attempt to bootstrap his definition of "substantially" in the claims by defining the word "substantially" in the specification to mean the same thing is questionable without some objective basis.

c. What does "substantially" mean?

The word "substantially" tends to become somewhat of a chameleon when it appears in patent claims. It sneaks in during the prosecution of a patent application without having much substance or importance. The applicant rarely imposes strict mathematical requirements or guidelines for the word unless forced to do so by the examiner or by the prior art. After the issuance of the patent, however, the word swells up to envelop potentially infringing products or processes. The plaintiff's expert opines that a specific percentage range exists and, coincidentally, that the range encompasses the defendant's accused products or processes. Likewise, the defendant's expert opines that a smaller range exists that, coincidentally, does not encompass the defendant's accused products or processes.

Courts are in a bind when it comes to construing the word "substantially." On the one hand, the court has a duty according to Markman to construe the word to provide guidance to the jury as to the proper scope of the claim for determining infringement. This duty is particularly important when the parties' experts have testified to conflicting mathematical ranges required by the claim. Moreover, the ordinary meaning of the word "substantially" -- "in a substantial manner" or "so as to be substantial" -- is practically useless as a guide to understanding or decision. On the other hand, a court should not impose mathematical certainty on a word when none exists. Often the claims, the specification, the prosecution history, and even all the extrinsic evidence will fail to provide any reasonable basis for selecting a mathematical range.
In the present case, the specification and the prosecution history present only theoretical limits to the percentage range allowed by the word "substantially." The specification states that the amount of overlap and alignment must be sufficient to prevent the occurrence of Miller capacitances in order to increase the speed of the transistor, but it does not provide a mathematical reference. During the prosecution, Manzo specifically defined "substantially zero overlap" and "zero drain overlap" over the results achieved by Figure 10 of U.S. Patent No. 4,356,623 issued to Hunter, Figure 4D of EPO publication 24 125, and the Steinmaier patent, but he never provided a mathematical explanation of the prior art process. Furthermore, the parties have never offered extrinsic evidence to suggest mathematical ranges based on these theoretical limits, and the court lacks sufficient understanding or skill to ascertain such ranges itself.

The parties instead have offered what appear to be litigation-driven constructions of the term "substantially" that have little support in the claim language, the specification, the prosecution history, or the extrinsic evidence. Intel's construction seeks to write the word out of the patent and to impose a level a mathematical certainty that does not appear physically possible. By contrast, TENA's construction ignores a specific goal sought by the inventions of the '943 patent and argued by Manzo extensively during the prosecution history: manufacturing an MOS transistor with as little overlap as possible to improve operating speed and reduce Miller capacitances. Thus, at the end of the claim construction hearing, the court was compelled to reject both parties' constructions in favor of its own.

The court adopted the following construction of the word "substantially" -- "the same as or very close to." In other words, "substantially zero overlap" means "the same as or very close to zero overlap" and "substantially aligned" means "the same as or very close to perfect alignment." The court bases this construction on the many references to zero overlap and perfect alignment in the patent and the prosecution history and the stated importance in the specification of near-perfect alignment for the speed and efficiency of the inventions of the '943 patent. No further guidance is possible, however, because nearly every attempt to restate the word "substantially" adds little to its inherent meaning.

---

The parties essentially agree that a substrate is a material suitable for receiving a thermal transfer laminate. Avery's proposed definition states: "A material suitable for receiving a thermal transfer laminate such as a seatbelt or automotive visor." Whitlam's definition states: "a layer of base material suitable for receiving a thermal transfer laminate that may be made of: metal, plastic, leather, paper, or the like; a woven or non-woven fabric made of natural or synthetic materials. A substrate may comprise an automotive interior surface such as the surface of a seatbelt, visor, dashboard, headrest, seat-back, door panel, etc." Both of theses definitions convey the same message, but Whitlam's is excessively verbose. Given the Court's charge to construe claim terms according to their ordinary meanings, See Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1369 (Fed. Cir. 2003), this court finds that an exhaustive list of the types of substrates used is not necessary to convey the ordinary meaning of the term substrate. Therefore, this Court adopts the following definition of substrate: "A material suitable for receiving a thermal transfer laminate, such as a seatbelt or automotive visor."

---

The court concedes the term "substrate" to mean "a flat, thin disk-shaped sheet of hardened transparent material." The court does not read the term "substrate" as used in the claim language to require a specific thickness, despite MEI's position that the term "substrate" is limited to a thickness of approximately 0.6 mm. The specification provides for a thin substrate. (See '634 patent, col. 8, ll. 53-61; col. 21, ll. 24-29) However, the specification does not define a "substrate" as having a thickness of approximately 0.6 mm. Example 1 and Figure 3 of the specification merely relate to one
embodiment of the claimed invention where the thickness of the substrate happens to be 0.6 mm. (See '634 patent, col. 10, ll. 60-63; fig. 3) The specification describes eight other examples where the thickness of the substrate is not restricted to approximately 0.6 mm.

B. Second Substrate

Plaintiff's Proposed Construction: a support

Defendant's Proposed Construction: a material that is modified to contain discrete individual sites appropriate for the attachment or association of beads (small discrete particles) and is amenable to at least one detection method.

With respect to each of the terms in dispute, the parties said little in their briefs or at the claim construction hearing about plaintiff's proposed constructions; instead, they focused almost exclusively on whether defendant's proposed constructions are correct. The issue in dispute for the term "second substrate" is whether the definition includes a requirement that the substrate's surface allows "for the attachment or association of beads." Beads are "small discrete particles" that represent one way to detect the "target analyte." The patents use the words "bead" and "microsphere" interchangeably. '841 patent, col. 8, ln. 36.

Defendant relies primarily on one passage from the specification, which it says represents a definition of the word "substrate" in the context of the patent:

'841 pat., col. 7, lns. 32-36. Defendant cites case law in which the Court of Appeals for the Federal Circuit has held that "a definition set forth in the specification governs the meaning of the claims." Sinorgchem Co., Shandong v. International Trade Commission, 511 F.3d 1132, 1136 (Fed. Cir. 2007). See also Martek Biosciences Corp. v. Nutrinova, Inc., 579 F.3d 1363, 1380 (Fed. Cir. 2009) ("When a patentee explicitly defines a claim term in the patent specification, the patentee's definition controls."); Phillips v. AWH Corp., 415 F.3d 1303, 1321 (Fed. Cir. 2005) (en banc) ("[T]he specification 'acts as a dictionary when it expressly defines terms used in the claims.") (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)).

To support its view, plaintiff cites a passage from the specification stating that "[i]t should be noted that while the disclosure herein emphasizes the use of beads, beads need not be used in any of the embodiments of the invention; the bioactive agents can be directly coupled to the array locations." '841 patent, col. 5, lns. 3-4. In addition, plaintiff cites other passages discussing "non-bead" embodiments. E.g., id. at col. 8, lns. 25-29 ("In these embodiments, at least one surface of the substrate is modified to contain discrete, individual sites for later association of microspheres (or, when microspheres are not used, for the attachment of the bioactive agents"). Figure 1B represents one such embodiment:

[SEEF FIG. 1B IN ORIGINAL]

In this figure, "beads are not used; rather, array locations 20 have discrete sites 21, 22, 23, etc. that may be formed using spotting, printing, photolithographic techniques, etc." '841 pat., col. 3, lns. 33-36.

How can these different passages be reconciled? Plaintiff's answer is to characterize defendant's cited passage as the description of an embodiment rather than of the invention as a whole. Defendant's answer is to disregard all references to non-bead embodiments on the ground that the claims do not cover them. However, neither party cites anything in the patent to support its view of the limited scope of the other side's cited passages. Plaintiff cites no authority for the view that a court may disregard a passage in the specification that puts a term in quotation marks and states unequivocally what "is meant" when that term is used "herein." Sinorgchem, 511 F.3d at 1136 (quoting Abbott Labs. v. Andrx Pharms., Inc., 473 F.3d 1196, 1210 (Fed. Cir. 2007)) ("[W]hen a term is set off by quotation marks" and is followed immediately by the word "is," these
Defendant objected on the ground that adopting the definition as is "would allow [plaintiff] to game the system" by an argument for rejecting the definition. "Beads are not required in Substrate 1." Trans., dkt. # 34, at 35. However, that is simply a restatement of plaintiff's legal position rather than construction, counsel's only concern was that the construction should be clear that "the second substrate in the claims and that 'second substrate' do not have different meanings. 3M Innovative Properties Co. v. Avery Dennison Corp., 350 F.3d 1365, 1371 (Fed. Cir. 2003) ("The use of the terms 'first' and 'second' is a common patent-law convention to distinguish between repeated instances of an element or limitation."). Further, if, as defendant concedes, the proper construction for one of the substrates is that it "can be" modified to allow the attachment of beads, this is more support for the view that both substrates should be defined this way. Defendant's only argument to the contrary in its briefs is a sentence in a footnote that the definition should be changed from "can be" to "is" in the context of the "second substrate" because "every . . . claim [disclosing a 'second substrate'] expressly states that the second substrate has discrete sites." Dft's. Br., dkt. # 31, at 6. The argument becomes even more convoluted when defendant says that its proposed construction should apply to the term "substrate," standing alone," but only in one instance in the context of claim 20 of the '020 patent. Dft's. Br., dkt. # 25, at 7 n.7.

These arguments hurt defendant's position more than they help. The patent's treatment of the adjectives "first" and "second" as interchangeable when they are used to modify "substrate" supports a reading that the terms "first substrate" and "second substrate" do not have different meanings. 3M Innovative Properties Co. v. Avery Dennison Corp., 350 F.3d 1365, 1371 (Fed. Cir. 2003) ("The use of the terms 'first' and 'second' is a common patent-law convention to distinguish between repeated instances of an element or limitation."). Further, if, as defendant concedes, the proper construction for one of the substrates is that it "can be" modified to allow the attachment of beads, this is more support for the view that both substrates should be defined this way. Defendant's only argument to the contrary in its briefs is a sentence in a footnote that the definition should be changed from "can be" to "is" in the context of the "second substrate" because "every . . . claim [disclosing a 'second substrate'] expressly states that the second substrate has discrete sites." Dft's. Br., dkt. # 31, at 6. The argument becomes even more convoluted when defendant says that its proposed construction should apply to the term "substrate," standing alone," but only in one instance in the context of claim 20 of the '020 patent. Dft's. Br., dkt. # 25, at 7 n.7.

Finally, even if defendant had a plausible basis for distinguishing the "first substrate" from the "second substrate," defendant's view would still require adopting inconsistent meanings for "substrate." In particular, defendant argues that the term "substrate" in claim 20 of the '020 includes the same bead limitation as the term "second substrate," even though defendant asserts that "substrate" and "second substrate" have different meanings elsewhere. Defendant does not explain or justify that inconsistency. Fin Control System Pty., Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001) (courts apply "presumption that the same terms appearing in different portions of the claims should be given the same meaning unless it is clear from the specification and prosecution history that the terms have different meanings at different portions of the claims").

At the claim construction hearing, when I suggested adopting a construction of "second substrate" that was identical to the definition in the specification, neither party raised a persuasive objection. Although plaintiff did not embrace that construction, counsel's only concern was that the construction should be clear that "that the second substrate in the claims does not require beads." Trans., dkt. # 34, at 35. However, that is simply a restatement of plaintiff's legal position rather than an argument for rejecting the definition.

Defendant objected on the ground that adopting the definition as is "would allow [plaintiff] to game the system" by
"get[ting] everything in the expressed definition," but then "us[ing] the word[s] 'can be' . . . as an escape hatch." Id. at 110. However, it is difficult to see the logic in an argument that it allows plaintiff to "game the system" by adopting a construction that incorporates language used in the patent; plaintiff does not "get away with" anything if it is held to the words it chose. If a reader interpreted "can be" to mean "is," that is not plaintiff's fault, particularly because there are other passages in the specification rejecting the view that beads are always required.

Defendant points to two other passages to show that a bead limitation should be included:

The present invention is generally based on previous work comprising a bead-based analytic chemistry system in which beads, also termed microspheres, carrying different chemical functionalities are distributed on a substrate comprising a patterned surface of discrete sites that can bind the individual microspheres.

* * *

It should be noted that a key component of the invention is the use of a substrate/bead pairing that allows the association or attachment of the beads at discrete sites on the surface of the substrate, such that the beads do not move during the course of the assay.

'841 pat. col.5, lns. 34-39; id. at col. 17, lns. 50-54.

Neither of these passages shows persuasively that the invention generally or substrates specifically include a bead limitation. The first passage is a description of the prior art. Even if the invention is "generally based on" prior art that uses beads, that does not mean that the invention is limited to embodiments that use beads.

The second passage is included in a larger discussion of preferred embodiments that use beads. '841 pat., col. 17, lns. 20-21 ("In a preferred embodiment, the compositions of the invention further comprise a population of microspheres."). Thus, in context, the passage cited by defendant is best read as a description of a preferred embodiment. That is, when beads are used, it is important that they "do not move during the course of the assay." Although the passage uses the word "invention," that "does not 'automatically' limit the meaning of claim terms in all circumstances . . . [S]uch language must be read in the context of the entire specification and prosecution history." Netcraft Corp. v. eBay, Inc., 549 F.3d 1394, 1398 (Fed. Cir. 2008). In light of the other passages stating clearly that the invention does not include a bead limitation, I decline to read this passage as suggesting a contrary view.

Finally, defendant has not pointed to anything in the prosecution history that would require this court to adopt a bead limitation. Defendant did not discuss the prosecution history in its briefs, but at the claim construction hearing, it cited one page in which the patent examiner considered three dependent claims that would later become claims 7, 8 and 9 in the '841 patent. These claims disclose different densities of "bioactive agents per square centimeter." Defendant says that the examiner must have believed that beads were required by the invention because the examiner used the phrase "claimed microspheres" in rejecting the claims as obvious under Burbann, who had "describe[d] the use of beads" at particular densities. Chin Decl., dkt. # 26, exh. O, at 14.

This reference is far too ambiguous to require adopting defendant's proposed construction. If the examiner believed that the invention included a bead limitation, it is odd that the only context in which the examiner would make this observation is in one phrase when rejecting dependent claims. Both Burbann and claims 7, 8 and 9 address density, so that is most likely the only issue the examiner was considering in rejecting those three claims.

Court's construction: "a material that can be modified to contain discrete individual sites appropriate for the attachment or association of beads and is amenable to at least one detection method"
construction because its plain meaning is understood by one of ordinary skill in the art.

Vistakon argues that although the plain language of this phrase does not indicate that the first correction value and that the second correction value must each be the same in each zone, the examiner allowed this claim "with the understanding that the first correction values should be the same and the second correction values should be the same." Vistakon contends that the examiner rejected a claim that included the language: "all of said regions of high optical powers not necessarily having a uniform width or a uniform high optical power, and all of said regions of low optical powers not necessarily having a uniform width or a uniform low optical power," as "new matter" because "nowhere is it disclosed that these high and low powers can be anything different" and only issued the amended claim as Claim 17 in the '461 Patent after Portney amended it to remove the objectionable language. According to Vistakon, the Examiner issued claim 17 of the '461 patent only after the objectionable language was removed and with the understanding that the "high" and "low" optical powers in the different regions of the Portney lens were the same.

The Court disagrees with Vistakon's reliance on the prosecution history. As an initial matter, the Court declines to speculate on the Examiner's "understanding" beyond what is stated in the record. Vistakon's argument relies on the meaning of the statement that "[n]owhere is it disclosed that these high and low powers can be anything different." Does that mean, as Vistakon urges, that the powers must be the same in each zone? The Court finds that the Examiner's comments are unclear as to what "anything different" refers. The preceding sentencing in the prosecution history refers to various features related to the high and low powers in each zone, e.g., a transition from high to low and the "high and low powers [are] defined as those powers to correct for near vision and distant vision." "Anything different" might refer to the relationship of the powers, just as described, rather than the powers being the same. Additionally, the argument raised by Vistakon relates to claim 17, not claim 1 where the language at issue appears. Therefore, this does not amount to an express or unequivocal disclaimer as Vistakon suggests. Middleton, Inc. v. Minn. Mining & Mfg. Co., 311 F.3d 1384, 1388 (Fed. Cir. 2002).

Vistakon acknowledges that the plain language of this phrase does not indicate that the correction values must be the same in each zone. Because the Court concludes that the prosecution history does not change the plain meaning of that phrase, the Court finds that no construction is necessary.

3991
11. "Folding . . . Such That"

The term "folding . . . such that" is found only in the method claims of the patents-in-suit. For example, in Claim 1 of the 779 Patent, a method claim, step (d) of the seam manufacturing process requires "folding the first garment component over the bonding element such that the upper surface of the first garment component is folded over and abuts an upper surface of the bonding element." 779 Patent at 6:40-43 (emphasis added). Also in Claim 1 of the 779 Patent, step (e) of the seam manufacturing process requires "folding a portion of the second garment component such that a lower surface of the second garment component abuts the lower surface of the bonding element." 779 Patent at 6:44-46 (emphasis added). In Claim 1 of the 615 Patent, step (e) requires "folding the first garment component over the bonding element such that the upper surface of the first garment component is folded over and abuts an upper surface of the bonding element along the seam. . . ." 615 Patent at 6:48-51 (emphasis added).

Taltech asks the Court to construe "folding . . . such that" to mean "folding, which creates, maintains, or results in the relationship described following such that." Taltech relies on the claims, on the specifications, on dictionary definitions of "such" and "such that," on the opinion of Taltech's expert, Mr. Nienke, and on the Bodle Patent (Taltech's Markman Ex. 8). Esquel asks the Court to construe "folding . . . such that" to mean "folding which creates or results in the relationship described following such that." Esquel relies on the claims and on the specifications.

The parties' dispute centers on Taltech's inclusion of the word "maintains" in its proposed construction. Taltech argues that the relationships described after "such that" are present after folding, but not necessarily as a causal result of the folding. Taltech argues that construing "folding . . . such that" to require a causal relationship narrows the ordinary meaning of the term.

For the reasons outlined above in the discussion of the term "a method . . . comprising the steps," and specifically regarding
the determination that step (e) must come after step (b) in Claim 1 of the 779 Patent, the Court does not rely on the opinion of Taltech's expert, Mr. Nienke, who says that the folding can occur before, or at the same time that, the bonding element is placed along the seam. See Nienke Rebuttal Decl., docket no. 110, P 7 (Taltech's Markman Ex. 11). The bonding element must be present prior to the folding of the first and second garment components.

Taltech submits the "to the extent that" definition of "such that" in support of its "no causation required" construction. See Compact Oxford English Dictionary (Catherine Soanes & Sara Hawker eds., Oxford Univ. Press 3d ed. 2005), available at http://www.askoxford.com/concise_oed/such?view=uk (docket no. 94, Ex. C). Taltech also submits the "of a degree or quality specified" definition of "such that" in support of its construction. See Dictionary.com Definition of "such that", http://dictionary.reference.com/search?q=such%20that (last visited Aug. 19, 2005) (docket no. 94, Ex. D). Taltech has not incorporated these definitions into its proposed construction, and these definitions do not preclude an exclusively causal interpretation of "folding . . . such that."

Esquel argues that Taltech's proposed construction improperly reads "such that" out of the claim. See BBA Nonwovens Simpsonville, Inc. v. Superior Nonwovens, LLC, 303 F.3d 1332, 1344 (Fed. Cir. 2002) (rejecting claim construction that reads a limitation out of the claims). The Court agrees. "Such that" must be given some meaning that connects the action of "folding" to the relationship described following "such that." A causal requirement for "such that" is supported by other claim language that demonstrates a clear connection between an action (other than folding) and the relationship described following "such that." See, e.g., Claim 1(g) of the 779 Patent at 6:50-52 ("applying sufficient heat and pressure to said bonding element . . . such that said adhesive flows . . . ").

Accordingly, the Court adopts Esquel's proposed construction and construes the term "folding . . . such that" to mean "folding, which creates or results in the relationship described following such that."

"such that a user may rest their [sic] tor so thereupon while performing back extensions"

The primary term that Fitness Quest contends requires construction is the single word "torso;" Monti contends the term requires no construction, but argues that if construction is required, his broader proposed construction is more appropriate.

Fitness Quest has not given the Court very much to work with on this proposed construction; presumably, based on its argument at the Markman hearing, Fitness Quest intends to rely on the drawing discussed in Claim 15: Figure 7. Transcript 156.

Figure 7 of the 749 Patent is a drawing of a device on which a person is resting prone -- or on his front -- on the depicted apparatus. Fitness Quest seeks to limit the claim language to the front part of the torso only on the basis of this drawing. This effort is impermissible. A court construing claim terms may not limit its reading of those terms on the strength of a figure depicting a single preferred embodiment. Acumed LLC v. Stryker Corp., 483 F.3d 800, 807 (Fed. Cir. 2007); see also TI Group Auto. Sys. (N. Am.), Inc., v. VDO N. Am., L.L.C., 375 F.3d 1126, 1136 (Fed. Cir. 2004). Rather, "a patentee is entitled to a definition that encompasses all consistent meanings" of the term. TI Group, 375 F.3d at 1136.

"All consistent meanings" of the term "torso" include the back as well as the front of the trunk of the body. In the absence of an express statement in the 749 Patent that "torso" bears the constricted meaning proposed by Fitness Quest, the proposed limitation is not proper. "Claims of a patent may only be limited to a preferred embodiment by the express declaration of the patentee, and there is no such declaration here," Playtex Prods., Inc., v. Procter & Gamble Co., 400 F.3d 901, 908 (Fed. Cir. 2005) (citation omitted). The term "torso" therefore does not require construction.

Fitness Quest's presentation on the question of "back extensions" including only prone (face-down) back extension exercises was brief in the extreme at the hearing in this matter and seems to rest exclusively on the preferred embodiment, as reflected in Figure 7, showing a human figure, resting prone on the embodiment of the invention proposed in that Figure. Fitness Quest contends that the embodiment that the claim teaches is a prone or face-down back extension, thereby apparently arguing that this precludes an embodiment in which supine or other non-prone back extensions could be performed. See Transcript 73. Monti's response was succinct: "If the inventor had intended Claim 15 to be referring to only prone back
extensions, he would have added the word prone." Transcript 78. He didn't. **No construction of this term is required.**

F. Such that each one of the plurality of expansion boards inserted into a corresponding one of said expansion connectors

1. Parties' positions

The parties dispute whether this phrase requires that there actually be expansion boards inserted into the expansion connectors. Tulip contends that this phrase should be interpreted as meaning that "connectors on the riser card can accommodate expansion cards and not that there must be expansion cards inserted into the expansion connectors." 103 Dell argues that "the phrase requires the presence of two or more expansion boards inserted into corresponding expansion connectors on the riser card." 104

--- Footnotes ---

103 D.I. 308 at 6-7.

104 Id. at 11.

--- End Footnotes ---

The complete element of the '621 claims in which this phrase appears reads:

The riser card having a predetermined number of expansion positions thereon, each of said positions having at least one expansion connector associated therewith so as to form a plurality of expansion connectors located on the riser card such that a plurality of expansion boards can be simultaneously mated through said expansion connectors to said riser card, said one expansion connector being either an ISA (industry standard architecture) or a PCI (peripheral connect interface) type connector so as to respectively accommodate an ISA or PCI type expansion board, all of the expansion connectors being horizontally oriented and successively arranged in a parallel fashion one above another, and said riser card being oriented with respect to the motherboard such that each one of the plurality of expansion boards inserted into a corresponding one of said expansion connectors is oriented in a direction substantially parallel to a horizontal plane of the motherboard and extends inward from a vicinity of the side edge towards a central portion of the motherboard. 105

--- Footnotes ---

105 '621 at 6:7-26 (claim 1); Id. at 6:46-65 (claim 2).

--- End Footnotes ---

Tulip argues the disputed phrase describes how expansion boards must be oriented when they are inserted into the riser card, not that there must must be at least two expansion boards inserted into the riser card for there to be infringement. Tulip contends the statement that "expansion connectors located on the riser card such that a plurality of expansion boards can be simultaneously mated through said expansion connectors to said riser card, said one expansion connector being either an ISA (industry standard architecture) or a PCI (peripheral connect interface) type connector so as to respectively accommodate an ISA or PCI type expansion board, all of the expansion connectors being horizontally oriented and successively arranged in a parallel fashion one above another, and said riser card being oriented with respect to the motherboard such that each one of the plurality of expansion boards inserted into a corresponding one of said expansion connectors is oriented in a direction substantially parallel to a horizontal plane of the motherboard …." 107 Tulip asserts that the use of "such that" describes the effect of the riser card orientation with respect to the motherboard. When a computer is configured in accordance with the claimed invention, an expansion board will extend toward the center of the motherboard and be oriented parallel to the motherboard. Tulip argues that the claims do not recite a requirement that expansion boards be inserted into the riser card, but merely that expansion boards may be inserted and if they are, they extend inward over the motherboard. Tulip maintains that the specification, drawings, and prosecution history also support its proposed construction.
Tulip's invention is described in the '621 patent as:

relating to a motherboard for a computer of the AT type, comprising a connector for a [riser] card to be arranged vertically on the plane of the motherboard and a riser card arranged in that connector, said riser card having a predetermined number of positions for expansion cards and comprising a number of connectors, substantially arranged in a row parallel above each other, for such expansion cards, while the plane of an expansion card, when it is arranged in a connector of the [riser] card, extends substantially parallel to the plane of the motherboard. 108

Tulip notes that the italicized language does not indicate a requirement that expansion boards be inserted in the riser card. Tulip also points to specification language referencing removal of expansion cards to support its position that the invention does not require the presence of expansion cards. The specification recites that “when arranging and removing expansion cards, a relatively large force must be exerted.” 109 Tulip characterizes Figure 4 of the '621 patent as showing a preferred embodiment of the invention which illustrates a computer with a riser card inserted into the motherboard with no expansion boards inserted into the riser card. Tulip maintains that it is rarely proper to construe claims to exclude a preferred embodiment of the invention being claimed. 110 Finally, Tulip maintains that the prosecution history supports its proposed construction. When addressing the examiner's reference to the Lam patent, Tulip notes that it did not distinguish its invention by arguing that its invention had at least two expansion boards inserted into a riser card. Tulip argued that its invention was distinguishable from Lam because the Lam patent taught a riser card with only one expansion connector and Tulip's invention taught a riser card having a plurality of expansion connectors.

Dell argues that the plain language of claims 1 and 2 require the insertion of two or more expansion boards in corresponding expansion connectors on the riser card; "each one of the plurality of expansion boards inserted into a corresponding one of said expansion connectors … extends inward …." 111 Dell contends that the specification also supports its proposed construction as it describes impeded air flow over expansion boards resulting from riser cards in earlier computers being located in the middle of the motherboard as a problem addressed by Tulip's invention. The '621 patent purportedly solved this problem by placing the riser card on the side edge of the motherboard so that air "can flow freely over the motherboard and between the expansion cards." 112 According to Dell, Tulip's proposed construction would not achieve one of the described advantages of the '621 patent and, therefore, is incorrect.

110 See Interactive Gift Express, Inc. v. Compuserve, Inc., 256 F.3d 1323, 1343 (Fed. Cir. 2001) (stating that a proposed construction in that case "would not read on the preferred embodiment, and therefore would rarely, if ever [be] correct and would require highly persuasive evidentiary support." (quoting Vitronics, 90 F.3d at 1583; Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1550 (Fed. Cir. 1996) ([A] claim interpretation that would exclude the inventor's device is rarely the correct interpretation; such an interpretation requires highly persuasive evidentiary support ….")).

111 '621 at 6:21-25 (claim 1); Id. at 6:60-64 (claim 2) (emphasis added).
Dell also points to characterizations made by Tulip during prosecution describing its solution for the cooling problem. Where, in distinguishing its claimed invention over the Harwer patent, Tulip described its invention as "teaching that the riser card should be located along an edge of the motherboard with expansion boards connected to the card" 113 as distinguished from the Harwer patent teaching a form factor that suffered from "rather impeded air circulation caused by a centrally located riser card, [and] the proximity of the components from both cards increases the heat build-up between these [expansion] cards, which ultimately reduces their reliability." 114 Dell contends that these statements demonstrate an affirmative characterization of Tulip's claimed invention as requiring two or more expansion boards inserted into corresponding expansion connectors on the riser card.

Dell also argues that Figure 4 does not support Tulip's proposed construction. The purpose of that figure, Dell contends, is to illustrate the computer case for the claimed motherboard. The description of Figure 4 states that it "shows a perspective view of a case for a personal desktop computer of the AT type with a motherboard according to the invention." 115 Dell maintains that Figure 4's illustration of a computer case is directed towards claims 3 and 6, not at issue here, and does not include all of the elements of the claimed invention of claims 1 and 2. Dell contends that the description of Figure 3 also supports its proposed construction. Figure 3 is described as "showing a perspective view of a riser card on which connectors and expansion cards are arranged in the manner of the invention." 116

The court should reject Tulip's proposed construction because, Dell contends, the requirement that a plurality of expansion boards be inserted into the riser card is described as part of the invention in the specification, included in the claim language, and asserted as a basis for several advantages purportedly achieved by the invention.

2. Court's construction

The claim language supports Tulip's contention that the insertion of expansion boards is permissive, not required, to practice the inventions recited in claims 1 and 2 of the '621 patent. The elements of those claims are: a motherboard, a mating connector for a riser card, a riser card having expansion connectors, and a particular configuration of those expansion connectors on the riser card. Focusing on the riser card, that card must have expansion connectors arranged thereon to fall within the scope of the claims. The claim language does not indicate, however, that expansion boards must be inserted into those expansion connectors to practice the invention.

The claim element which refers to expansion boards uses permissive language with regard to the presence of expansion boards and provides the antecedent basis for the final reference in that element to expansion boards. It recites, "expansion connectors [are] located on the riser card such that a plurality of expansion boards can be simultaneously mated through said expansion connectors to said riser card." 117 That claim element continues with a description of the types of expansion
connectors that are to be on the riser card (ISA or PCI connectors) and the orientation of those connectors relative to the riser card and each other. The claim element concludes by describing the orientation of expansion boards inserted into the riser card relative to the motherboard, "said riser card being oriented with respect to the motherboard such that each one of the plurality of expansion boards inserted into a corresponding one of said expansion connectors is oriented in a direction substantially parallel to a horizontal plane of the motherboard." 118 Dell would have the court consider the last quotation in isolation and construe that language as a requirement that expansion boards be inserted. The court will not take such a myopic view of the language of the claims. The antecedent basis for "the plurality of expansion boards inserted …" contains permissive language, "a plurality of expansion boards can be simultaneously mated …" Reading the claim element as a whole, one of ordinary skill would understand that expansion boards can be inserted into the expansion connectors located on the riser card and, if they are, the language on which Dell focuses describes the orientation of those inserted expansion boards relative to the motherboard. Accepting Dell's proposed construction would effectively rewrite the claim language to read "a plurality of expansion boards are simultaneously mated through said expansion connectors to said riser card." The court will not accept the invitation to so limit the claims at issue absent some clear intrinsic evidence supporting such limitation. An examination of the specification and drawings of the '621 patent, however, does not contradict the unambiguous meaning of the claim language.

The specification begins by describing the invention as relating to:

... a motherboard for a computer … comprising a connector for a [riser] card … and a riser card arranged in that connector … having … expansion positions for expansion cards and comprising a number of connectors … for such expansion cards, while the plane of an expansion card, when it is arranged in a connector … extends substantially parallel to the plane of the motherboard. 119

The court agrees with Tulip that this language does not indicate a requirement that expansion cards be inserted into the riser card. The specification reference to "arranging and removing expansion cards" 120 is also supports Tulip's position. That language contemplates practicing Tulip's invention without expansion boards (the inventor chose to refer to "removing," not "replacing," expansion boards) and indicates the discretionary nature of inserting expansion boards in the claimed invention.

Dell is correct that one of the asserted benefits of the claimed invention (unimpeded airflow across expansion boards) would not be achieved if the disputed phrase is interpreted as not requiring that two or more expansion cards be inserted into the riser card. That fact, however, does not mandate acceptance of Dell's proposed construction. The specification notes that other benefits are obtained when the riser card connector and riser card are moved from a central location to a side location. These benefits include: an increased area on the motherboard permitting larger components to be mounted on the motherboard, increased ease of connecting components on the motherboard when the obstruction to linking tracks from the terminals associated with a centrally located riser card connector are removed, and unimpeded airflow across the entire motherboard and its associated components. All of these benefits are still achieved while still permitting the manufacturer or user of the invention the option of achieving the additional benefits described in the specification if the decision is made to insert expansion boards into the riser card.
The '621 patent's drawings do not require that expansion boards be inserted into the riser card. Figure 4 is described as "showing a perspective view of a case for a personal desktop computer of the AT type with a motherboard according to the invention." 121 That figure (reproduced below) shows the motherboard 41 and the riser card 43 with no expansion boards inserted. Even if Dell is correct and this figure pertains to the computer case to which dependent claims 3 and 6 claims (not at issue in this case) are directed, the figure is described as depicting a computer case "with a motherboard according to the invention." Claim 3 depends from claim 2 and, therefore, includes all of the limitations of claim 2. Claim 6 depends from claim 4 and includes all of the limitations of claim 4. Claim 4 recites the same disputed phrase and has the same permissive antecedent phrase, "a plurality of expansion boards can be simultaneously mated," as is recited in claims 1 and 2. Furthermore, inclusion of expansion boards inserted into the riser card in Figure 4 would not have obstructed the view of the claimed computer case. Even if the court were to accept Dell's contention that Figure 4 is only representative of the computer case covered by claims 3 and 6, neither the drawing nor description of Figure 3 (reproduced below), cited by Dell, compel the court to ignore the unambiguous claim language and accept Dell's proposed construction.

[SEE FIG.4 IN ORIGINAL]

As Dell notes, the brief description of the drawings describes Figure 3 as "showing a perspective view of a riser card on which connectors and expansion boards are arranged in the manner of the invention." 122 The detailed description of that figure includes permissive language when describing Figure 3 as "showing a perspective view which shows in what way an ISA expansion card 35 and a PCI expansion card 37 can be placed in their respective connectors 34 and 36." 123 The figure itself shows how the expansion boards can be inserted into the riser card, it does not show those boards already inserted. This is apparent from the arrows on each board showing the direction of insertion of expansion boards should it be determined by a manufacturer or user that their specific needs require expansion boards to be inserted. It is also clear that the expansion boards depicted in Figure 3 have not yet been inserted by observing that the tops of the mounting brackets on the ends of the expansion boards are not flush with the edge of the computer chassis and that the bottom of the lower expansion card's mounting bracket has not closed off the opening of the expansion slot in the computer chassis as would be the case after the boards are inserted in the riser card. Nothing in the specification language or the drawings, therefore, requires the court to accept the limitation suggested by Dell. Finally, the prosecution history does not establish that Tulip distinguished its invention from prior art based on the presence of two or more expansion boards inserted into the riser card.

[SEE FIG. 3 IN ORIGINAL]
problems inherent in the Harwer invention. This court has determined that Tulip's arguments during prosecution served to limit the personal computer covered by the patent to personal computers other than notebook computers. Because Tulip did not seek to avoid the obviousness rejection by arguing that its claims required that expansion boards be inserted into the riser card, it would not be proper for this court impose that limitation.

Since it is clear that the claim language does not require that expansion boards be inserted into the riser card, and because the specification and prosecution history does not compel a contrary determination, the court construes "such that each one of the plurality of expansion boards inserted into a corresponding one of said expansion connectors" to mean that connectors on the riser card can accommodate expansion boards but there is no requirement that expansion boards be inserted into those connectors.

H. Claim language to be construed from Claims 3 and 6 -- "an elongated hollow support for receiving said shoulder of said sheathing in an abutting relationship such that the end of said tube is inserted into said support and said outer diameter of said sheathing and said support are substantially the same at said shoulder" -- col. 4, ll. 61-66; col. 6, ll. 63-68

HEN contends that this claim language does not require any construction and that it should be given its plain and ordinary meaning. (HEN CC Br. at 31.) HEN argues that there is no reason to ignore the heavy presumption that claim terms should be given their plain and ordinary meaning. On the other hand, Minco proposes to construe the terms "the end of said tube is inserted into said support" to mean that "the electrically conductive tube contacts and is force-fit into the interior of the hollow support tube such that the hollow support tube telescopes over the conductive tube to hold the conductive tube in place." (Minco CC Br. at 50.) We agree with HEN that this claim language should be given its plain and ordinary meaning and does not require any construction. In addition, we reject each of Minco's arguments pertaining to its proposed construction.

Minco relies on the patent specification which states, "To facilitate immersing the probe into the molten metal, a support is provided in the form of a paperboard tube 16, which is force-fit over the tube numeral 1." (Minco Ex. A., col. 3, ll. 6-10.) The specification also states, "An elongated hollow support tube is telescopically coupled to the other end of the tube for supporting the tube and the sheath during immersion into a bath of molten metal." (Minco Ex. A., col. 2 ll. 13-14.) Minco also notes that the only figure in the patent specification shows the conductive tube inserted into the paper tube, in direct contact, force fit and telescopically coupled. Minco's proposed construction requests us to import limitations found only in the specification, and not in the claims themselves. This would be improper. See Electro Med. Sys., 34 F.3d at 1054 (stating that a court cannot add limitations appearing only in the specification). Furthermore, Minco's reliance on what it claims is the only embodiment in the patent is misplaced as the Federal Circuit has repeatedly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment. See Phillips, 415 F.3d at 1323.

Minco also points to the prosecution history to support its proposed construction. Minco claims that HEN disclosed to the patent examiner U.S. Patent No. 4,342,633 ("the '633 patent"), which contains an alternative plastic connector, ceramic housing support, and electrical connector system. Minco asserts that HEN never made any attempt to obtain coverage for the electrical connector/support design disclosed in the '633 patent, and argues that by disclosing the '633 patent to the examiner but failing to argue that such a design was patentable, HEN deprived the examiner of the opportunity to consider whether this alternative electrical connector/support design was a permissible construction of the '736 claim language. Therefore, according to Minco, HEN cannot now claim that the prior art disclosed by the '633 patent is a permissible construction of the '736 patent. Minco offers no case law to support this argument. More importantly, this prosecution history that Minco urges us to use to limit the construction of the claim in no way constitutes a clear, unambiguous disavowal of claim coverage. Consequently, we reject Minco's argument that the prosecution history supports its proposed construction.
II. A flattened surface adjacent to said one or more buttons . . . such that the user's ring finger receives support from the flattened surface (Claims 18-21)

The plaintiff's proposed definition is "a substantially flat surface on the right side of the mouse." The defendant criticizes this definition as incomplete because it would include a totally vertical surface which would be inconsistent with the purpose of the flattened surface. The defendant further argues that a wholly vertical surface is precluded by the plaintiff's representations to the Patent and Trade Office ("PTO") during the prosecution of the patent. See JA 87 (stating that the Kaneko mouse's recessed wall cannot support the user's thumb because wall is totally vertical).

The Court is persuaded by the defendant's argument. During the prosecution, the plaintiff distinguished its invention from the prior art, specifically the Kaneko mouse, by explaining that the Kaneko mouse's recessed front wall could not support the user's thumb because it was totally vertical. This representation precludes the plaintiff from arguing here that the right side wall of the 683 patent could be totally vertical because the language of the claim itself requires the side wall to provide support to the user's ring finger. See Southwall Tech., Inc., 54 F.3d at 1576. The Court will adopt the definition of "a surface that is sufficiently flat, wide, and horizontal to support a user's ring finger without the finger touching the mouse button."

3996

3. Interpretation of "Comfortably Grasped"

The language of Claim 1 of the '277 patent requires "sufficient clearance for a user's hands to comfortably grasp the handle structure." Norseman argues that proper construction of "comfortably grasped" requires a handle that requires "total clearance" above and below the handle bar. Motion, at 21.

Norseman asserts that the prosecution history of the '277 patent makes clear that a "comfortable grasp" requires that the handle be completely free of all obstructions. Specifically, Norseman points to the Patent and Trademark Office ("PTO") twice rejecting Rehrig's application for obviousness in view of prior art patents. One such patent was U.S. Patent No. 5,487,487 ("the Hammett patent") which disclosed a handle connected to the floor by a column which met the handle at its midpoint. Rehrig's response to the rejection distinguished the Hammett patent because the handle structure recited in Rehrig's application is "like a bar with total clearance above and below the bar ... This bar-type is significantly different structurally and functionally from the 'handles' of Hammett." Speranza Decl., Ex. 5, at 3-5. Further, Rehrig argued that its own handle allowed a user to "grasp the entire periphery of the handle."

Rehrig contends that the attempt to distinguish the Hammett patent was based upon the fact that the Hammett patent could only be grasped by a user with the user's palms up whereas Rehrig's crate could also be grasped in the "palms down" position. However, the crux of Rehrig's argument to the Examiner was that the Rehrig crate allowed for a "true handle structure that provides clearance on top and bottom for a user's hands to grasp the entire periphery of the handle." The relevant definition of "periphery" is "the external boundary or surface of a body." 5 Rehrig's argument therefore suggests that Rehrig crate is distinguishable from the subject matter of the Hammett patent because the entire surface area of the handle is able to be grasped by a user for the former, but not the latter due to the column bisecting its handle.

Arguments made during prosecution of a patent application to overcome prior art may narrow Claim interpretations. See Rheox. Inc. v. Entact. Inc., 276 F.3d 1319, 1325 (Fed. Cir. 2002); Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution."). The Court finds that Rehrig is estopped from asserting that handle structures containing some obstruction or incomplete clearance are within the subject matter of the '277 patent.

The Court accordingly construes this phrase as limited to handles that provide the user's hand absolute clearance.
will now analyze whether the NPL 403 infringes the Claims at issue in the '843 and '277 patents.

5. "Said deforming step . . . radially compressing the mat to substantially reduce its thickness and to apply sufficient radial pressure against the substrate to hold the substrate in the body." Consistent with the claim language and its ordinary meaning, 10 and the specification, 11 the court construes "said deforming step . . . radially compressing the mat to substantially reduce its thickness and to apply sufficient radial pressure against the substrate to hold the substrate in the body" to mean "the deforming step and the mat alone supply enough pressure to hold the substrate in the body for its intended use."

13. Sufficient Space

The next term for construction is "sufficient space" as it appears in claim 33 of the RE '439 patent. The Plaintiffs contend that the term means "enough room in the groove so that the panels can be moved relative to one another along their joined edges." (Pls.' Open Br. 33.) Pergo contends that it means "the amount of space between the locking groove and the locking element is enough to allow for the free movement of the joined panels such that the panels can (i) slide easily relative to one another along their joined edges and (ii) can be disassembled by angular rotation of one panel about the other joined edge." (Unilin's Open. Br. 33-34.)

Claim 33 of the RE '439 patent provides:

A system for providing a joint between adjacent building panels, comprising:

...
The Plaintiffs maintain that the Court should construe sufficient space as not including play and construe the limitation based on its plain meaning. However, this Court has determined that play is inherent in the RE '439 patent claims. In large part, Pergo's proposed construction is consistent with the claim language. However, there is no basis for reading "free" movement into the definition of the term. The Court defines "sufficient space" in claim 33 of the RE '439 patent as "the amount of space between the locking groove and the locking element is enough to allow for the movement of the joined panels such that the panels can (i) slide relative to one another along their joined edges and (ii) can be disassembled by angular rotation of one panel about the other joined edge."

The Court defines "sufficient space" in claim 33 of the RE '439 patent as "the amount of space between the locking groove and the locking element is enough to allow for the movement of the joined panels such that the panels can (i) slide relative to one another along their joined edges and (ii) can be disassembled by angular rotation of one panel about the other joined edge."

3. "Shell having a hardness sufficient to maintain the shape of the grip." Used Claim 1.

Kwitek suggests "a structure or framework having an inner and outer surface and that has a level of firmness capable of keeping or preserving the grip's shape." Pilot proposes "a unitary hard casing with adequate firmness to keep the grip in its originally designed shape while being grasped with hand or finger pressure appropriate for writing."

Both proposals describe something that is firm enough to keep the shape of the grip. This comes straight from the claim itself. '190 patent, col. 8, l. 66-col. 9, l. 1. Obviously, in the context of a pen grip the inventor was not talking about the shell of this soft grip being able to maintain its shape under the crushing force of a vice. The specification states that the shell may be constructed from a variety of elastomers. '190 patent, col. 3, ll. 48-50. In the preferred embodiment, the shell will have a Shore A hardness of 20-55. '190 patent, col. 3, ll. 51-52. This includes the high end of range described earlier in the specification as being "ultra-soft." '190 patent, col. 3, ll. 13. These statements indicate that the shell can be fairly soft.

But it is clear that the shell has to maintain the shape of the grip when fingers hold the implement for writing. Of course, this does not imply that the viscoelastic hand/finger surface will be unyielding to pressure from fingers.

The real debate seems to be Pilot's attempt to add the word "unitary" to the definition. It is true that the claim and specification always use the singular in referring to the shell as well as to the grip. For example:

"a longitudinally extending, tubular shell . . . "'190 patent, col. 8, l. 66;

"The shell has an inner surface . . . and an outer surface. . . "'190 patent, col. 9, ll. 1-2;

"the outer surface of the tubular shell; the shell further . . . ."'190 patent, col. 9, ll. 3-4;

"The shell may be constructed . . . ."'190 patent, col. 3, l. 48; and

"a shell 112 shaped and dimensioned to fit about the grip . . . ."'190 patent, col. 4, ll. 25-26.

But it is difficult to see what adding the word "unitary" to the definition will do. A shell might be made of more than one piece, so long as it fulfilled the other requirements of the claim language and was not disclaimed or disavowed in the specification or prosecution history. For example, the court can imagine a tube, split longitudinally, but constructed so as to keep its shape when squeezed. Pilot certainly did not have anyone skilled in the art present who could explain why this would be physically impossible, or not be apparent to another skilled artisan.

There is no authority for the addition of superfluous limitations in claim construction, even if they may later be useful to the infringement analysis of a party. This is not to say that any grouping of disjointed pieces will be considered "a" shell or "the" shell. Pilot will be free to argue that two or more separate pieces are not "a" shell. But claim construction does not consist of attempting to anticipate the variety of accused devices which may be presented and then to predict the infringement arguments that might arise from the fertile mind of learned counsel. The court will define this term as follows:

"Shell having a hardness sufficient to maintain the shape of the grip" means "a structure that is firm enough to maintain the shape of the grip while the writing implement is used for writing."
The principal disputed elements of Claims 1 and 17 are in the portion set forth below. To aid understanding, the Court has provided its own emphasis to some of the language:

"said layer of foam being sufficiently resiliently compressible to [1] allow the layer of foam to be pressed manually against the painted surface to compress the portions of the layer of foam toward the rear surface of the layer of foam and cause the parts of the front surface of the layer of foam defined by both the projecting portions and the recessed portions to generally conform to the painted surface and press the glazing or compounding material into engagement with the painted - surface for efficient removal of imperfections, and [2] subsequently to allow the layer of foam to be manually pressed against the painted surface with a lesser force only sufficient to compress parts of the projecting portions of the layer of foam to complete polishing of the painted surface."

The meaning of this claim is discernible from the language of the claim alone, although it is complicated phraseology. "Resiliently compressible" means that the foam will resume its shape after it is compressed. "Sufficiently resiliently compressible" means that [1] the foam must be soft enough to be able to perform the function of allowing the convolutions (projections) to compress enough so that both the projections and the flat portion will "generally conform to the painted surface" and cause "efficient removal of imperfections", and [2] it must be hard enough so that when a lesser force is used, only the projections do the polishing. A person operating a buffer would be able to vary the pressure on the pad in such a way as to choose to cause only the tips of the pad to touch the surface, or to cause all or virtually all of the pad face to come in contact with the surface being polished, when operating the buffer in the normal manner done in body shops. Put the other way around, a pad would not infringe if the foam were so hard that the projections could not be compressed to the painted surface with the flat portion for efficient cleaning under normal pressure, and it would not infringe if the foam were so soft that the projections were compressed to the painted surface with the flat portion even when a lesser force is used.

This interpretation seems required by the plain meaning of the words in the claim. The description of the invention and the manner of use of the invention confirm this interpretation. In column 3, lines 1 through 19, the inventor theorizes that advantages of the invention are achieved in some instances by "the different amounts of compression of the projecting and recessed portions" of the pad when the entire face generally conforms to the surface being polished, and that other advantages are achieved "when only the projecting portions are in contact with the painted surface." In addition, the specification describes the use of the invention involving an initial pressing down so the projections and the valleys both generally conform to the surface, and subsequently reducing the force so that only the projections are applied to the surface. Column 8, lines 17-64, and FIGS. 9 and 10.

b. "said sealing portion being sufficiently soft to seal against an air flow tube, to form a radial seal against the air flow tube and cylindrical inner support"

The phrase "said sealing portion being sufficiently soft to seal against an air flow tube, to form a radial seal against the air flow tube and cylindrical inner support" appears in claim 1 of the '366 Patent. Donaldson asserts this phrase has a meaning readily understood by one of skill in the art and construction of the language is not necessary. Baldwin asserts that the phrase should be construed as "a sealing portion of the first end cap is made of polymeric material sufficiently soft such that it is radially compressed between and against the air flow tube and cylindrical inner support."

First, Baldwin proposes that the "air flow tube" be construed as a required functional component of this claim. In support, Baldwin argues that the claim language "to seal against an air flow tube" requires that the portion of the first end cap form a radial seal with the air flow tube, and that such limitation can only be met if the air flow tube is present. In contrast, Donaldson contends that the air flow tube is a work-piece or an environmental element that is not part of the claim simply because it touches the filter in use.

Looking first to the language of the claim, it is apparent that the air flow tube is not the subject of the clause. The text of the
claim does not mention an air flow tube positively as an element of the claim. Instead, the air flow tube is mentioned to explain how the air filter seals when installed in an assembly and is part of the environment in which the claimed air filter operates. See SDS USA, Inc. v. Ken Specialties, Inc., 107 F. Supp. 2d 574, 593 (D.N.J. 2000). Specifically, the claim language discusses the air flow tube using words indicating that it is an environmental element. For example, the claim states: "said sealing portion being sufficiently soft to seal against an air flow tube to form a radial seal against the air flow tube, when the filter element is mounted on an air flow tube" (emphasis added). 15

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

15 Claim 1 of the '009 Patent reads in part: "said sealing portion being oriented to seal around, and against, an appropriately sized air flow tube, whenever the filter element is operatively positioned with the airflow tube projecting through said air inlet aperture" (emphasis added).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The Court recognizes that when a claim includes detailed structural language on another element, it can become a claim limitation. For example, in Bicon, the Federal Circuit affirmed the construction of a claim term in a patent for an apparatus used with dental implants. 441 F.3d at 952. The claim at issue in Bicon recited in part "[a]n emergence cuff member for use in preserving the interdental papilla during the procedure of placing an abutment on a root member implanted in the . . . bone of a patient." Id. at 949. The district court construed the claim to include both the "emergence cuff member" and an "abutment." Id. at 952. In affirming, the Federal Circuit noted that:

[d]espite the fact that the claim begins with a reference to the emergence cuff alone, the full text of the claim, read in the context of the entire patent, indicates that the claimed invention is the combination of the emergence cuff and the abutment, operating together in the fashion recited in the claim and described in the specification.

Id. at 952. Here, however, there is no detailed or significant reference in the claim to the air flow tube. 16 Instead, reference to the air flow tube is necessary to describe the invention, but the air flow tube is not an element of the claim. See SDS, 107 F. Supp. 2d at 593.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

16 In contrast, in Bicon, the Federal Circuit noted that the claim at issue included a detailed description of the abutment's physical characteristics (i.e., the abutment has "a frusto-spherical basal surface portion and a conical surface portion having a selected height extending therefrom") and defined the emergence cuff in a way that depends on those characteristics (i.e., "the internal bore of the emergence cuff has 'a taper generally matching that of the conical surface portion of the abutment'" and "the distance between the first and second ends [of the emergence cuff is] less than the height of the conical surface' of the abutment"). 441 F.3d at 950 ("Together, the preamble and the body of the claim contain a detailed description of the features of the abutment used in connection with the emergence cuff.").

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Second, Baldwin argues that the overall limitation in this claim should be construed to mean "the sealing portion of the first end cap is made of polymeric material sufficiently soft such that it is radially compressed between and against the air flow tube and cylindrical inner support." In support, Baldwin points to the following language in the specification:

When assembled, inlet tube 14 extends into aperture 28 in end cap 23. At least in this location, end cap 23 is preferably formed of a soft compressible material. . . For the particular arrangement shown in FIGS. 1-7, material at region 40 is compressed between and against both inlet tube 14 and inner support 26; that is, inner support 26 is set sufficiently deeply into end cap 23 that a portion of it is positioned behind compressible region 40, to provide support. Thus, a good seal is effected.

'366 Patent, col. 6, ll. 29-56.

The claim language itself requires that the "sealing portion" be made of polymeric material and that it be "sufficiently soft to
seal against an air flow tube, to form a radial seal against the air flow tube, when the filter is mounted on an air flow tube." The claim language does not, however, require a particular type of radial seal. Further, the Court determines that the intrinsic evidence does not support the additional limitation added by the "radially compressed" language proposed by Baldwin. Although the patent specification does discuss the radial sealing between the filter element end caps and a housing and provides that the sealing can involve compression, this type of sealing is an example. The language of the claim is not limited to a particular form of contact. Therefore, the Court declines to import the limitation appearing only in the specification. See Phillips, 415 F.3d at 1323. Accordingly, the Court declines to adopt Baldwin’s proposed construction and does not construe the phrase "said sealing portion being sufficiently soft to seal against an air flow tube, to form a radial seal against the air flow tube and cylindrical inner support."

The Court finds that the proposed constructions in the R&R for "suitable for installation by the average consumer" and "can be installed by the average consumer" are appropriate when the new construction of "average consumer" is substituted therein. Thus, those terms would be construed as follows:

1) "suitable for installation by the average consumer" to mean capable of being installed by an individual that purchases supplies for a home improvement task from a retail outlet and performs the home improvement task himself or herself, regardless of whether the individual has any training in that task;

2) "can be installed by the average consumer" to mean capable of being installed by an individual that purchases supplies for a home improvement task from a retail outlet and performs the home improvement task himself or herself, regardless of whether the individual has any training in that task.

There is only one point of contention between the parties regarding anticipation of independent claims 9, 21, and 22 of the '276 patent: the use of "sunglasses" in the preamble of all these claims and use of "for use in sports and casual activities" in the preamble of Claims 9 and 21. This contention also extends to the anticipation of dependent claims 11, 15, 18, 19, and 20. Protective has clearly shown that the rest of the limitations recited in the claims were anticipated by the '688 patent. Pfriem Dec., PP 10-41; id., Ex. B. Panoptx does not challenge this demonstration and thus the court is convinced that the rest of the limitations were anticipated by the '688 patent.

The court refuses to read in "for use in both sports and casual activities" into the preamble of Claim 22. It is clear from the patent specification that the patentee could have added such a phrase into whichever claims he wanted and deliberately chose not to add it to Claim 22. Furthermore, the court will not re-write claims in order to preserve their validity. See Pfizer, Inc. v. Ranbaxy Laboratories Ltd., 457 F.3d 1284, 1292 (Fed. Cir. 2006).

Whether the preamble constitutes a limitation to a claim is a matter of claim construction, and hence, a matter of law. Catalina Mkt'g Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 807 (Fed. Cir. 2002). A preamble generally limits the claimed invention if it "recites essential structure or steps, or if it is necessary to give life, meaning, and vitality to the claim." Id. at 808 (internal quotations omitted). For instance, "[w]hen limitations in the body of the claim rely upon and derive antecedent basis from the preamble, then the preamble may act as a necessary component of the claimed invention. On the other hand, if the body of the claim sets out the complete invention, then the language of the preamble may be superfluous." Eaton Corp. v. Rockwell Int'l Corp., 323 F.3d 1332, 1339 (Fed. Cir. 2003) (internal citations and quotations omitted). "Thus, if the preamble helps to determine the scope of the patent claim, then it is construed as part of the claimed invention." NTP, Inc. v. Research In Motion, Ltd., 418 F.3d 1282, 1305 (Fed. Cir. 2005).
The preamble here limits the scope of the claim. The claims only cover sunglasses as opposed to more general eyewear. The claim further teaches a "lens means for protecting a wearer's eyes . . . ." which has been construed above as "lens." '276 patent at 5:59-60. Taking the terms in conjunction and in context with the patent specification, it is clear that the patentee meant protection from the sun in addition to protection from particulate matter. There is some merit to Protective's argument that the body of the claim sets out the complete invention, and thus the language of the preamble may be superfluous. The "sunglass" language, however, was added to the patent in order to distinguish the invention over the prior art. See Opp. Br. at 4; Hong Dec., Ex. B at PRO000204-220. This provides further evidence that the scope of the limitation extends only to sunglasses and not eyewear generally. Finally, the preamble is necessary to give life and meaning to the claim because the patent focuses on the ability of the user of the invention to wear the eyewear for casual purposes independent of whether the user has prescription glasses. '276 patent at 1:64-2:4.

3 The court does not reach the question of invalidity due to inoperability because this motion is directed toward invalidity due to anticipation and/or obviousness. In addition, Panoptx has not had a chance to refute the argument for inoperability. Thus Protective's argument for invalidity due to inoperability is reserved and may be brought at a later time.

C. "Super-Purifying Said Smoke to Reduce Taste Imparting Components Below Thresholds for Imparting Smoke Odor and Taste"

The language of Claim 67, discussed above, is quite similar to the language of Claim 1, which claims "super-purifying said smoke to reduce taste imparting components below thresholds for imparting smoke odor and taste." (Kowalski Patent, Col. 28, at 11-18.) TPI raises similar claim construction arguments here as it raised for Claim 67, once again requesting that numerical values listed in Table 3 be ascribed to the process of "super-purifying" the smoke "below thresholds for imparting smoke odor and taste." (TPI Brief 20). For the reasons discussed above, the Court finds that "super-purifying said smoke to reduce taste imparting components below thresholds for imparting smoke odor and taste" is supported by the disclosures made in the specifications. It will not be numerically limited by the Court.

G. "superimposed in separate printing steps"

The parties' proposed constructions of this disputed phrase are nearly identical. The Plaintiff claims the phrase means "sequentially applying the screened half tone images to create the overprint layer." The Defendant proposes the following similar construction: "printing the screened halftone images sequentially one over the other so that they can combine and blend optically." Thus, the parties effectively agree that the ordinary meaning of the phrase is "sequentially printing the screened half tone images." The Defendant's construction states that the screened halftone images are printed sequentially "one over the other." This additional language is consistent with common meaning of "superimpose," i.e., "to place on or over something else." Webster's College Dictionary at 1106. Although this language is not part of the Plaintiff's proposed construction, the Plaintiff does not seem to object to its inclusion in the construction. (Pl.'s Mem. in Supp. of Mot. for Claim Construction, at 23-24.)

Despite agreeing for the most part on the construction of this phrase, the Plaintiff claims that the Defendant improperly narrows the plain meaning by adding the phrase "so that they can combine and blend optically." As discussed above, this invention uses the process color printing technique to create the overprinting layer. It appears that one skilled in the art would understand that process color is a type of printing "in which dots of one color are overprinted on dots of one or more other colors to produce blends." GATF Encyclopedia at 313. Moreover, this limitation is drawn directly from the language of the specification. When discussing the process color printing technique, the specification states: "The separated images

- 4671 -
are then printed one over the other in transparent ink. When the separated images are superimposed, they combine and blend optically to produce the visual effect of full color with virtually limitless tones and shades." ('647 patent, col. 4, 11. 61-65; 504 patent, col. 5, 11. 34-38) (emphasis added). Therefore, reading the claim term in context, the Court construes "superimposing in separate printing steps" to mean "sequentially printing the screened half tone images one over the other, resulting in the half tone images combining and blending optically."

4006
2. "Electrically Conducting Fluid Supply."

Consistent with the prosecution history, the phrase "electrically conducting fluid supply" shall be construed to mean "a medical container that stores electrically conducting fluid." (D.I. 267, Ex. 10 at 4-5) An example of a medical container is an IV bag. An example of electrically conducting fluid is isotonic saline. (Id.)

4007
1. "supply of coins"

Tidel proposes that the term means "stored coins." FKI proposes the term means "segregated coins by denomination within hoppers." FKI argues the embodiment in the specification requires that all the coins inside the cabinet must be placed into separate bins or hoppers according to denomination. [7:44-56]. FKI is attempting to limit the claim to the preferred embodiment by requiring the coins be segregated. The court, therefore, construes the term "supply of coins" to mean "stored coins."

4008
a. The construction of "a supply of stored gas is provided"

Taking the disputed terms of Claim 16 first, plaintiffs contend that "a supply of stored gas is provided" refers to the environment in which the claimed invention operates. They also assert that interpreting the claim language in light of the specifications impermissibly results in reading limitations from the specifications into the claims. Bauer, on the other hand, contends that the phrase requires that a supply of stored gas is an integral part of the claimed invention.

This court finds that the phrase "supply of stored gas is provided" means in the context of the 455 Patent that such a supply of stored gas is an integral part of the claimed invention. Plaintiff's assertion that the gas supply is merely part of the environment in which the claimed invention operates is belied by both the language of the claims and the specification. In Claim 16, the phrase "a supply of stored gas is provided" appears after the transition phrase "the improvement wherein . . ." This alone indicates that the gas supply is considered a part of the claimed invention. Further, the accompanying specification states that a supply of bulk gas is part of the invention:

The invention apparatus, broadly considered, includes a bulk supply system, 24, a booster system, 26, a booster drive system, 28; a high pressure storage system, 30; a pressure control system, 32; a supplemental gas storage system, 34; a pilot operated gas system, 36; an electrical control system, 38; and a gas injection conduit, 40. Apparatus components 24, 26, 28, 30, 32, 34, 36, 38 and 40 together comprise control means for selectively controlling the gas delivered to the mold with respect to pressure and time. U.S. Patent 5,118,455, col. 5, lines 5-14.

From the above, it is clear that a gas supply is considered to be a part of the claimed invention. It comprises a part of the "control means" which are integral to the claimed invention and are necessary to perform both of the specific functions identified in Claim 16, that of injecting the gas into the mold and that of pressure profiling, ie increasing the pressure in the mold, decreasing it or holding it constant.
Epcon argues that the stored gas supply should not be considered to be a part of the apparatus identified in Claim 16, because it is not required to perform the functions identified in that claim, that is, injecting gas into the mold and then of performing pressure profiling where the gas pressure within the mold is increased, decreased or held approximately constant. Epcon claims that the only apparatus needed to perform these functions is the pressure control system, which is defined to be comprised of regulators 97 and 98 and a relief valve 157.

These devices certainly play a role in these two functions but, equally certainly, they are not sufficient by themselves to accomplish the tasks identified in Claim 16. These components are, for instance, clearly unable to perform the function of injecting gas into the mold, because they lack any source of such gas. Likewise, they cannot, by themselves, act to increase the gas pressure within the mold for the same reason.

Bauer next contends that the supply of stored gas must be pressurized to at least 12,000 psi to allow the gas to be injected into the mold at a pressure that is at all times less than the pressure of the stored gas supply. Plaintiffs concede that the values given in the specification for stored gas pressure uniformly exceed 12,000 psi. However, they argue that these pressures are clearly identified as mere examples of typical pressures and are not, therefore, crucial features of the claimed innovation. They further argue that the specific gas pressures used in the gas storage apparatus are dependent on the requirements of the particular molding process.

In this regard, the points raised by plaintiffs are well taken. There is no basis in the disputed claim language or in the specifications for a conclusion that the values identified for stored gas pressures are anything but exemplary in nature. First, when such values are identified in the specification, they are identified as being exemplary. Second, there is no basis for concluding that the particular values of the gas pressure in the stored gas supply is critical to either the operation of the claimed invention or to its patentability.

However, this is not to say that the gas pressure, or more specifically, the difference between the pressure of the stored gas supply and the pressure at which gas is injected into the mold is totally irrelevant to the issues presented by the Markman proceeding or defendant's motions for summary judgment. This is because the parties also dispute the meaning that should be given to the word "substantially." This term appears in two different contexts: in the first case it is used to describe a value for gas pressure that is held approximately constant over a period of time, as in Claim 2 "the gas pressure in the mold is selectively increased, decreased or held substantially constant." The second context, occurring both in Claim 2 and Claim 16 indicates that the pressure of the gas injected into the mold is substantially below that of the gas in the stored gas supply.

A. "Supply of Stored Gas"

The district court construed the phrase "a supply of stored gas is provided" to mean that such a supply of stored gas is an integral part of the claimed invention. Epcon argues that this phrase is part of the transition in both claims 2 and 16, and is therefore a non-limiting part of the environment for the claim. Epcon argues that the district court erred in finding that the gas supply is an "integrated" component of the apparatus of claim 16. In contrast, Bauer argues that the phrase is not part of the transition of either claim 2 or 16, and the phrase is properly limiting because the specification describes this claim limitation as "an important feature of the invention apparatus."

Contrary to Epcon's characterization, the district court did not find that the stored gas supply is an "integrated" component of the apparatus of claim 16. Instead, the district court found that the stored gas supply is an "integral" part of the claimed invention. The distinction is important.

Integral is defined to mean "components that form a complete unit." The Contractors' Dictionary of Equipment, Tools and Techniques 315 (1st ed. 1995). Integrated is defined to mean "[a] type of design in which two or more basic components or functions are physically, as well as electrically, combined - usually on one chassis, such as an integrated amplifier." Modern Dictionary of Electronics 381 (7th ed. 1999). "Integral" connotes that the stored gas supply is a component part of the claimed invention, as opposed to "integrated," which connotes physical combination. Thus, an infringing apparatus/method must have a stored gas supply as a component part, but it is not required that the gas supply be physically combined on one chassis with all other parts.
The specification of the 455 patent provides further support for our construction. The 455 patent specification states, "the invention apparatus, broadly considered, includes a bulk supply system 24 . . . . Bulk supply system 24 comprises a bulk storage container 42 . . . [which] may comprise, for example, a commercial nitrogen bottle storing nitrogen at a nominal pressure." 455 patent, col. 5, ll. 5-20. "In operation, nitrogen gas is delivered from the bulk supply 24 to the regulator 46 at a stored pressure." Id. at col. 9, ll. 53-54. Thus, according to the intrinsic record the "supply of stored gas" is included in the "invention apparatus, broadly considered," and operates with other components in the claimed method. Nothing in the intrinsic record requires that the supply of stored gas be physically combined on one chassis with the other components of the claimed method or apparatus.

The district court did not err in finding that the "supply of stored gas" is integral, or a component part of the claimed apparatus and process. In method claim 2, the phrase "a supply of stored gas is provided" appears in the preamble. In the apparatus claim 16, the phrase appears after the transition. Since both claims are in Jepson format, the phrase recites elements that define the scope of the claimed invention. See Kegel, 127 F.3d at 1426, 44 U.S.P.Q.2D (BNA) at 1127; Rowe, 112 F.3d at 479, 42 U.S.P.Q.2D (BNA) at 1553.

2. support (claims 2, 4-9, 12, 14)

Fargo - aperture, bore, or other apparatus that can be used to support, detain, carry, or accept insertions of another object

Iris - This is governed by , P 6, and covers apertures extending through the hub, plus equivalents thereof

Iris contends that the word "support" is a means-plus-function limitation and is therefore governed by 35 U.S.C. § 112, P 6, which states that such claims "shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." As such, Iris contends that, as shown in the specification, the "bores" or "apertures" that hold the pins must extend all the way through the hub.

A patentee's use of the word "means" in a claim limitation gives rise to a rebuttable presumption that it is a means-plus-function limitation within the meaning of § 112, P 6. Apex Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1371 (Fed. Cir. 2003). Conversely, when a claim limitation does not include the word "means," there is a rebuttable presumption that § 112, P 6 is inapplicable. Id.; see also Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) (stating that "the presumption flowing from the absence of the term 'means' is a strong one that is not readily overcome."). Here, the claim limitation does not include the word "means," but Iris can rebut the corresponding presumption by demonstrating that the claim term fails to recite sufficiently definite structure, or else recites a function without reciting sufficient structure for performing that function. Apex, 325 F.3d at 1372.

In claims 4, 6, and 9, "supports" are clearly defined as either "bores" or "apertures" in the claims themselves. In claims 2, 5, 7, 8, 12, and 14, however, the word "support" is used without any recitation of a structure. If the word "support" has a reasonably well understood meaning in the art, however, it is not a means-plus-function limitation. Id. The word need not call to mind a single well-defined structure to avoid application of § 112, P 6. Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583 (Fed. Cir. 1996)(holding that "detent mechanism" had a reasonably well understood meaning in the art); Lighting World, 382 F.3d at 1358 ("The fact that more than one structure may be described by that term, or even that the term may encompass a multitude of structures, does not make the term 'connector assembly' any less a name for structure."). Finally, the fact that the disputed term is derived from the function performed does not necessarily indicate that it fails to indicate a structure. Lighting World, 382 F.3d at 1361. In light of these cases, it is clear from reading through the claims that the word "support" is used throughout the patent to denote a structure, not a function. Iris contends that Fargo's definition is too broad, but this is not a reason to hold that the word is a means-plus-function limitation. Id. at 1361-62. The Court therefore adopts Fargo's proposed definition and declines to find that "support" is a means-plus-function limitation.
3. Support/Supporting

Plaintiff's definition of "support" is "to bear the weight of, or hold up." Defendants initially provided a similar dictionary definition from the American Heritage Dictionary, defining "support" as "to bear the weight of . . . [or] to hold in position." The American Heritage Dictionary of the English Language, supra, at 1739.

Defendants now state that Plaintiff's definition of "support" is "an acceptable starting point" but argue for a more complicated definition of "providing an ancillary positioning or strengthening function, including to bear the weight of, especially from below; to hold in position."

Defendants' new definition of "support" attempts to add the limitation that the support is "ancillary." Defendants' reasoning is that they believe the handguard of the '465 Patent requires at least two areas of support, and thus each area of support is only ancillary. Even if this assertion is true, Defendants are clearly attempting to import a limitation from the specification into claim 31.

As used in claim 31 of the '465 Patent, "support" or "supporting" means to bear the weight of, or to hold up either completely or partially.

a. "a support"

The term "support" calls for a structurally rigid, molded structure that serves as a prop, base, foundation, brace or stay for a shift lever and related attachments, and pivotally mounts a transmission shift lever, such that the pivot axis is at a low position on the shifter to provide optimal mechanical advantage and movement to actuate a transmission shift cable.

(2) Support Block

Claims 1, 44, 45, 49-52 of the '988 Patent also uses the phrase "support block." Innovative argues that the court should construe this phrase to mean "a block to support other components" according to its ordinary and customary meaning. Defendants, once again, propose a more narrow definition by seeking to import the specification limits into the purposefully general claim language. Defendants urge the court to construe support block as "a cast generally cubical block having a bushing hole and a shaft hole extending nearly the entire height of the support block" based on the specification. See PI's Markman Br. Ex. E. col. 4 ll. 10-15. For the reasons related in the analysis of the "bushing" term, the court will not limit the claim language by reference to the specification. Therefore, the term "support block" is construed to mean "a block to support other components."

As an initial matter, we agree with the parties that both the handle receipt means and the handle disengagement means limitations should be construed as means-plus-function type limitations pursuant to 35 U.S.C. § 112, ¶ 6. However, the parties dispute whether or not the "support body means" limitation also invokes a means-plus-function § 112, ¶ 6 analysis.

The "support body means" limitation stands alone and does not recite any associated structure. The limitation also does not recite much functional detail. However, the term "support" itself connotes function. Because the "support body means"
limitation uses the phrase "means" and also recites function, without reciting any definite structure, it is appropriate to construe the term as a means-plus-function limitation.

As no other claim construction issues have been raised by the parties, we proceed to analyze the summary judgment ruling of noninfringement.

4015

(a) "a support frame to which the trailer is mounted;"

This term may be defined by the ordinary meaning of the terms as "a skeletal framework or other structure for a towed vehicle."

4016

A. "support layer"

MacDermid proposes to construe the term "support layer" as "a flexible transparent material upon which the photopolymer material is disposed." (MacDermid Responsive Br. at 2.) DuPont proposes the construction "a flexible transparent material that retains or absorbs greater than 80% of actinic radiation." (DuPont Opening Br. at 1.)

DuPont contends that MacDermid made a statement in the prosecution history that the support layer must absorb between 80% and 99% of actinic radiation. (DuPont Opening Br. at 11.) The PTO initially rejected the proposed new claims in the '835 Patent as unpatentable over Kurtz in view of Fan and over Fan in view of Canty. (Id.) DuPont states that in order to overcome this rejection, MacDermid represented to the PTO examiner that "[e]ven if Fan and Kurtz are combined, they do not reveal the claimed invention. . . .[T]hey do not reveal that the substrate should absorb between 80%-99% of the incident backflash actinic radiation or between 85%-95% of the incident backflash radiation." (Id. at 12.) DuPont states that the PTO relied on this statement in withdrawing its rejection of the patent. (Id.) DuPont contends that this statement is of "critical significance" to the Court's construction of "support layer." (DuPont Responsive Br. at 3.) DuPont states that for purposes of construction, MacDermid cannot dismiss the arguments it made to the PTO, and DuPont's construction should prevail. (Id. at 5.)

MacDermid contends that its construction is supported by the specification and the prosecution history. (MacDermid Opening Br. at 8.) The specification states that the "support layer of the photocurable element is preferably formed from a variety of flexible, transparent materials." (Id.) Further, the plain language of the claims states that "the solid photocurable material is disposed on the support layer." (Id.)

MacDermid contends that DuPont's proposed construction improperly narrows the term with its inclusion of an 80% absorption requirement. (MacDermid Responsive Br. at 2.) MacDermid states that this construction lacks support in the intrinsic evidence, contradicts the plain language of the '835 Patent, and that there is no claim language necessitating an 80% absorption requirement. (Id.; Tr. at 17.) It contends that DuPont improperly focuses on a single statement in the prosecution history that it takes out of context. (MacDermid Responsive Br. at 2-3.) MacDermid acknowledges that some claims in the '835 Patent do, in fact, contain a percentage limitation, but other claims contain no such limitation. (Id. at 3.) It states that claims should be considered in the context of other claims in the patent. (Id.) Thus, it contends that "support layer" should be construed the same way for all claims. (Id. at 4.)

MacDermid further argues that under the doctrine of claim differentiation, a limitation added to a dependent claim creates a presumption that the added limitation does not exist in the independent claim. (Id.) MacDermid states that dependent claims 16 and 17 contain a percentage limitation, thereby creating the presumption that the limitation does not apply to the independent claim 13. (Id. at 4-5.) MacDermid further argues that the specification does not support DuPont's construction. (Id. at 5.) The specification states that the support layer must absorb "at least some actinic radiation," but does not contain a percentage limitation. (Id. at 6.)
Responding to DuPont's assertion regarding the applicant's statement during the prosecution history, MacDermid states that the disputed statement did not constitute a disavowal of claim scope. (Id. at 7-8.) MacDermid contends that the applicant distinguished the '835 Patent from Kurtz and Fan by noting that those patents did not disclose that the support layer should absorb UV radiation at all, not that those patents merely disclosed absorption in a lesser amount. (Id. at 9; Tr. at 22.) The applicant stated the Kurtz and Fan did not "reveal that the substrate should absorb U.V. radiation." (MacDermid Responsive Br. at 9.) MacDermid contends that after broadly distinguishing the prior art on this basis, the applicant then pointed to specific absorption limitations present in only some of the claims. (Id. at 10.) MacDermid states that one of ordinary skill in the art would not view these statements as creating a percentage limitation for all claims. (Id.) As such, the statements cannot constitute a disavowal of scope. (Id.) MacDermid contends that DuPont looks to one statement without looking to the statement that precedes it, (Id. at 12.) It contends that there is no statement that would unambiguously disclaim the use of a support layer absorbing less than 80%.

MacDermid also highlights that in the prosecution history, a few pages before the disputed statement, when distinguishing the '835 Patent from Fan and Canty, the applicant specifically identified the claims that included a percentage limitation. (Tr. at 24.) MacDermid contends that the applicant made an identical argument when distinguishing from Fan and Kurtz. (Tr. at 25.) When distinguishing the '835 Patent from Canty and Fan, the claims that included a percentage limitation were specifically identified. (Id.) MacDermid contends that it follows when the same argument was made three pages later in the prosecution history, when distinguishing from Fan and Kurtz, one would know that the referenced limitations only applied to the specified claims, even though not specified in the second argument. (Tr. at 25.) It contends that DuPont has misrepresented MacDermid's statements and there is no clear disavowal of claim scope. (Id. at 26.)

DuPont contends that the disputed statement was directed toward all the claims, not only the claims containing percentage limitations. (Tr. at 71.) It rejects MacDermid's contention that the Court should look to the part of the prosecution history distinguishing the '835 Patent from Fan and Canty. (Id.) It states that that portion of the prosecution history is irrelevant. (Id.) DuPont states that the Kurtz patent provided for the absorption of most if not all of the exposure radiation. (Id. at 72.) To distinguish the '835 Patent from Kurtz, MacDermid argued that Kurtz does not specify that it is 80% or greater. (Id.) DuPont further notes that there were portions in the prosecution history that did refer to specific claims, but the statements made regarding the Kurtz and Fan patents did not, indicating that those statements did not refer to specific claims. (Id. at 75.)

The Court agrees with MacDermid's proposed construction that the support layer be construed as "a flexible transparent material upon which the photopolymer material is disposed." This construction comports with the plain language of the '835 Patent and the doctrine of claim differentiation. The Court further finds that the disputed statement in the prosecution history does not constitute a "clear disavowal of claim scope."

The Court looks to the words of the claims to define the scope of the patented invention. See Phillips, 415 F.3d at 1312; Golight, Inc. v. Wal-Mart Stores, Inc., 355 F.3d 1327, 1331 (Fed. Cir. 2004) (noting "[i]n construing claims, the analytical focus must begin and remain centered on the claims themselves" (citation omitted)). There is a "heavy presumption that a claim term carries its ordinary and customary meaning." Golight, 355 F.3d at 1332 (citation omitted). The Court agrees with MacDermid that DuPont's proposed construction reads an additional limitation into the term "support layer" that is not supported by the language of the claims.

The '835 Patent, in independent claims 1, 13, and 30, describes a support layer with no percentage limitation. ('835 Patent, col. 10, lines 43-45; col. 11, lines 65-67; col. 14, lines 14-19.) While there are some claims that include an absorption limit, the claims should be considered in the context of the other claims in the patent. Phillips, 415 F.3d at 1314. The doctrine of claim differentiation further provides that "[t]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." Id. at 1315. Dependent claims 16 and 17 of the '835 Patent include percentage limitations, while independent claim 13 does not contain such a limitation. As such, there is a presumption that the independent claim does not contain an absorption limitation.

The specification provides further support for MacDermid's proposed construction. It provides that the support layer "is preferably formed from a variety of flexible, transparent materials." ('835 Patent, col. 6, lines 20-22.) The specification contains no absorption limitation.
The Court also finds that there was no clear disavowal of claim scope in the prosecution history. "Where the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim" Golight, 355 F.3d at 1333 (citation omitted). Prior to making the statement currently in dispute, the applicant distinguished the claimed invention from Fan and Kurtz stating that those patents did not disclose that the support layer should absorb U.V. radiation, without indicating a percentage limitation. (Prosecution History at B 99.) The Court also notes that when distinguishing the claimed invention from Fan and Canty, the applicant made the same argument regarding U.V. absorption that it made to distinguish the claimed invention from Fan and Kurtz. (Id. at B 97.) When making the argument regarding Fan and Canty, the applicant specified that the absorption requirements it noted were limited to certain claims. (Id.) In making the same argument regarding the Fan and Kurtz patents, the applicant used the same language, but did not specify that the absorption requirements were limited to certain claims. (Id. at B 98.) Viewing the prosecution history as a whole and in view of the ambiguity created by the separate arguments, the Court finds that there was not a clear disavowal of claim scope. The statement does not rise to the level of an unequivocal disavowal.

B. Construction of Claim 1

In defendants' view the only term in claim 1 of the 374 patent that remains at issue is "support member" -- the object that is temporarily inserted in the meat that creates the axis about which the spiral is cut. 10 See 374 patent, claim 1, col. 10, lines 4-10. Defendants urge the following construction: (1) "support" means "to keep the uncut core of meat from failing in order to maintain the continuous spiral cut about the axis of the meat," and (2) "support member" is a "single structure" that provides this support and that "extends at least the length of the continuous spiral cut." 11 Defendants argue that this proposed construction is consistent with "spit," the term the parties recognize as Judge Werlein's construction of "support member" in the earlier case. 12 Plaintiff accepts Judge Werlein's construction of the claim terms -- including "support member" as "spit" -- but urges the court, if anything, to define "spit" as a "pointed rod" or "pointed rod for holding meat" and to construct "in the meat" as "into the meat" (as opposed to "through the meat"). 13 Plaintiff resists any construction of "support member" indicating a "specific type, style or size of spit." 14

--- Footnotes ---

10 Defendants' Opening Markman Brief, Docket Entry No. 42, p. 2.

11 Id. at 17-18.

12 Id. at 10-11. See also Plaintiff's Memorandum in Support of Its Combined Markman Brief and Motion for Partial Summary Judgment of Patent Infringement, Docket Entry No. 47, p. 9. It appears that "support member" was not directly at issue in the 374 patent case before Judge Werlein. He did not enter an explicit construction of "support member" in his memorandum and order construing other terms of the 374 patent claims. Judge Werlein did, however, use the word "spit" in apparent reference to "support member" throughout his construction of those other claim terms. See Defendants' Opening Markman Brief, Docket Entry No. 42, pp. 10-11; Memorandum and Order (Sept. 4, 2003), Logan Farms, Inc., et al. v. Honey Baked Ham, L.P., MI, et al., H-01-1611, Tab 3, Defendants' Appendix I, Docket Entry No. 46.

14 See id. at 13.

--- End Footnotes ---

The court begins by construing "support member" as "spit." This is consistent with both parties' arguments and their view of Judge Werlein's earlier construction of "support member." 15 Further, the parties appear to agree that spit is a "pointed rod." 16 Their dispute, and the court's focus, centers on whether the "support member" mentioned in claim 1 should be further construed with additional limitations based on its function.

- 4678 -
The claim language supports defendants' argument that the 374 patent requires a "support member" or "spit" that traverses the length of the spiral cut. The claim states that the uncut core of meat must be of sufficient cross-section to permit the meat to retain its shape when the support member is removed. 374 patent, claim 1, col. 10, lines 4-10. If the support member were shorter than the length of the spiral cut, the uncut core would have to be sufficient to provide for the meat's integrity during slicing operations as well as after, when the spit is removed. Otherwise, the meat would lose its shape as the slicer blade passed beyond the reach of the short spit, not just when the support member was removed. But claim 1 mentions nothing about maintaining the meat's shape prior to spit removal. Thus, the court concludes that the claim language contemplates a spit extending the length of the cut -- a spit that, while it remains inserted, supports the meat's shape regardless of the cross-section of the uncut core.

In responding to defendants' argument that "support member" contains a length limitation, plaintiff offers dictionary definitions suggesting "support" is synonymous with "hold." 17 His theory, as the court interprets it, is that "support member" need not be read to serve the function of providing structural support to the entire length of uncut core and therefore need not be limited to any minimum length. 18 The 374 patent's specification, however, appears to distinguish "support" and "hold." As plaintiff himself notes, the summary and written description refers to a "meat spit" inserted in the boneless product that is "designed to provide structural support for the meat during boneless cutting operations." 19 374 patent, col. 4, lines 5-7. See also 374 patent, col. 3, lines 63-65; col. 5, lines 61-64.

Moreover, it is the "chuck assembly," not the support member, that is "designed to hold and rotate the meat during cutting operations." 374 patent, col. 4, lines 1-2. The written description indicates that the meat is "held" by "the plurality of spikes" located on the faces of the upper and lower chucks. 374 patent, col. 9, lines 38-40.

The court is persuaded that the patent's repeated association of "spit" with "structural support" on the one hand, and "chuck assembly" and "spikes" with "hold" on the other, indicates a special role for "support member" beyond merely holding the meat. In other words, the difference in diction suggests "support member" cannot be just another spike, or even an elongated one, and indeed the written description discloses a spit that travels completely through the boneless meat product. 374 patent, col. 6, lines 1-3. Thus, the specification is entirely consistent with the court's initial reading of "support member" as a spit extending the length of the spiral cut that serves the particular function of helping the boneless meat maintain its shape.
The prosecution history confirms that "support member" should be construed along the lines of the court's interpretation of the claim language. During reexamination of his patent plaintiff "submitted videotaped evidence of the inoperability" of an abandoned prior patent application and "the patentably distinct product produced by [him] using the patentably distinct method." 20 The court has viewed this tape. 21 It depicts a series of attempts to spirally-slice boneless meat products. In three of those attempts no spit was used. Each time, regardless of the radius of uncut core -- which was as great as two inches -- the spit-less meat broke apart during slicing. 22 Plaintiff explained to the examiner that "the rotational force imparted on one end of the meat product . . . caused rotational stresses in the solid core of meat that caused the meat product to twist apart" despite the solid central core. 23 The core simply "lacked the necessary stability and physical integrity to prevent the [meat] from twisting apart." 24 As plaintiff stated, his "unique method" included a "spit through the center axis" that "provides the boneless meat product with sufficient structural stability during the slicing operation." 25 With the spit traversing the product, the meat did not twist apart in the final experiment on the videotape. Given this context it is clear that "support member" envisions a structure that helps the meat remain whole during slicing operations.

--- Footnotes ---

20 Response to Office Action Dated Sept. 10, 1992, at pp. 1-2, Tab 4, Defendants' Appendix I, Docket Entry No. 46.
21 Defendants have included a copy of the videotape at Tab 15, Defendants' Appendix I, Docket Entry No. 46.
23 Id.

Although it does not appear that plaintiff expressly stated in the prosecution history that the "support member" or spit must traverse the length of the spiral cut, the court is persuaded that no other conclusion is reasonable. Like the specification, plaintiff's videotaped demonstration of his "unique method" disclosed a spit extending through the boneless meat product. There is no hint that the benefit provided by the support member component -- which, according to any fair assessment of plaintiff's argument during reexamination, was an important part of his "patentably distinct method" 26 -- could be obtained with a shorter spit, much less with one that does not even traverse the length of the spiral cut. Moreover, plaintiff's representations before the examiner, like his claim language, suggest a support member or spit that is coextensive with the spiral cut. In his summary of the videotape segment depicting his method, plaintiff indicated that "after the boneless meat product has been sliced and the spit removed, the remaining solid central core of meat provides the spiral sliced boneless meat product with structural integrity. . . ." 27

--- Footnotes ---

26 Without it, plaintiff's method would be as inoperable as the three failed experiments depicted in the videotape. Plaintiff insists that he did not distinguish his invention from the prior art on the basis of any particular length spit. See Plaintiff's Memorandum in Support of Its Combined Markman Brief and Motion for Partial Summary Judgment of Patent Infringement, Docket Entry No. 47, pp. 13-14; Plaintiff's Response to Defendants' Cross-Motion for Summary Judgment of Non-Infringement, Docket Entry No. 55, pp. 8-9. However, the contrast between his method and the failed experiments indicates that a spit of at least some minimum length is a necessary part of the claimed invention.

--- End Footnotes ---
As the court's review of the intrinsic evidence indicates, the court concludes that defendants' proposed limitation of "support member" (incorporating their construction of "support") is correct. Accordingly, the court adopts the following construction of "support member": a spit (or pointed rod) that traverses the length of the spiral cut and helps the boneless meat product maintain its shape or integrity during slicing operations.

As noted above, plaintiff argues that "in the meat" should be read as "into the meat," not "through the meat." The court declines to adopt this construction. According to the court's reading of the 374 patent's claim 1, the spit may or may not extend completely through the meat. The claim language "in the meat" is consistent with either length spit.

--- Footnotes ---

28 See supra note 13 and accompanying text.

29 Plaintiff argues that the "principles of claim differentiation" compel the adoption "into the meat" for "in the meat," because other claims in the 374 patent require spits that are inserted "through the meat." Plaintiff's Memorandum in Support of Its Combined Markman Brief and Motion for Partial Summary Judgment of Patent Infringement, Docket Entry No. 47, p. 14. The court notes its construction of claim 1 does not require the spit to traverse the entire cut of meat but merely the length of the spiral cut.

--- End Footnotes ---

A. Claim Construction

We agree with the portion of the district court's claim construction that requires that the support member "help[] the boneless meat maintain its shape or integrity during slicing operations," however, the intrinsic record does not require the "support member" to "traverse the length of the spiral cut," so long as it is performing the function of helping "the boneless meat maintain its shape or integrity during slicing operations."

Logan argues that the "support member" should only be required to hold the meat. Logan cites numerous dictionary definitions in an attempt to bolster his argument. However, these dictionary definitions are inconsistent with the intrinsic record and therefore, are not probative. See Phillips v. AWH Corp., 415 F.3d 1303, 1322-23 (Fed. Cir. 2005) (en banc) (stating that courts may rely "on dictionary definitions when construing claim terms, so long as the dictionary definition does not contradict any definition found in or ascertained by a reading of the patent documents."). The '374 patent uses the term "hold" in reference to the chuck assembly, which includes a number of short spikes to help hold the meat. See, e.g., '374 patent, col.3, ll.53-57 ("The apparatus includes an electrically driven, rotating meat chuck assembly for holding the meat . . . during cutting operations"); id., col.4, ll.1-2 ("The chuck assembly is designed to hold and rotate the meat during cutting operations."). The specification indicates that the support member does more than "hold" the boneless meat-it provides support for the meat. See id., col.5, ll.61-64 ("The meat spit 400 is used in the slicing of boneless meats to provide support by inserting the stem member 404 into the meat during slicing operations.").

The prosecution history also supports this construction. During prosecution, Logan informed the Patent and Trademark Office that the support member "provides the boneless meat product with sufficient structural stability during the slicing operation" and that the spit "maintain[ed] meat integrity during the slicing operation." Moreover, during prosecution, Logan submitted videotaped experiments to establish that a particular reference was not enabled. These experiments are part of the intrinsic record, are properly considered in construing the claims, and further support this construction. Thus, we conclude that the support member "helps the boneless meat maintain its shape or integrity during slicing operations."

We do not agree, however, that the support member must "traverse the length of the spiral cut" as the district court required. Logan argues that Hormel's 1" and 2 3/8" prongs are "in the meat." Hormel argues that the support member must extend into the meat so as to traverse the length of the spiral cut. We conclude that the claim language "in the meat" does not require that the support member extend through the entire meat product nor does it require the support member traverse the entire spiral cut portion. Nothing in the specification or prosecution history requires this narrow construction.
Claim 1 requires only that the support member be "in the meat." '374 patent, col.10, ll.6-7. Other claims require that the "support member [be] inserted through the annular core [of meat] prior to slicing . . . ." Id., at col.10, ll.13-14 (claim 2) (emphasis added); see also id., at col.10, ll.27-28 (claim 4), col.11, ll.7-8 (claim 10). Hence, while claims 2, 4, and 10 require the support member be inserted through the meat, claim 1 in contrast only requires that the support member be in the meat. Because the patentee used different terminology in different claims, there is a presumption that there is a difference in the scope of the claims. See Forest Labs., Inc. v. Abbott Labs., 239 F.3d 1305, 1310 (Fed. Cir. 2001) (citing Tandon Corp. v. U.S. International Trade Com., 831 F.2d 1017, 1023 (Fed. Cir. 1987)). We conclude that "in the meat" must be read in conjunction with "support member" and that therefore the claim requires that the support member be in the meat far enough to "support" the meat during slicing (i.e., to maintain its shape or integrity during slicing).

While the specification discloses only a single embodiment, the intrinsic record does not limit the scope of the term "support member" to the only disclosed embodiment. See Phillips, 415 F.3d at 1323 ("[W]e have expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment."). Thus, it is improper to read the sole embodiment from the specification into claim 1 and require that the support member extend through the meat. We also do not believe that the support member must extend the length of the spiral cut because while the claim requires the support member to define an "axis" of the meat, there is no reason why a support member that does not traverse the length of the spiral cut cannot define such an axis.

We conclude that the support member must extend into the meat to a sufficient length to support the meat during cutting (to help the meat maintain its shape or integrity during slicing), but not necessarily extend through the meat or traverse the entire length of the spiral cut.

4 The '739 utility patent covers, inter alia, a specifically defined "eyeglass display" which, according to independent claim 1, comprises:

a support member;

one or more display members having a plurality of openings, wherein each of said plurality of openings is adapted to receive an eyeglass case and is configured to permit a consumer to view at least a portion of the eyeglasses enclosed therein, wherein at least one eyeglass case is received by one of said plurality of openings and is displayed in a substantially vertical manner, said eyeglass case comprising . . . .

(739 patent, col. 9, ll.11-19) One of the limitations in dispute is "support member," a phrase not used in the specification or the figures. Rather, the specification and the corresponding figures refer to "support structure' 120," which is described variously as "provid[ing] a frame for securing other components of display 100" 5 ("739 patent, col. 6, ll.65-67), "provid[ing] a central frame mechanism to which display members 130a-h are coupled" (739 patent, col. 8, ll.12-14), and having "a skeleton frame configuration to provide support to five display members on each of four sides of the display" (739 patent, col. 8, ll.27-29). Given the description of a "support structure" in the specification, which is consistent with the ordinary meaning of the word "support," 6 the court concludes, consistent with the tenets of claim construction set forth by the United States Court of Appeals for the Federal Circuit in Phillips v. AWH Corp., 415 F.3d 1303 (Fed. Cir. 2005), that the limitation "support member" shall be construed (for purposes of these preliminary proceedings) as "a structure for securing other components of the display." Comparing the elements of the accused device to the limitation as construed, it is clear that the accused product does not have a support member as described in claim 1. 7 Therefore, plaintiff has failed to establish a likelihood of success on the merits in this regard.

4 Plaintiff has moved to amend the complaint to add U.S. Patent No. 7,188,739 ("the '739 patent"), which motion (D.I. 32) is granted, as leave to amend "shall be freely given when justice so requires," Fed. R. Civ. P. 15(a), especially when the
motion is filed early in the case, as this motion was.

5 The specification goes on to state that "[d]isplay member 130 is coupled to support structure 120 and/or base 110." ('739 patent, col. 6, l.67 - col. 7, l.1) Plaintiff argues that the above language demonstrates that a "support" member need not be functional. The court disagrees.

6 To "hold up or in position; to serve as a foundation or prop for; bear the weight or stress of; keep from sinking or falling." Webster's Third New International Dictionary (Merriam-Webster, Inc. 1993) at 2297.

7 The specification describes all the embodiments of the claimed display as being comprised of at least a base, a support structure, a display member, and a display surface. It is clear that the back panel of the accused product provides no support to any other component, not even an attached logo, as depicted in figure 5 (display surface 150) of the '739 patent.8 The court declines to address any other of the disputed limitations in this proceeding.

Construction of Claim 7

As noted, at issue in this case is the meaning of the term "support member" as used in claim 7. The court begins, as it must, with the language of the claim (Vitronics, 90 F.3d at 1582):

7. A rotatable handgrip actuating system for releasing or pulling a tensioned cable, the system comprising:

   a support member having a generally cylindrical outer surface;

   a grip disposed over said generally cylindrical outer surface of said support member and rotatable relative thereto in a first direction and in a second direction opposite said first direction, a generally cylindrical inner surface of said grip facing said outer surface of said support member, one of said inner surface and said outer surface having a plurality of detent positions formed therein; and

   a spring metal detent spring disposed between said grip and said support member and engageable with one of said detent positions, said detent spring providing a first resistance against being forced out of said one detent position when said grip is rotated with respect to said support member in said first direction, said detent spring providing a second resistance against being forced out of said one detent position when said grip is rotated relative to said support member in said second direction, said second resistance being greater than said first resistance, the difference between the first and second resistance due at least in part to the shape of the detent spring.

000 patent, column 8, lines 25-45.

SRAM argues that "support member" must be given its ordinary meaning. Quoting Random House Webster's Collegiate Dictionary, SRAM argues that "support" means to "bear or hold up (a load, mass, structure, etc.)" or to "sustain or withstand (weight, pressure, strain, etc.)," while member refers to "a constituent part of any structural or composite whole." Applying the "plain meanings" to the claim, SRAM argues that the "support member" is "a portion of the shifter that cooperates with the other components of the shifter to bear a portion of the load of the handgrip and the spring when the shifter is in operation and when the spring engages the detent position or notches." Thus, SRAM argues that nothing in the plain language requires the support member to be stationary and nothing requires the support member to "retain" the spring. Indeed, SRAM argues that the claim suggests the opposite by providing that "a spring metal detent spring [is] disposed between said grip and said support member."

Read literally, the language of claim 7 contains no limitation that the "support member" is either stationary or spring retaining. The court does not read the claims in a vacuum, however, but rather "in view of the specifications of which they are a part." Markman v. Westview Instruments, 52 F.3d 967, 979-80 (Fed. Cir. 1995). As noted above, claim 7 (prosecution
claim 36) was initially rejected by the examiner as "vague and indefinite" because "antecedent basis is lacking in the specification, in the form of language followed by a reference character for 'support member.'" As explained by SRAM's counsel at oral argument, the reason for the rejection was that the term support member had never been used in the specification and had not been identified on any of the drawings. To overcome this rejection, SRAM was required to and did amend the specifications both to introduce the term "support member" and to give it a drawing character reference. It accomplished this task by amending the description of the first preferred embodiment in the specification at page 10, line 16 of the original application, adding the phrase "or support" after the word retaining in the phrase "spring retaining member" and, the numerical designation "40" after the word member. The examiner ultimately accepted this amendment, leaving the final patent specification to read (column 5, lines 1-5):

The stationary portion of the rotatable grip actuating system includes the mandrel 20 (FIG. 4) and a spring retaining of support member 40 having an outwardly facing generally cylindrical surface in which is formed a spring retaining elongated notch 42. [All character references are to FIG. 4 which is attached to this opinion as Exhibit A]

It is this amendment that gives rise to AD-II's argument that the support member must be stationary, because the term was first identified in the portion of the specification describing the "stationary portion of the rotatable grip actuating system." To support this argument, AD-II cites to two separate sections of the amendment. First, in summarizing the response submitted to overcome the antecedent basis rejection, the remarks accompanying the amendment state "to overcome this rejection with respect to 'support member,' Applicants have amended the detailed description at p.10 line 16, to make clear that the spring retaining member 40 (itself an extension of mandrel 20) is the support member recited in the claims." Next, AD-II points to the last substantive paragraph of the remarks, which states:

This specification has also been amended to correct an incorrect description of the operation of the device. With reference to FIGS. 5 and 6 and FIGS. 3 and 4, it is clear that mandrel 20 and spring-retaining or support member 40 are affixed to handlebar 12 of the bicycle. Handgrip 18, to which is affixed wall 56 with detents 50, 52 and 54, is rotated by the rider around the mandrel 20. Hence it is wall 56 and handgrip 18 which are rotated, and any passage describing the rotation of mandrel 20 or spring-retaining member 40 is incorrect. Amendments to the Detailed Description beginning at line 9 at page 11 and continuing to line 15 at page 12 correct the description of the operation of the device . . .

AD-II argues that together these remarks demonstrate that the term "support member" as used throughout the claims must always retain the spring and must always be stationary, with the wall 56 and handgrip 18 being the only elements that rotate.

At first glance, this argument is appealing in its simplicity. Closer examination reveals certain flaws with such a simplistic view. First, as pointed out by the court at oral argument, the third preferred embodiment of the final patent describes a mode of the invention in which the "spring retaining member is rotated in either direction with respect to the wall 56 . . ." (000 patent, column 6, lines 45-47). AD-II suggests that in light of the amendment, the retention of this language in the third preferred embodiment referring to rotation of the spring retaining member is a mistake, and the court should either ignore the third preferred embodiment or construe the patent as not reading upon it. An interpretation that defines the invention in such a manner that excludes a preferred embodiment is rarely, if ever, correct, however, and requires highly persuasive evidentiary support not present in the instant case. See Vitronics, 90 F.3d at 1583; Modine Mfg. Co. v. United States Int'l Trade Comm'n., 75 F.3d 1545, 1550 (Fed. Cir. 1996).

Moreover, it is clear that the attorney remarks in the amendment referred to above are restricted to the description of the first two preferred embodiments. When SRAM amended the specifications to provide the antecedent basis for "support member" it did so in its description of the first preferred embodiment. But identifying the support member as the same element (40) as the spring retaining member, simply means that the support member is the same thing as the spring retaining member. In the first two preferred embodiments, the spring retaining member (40) must be stationary. In the third preferred embodiment, however, the spring retaining member rotates. This conclusion is buttressed by the wording of the remark that tends, at first glance, to indicate that the support member must always be stationary. That paragraph (quoted above) specifically refers to FIGS. 5 and 6 and FIGS. 3 and 4, which are the drawings of the first two preferred embodiments. The paragraph makes no reference to FIGS. 8 and 9, which detail the third preferred embodiment. Therefore, the court rejects AD-II's argument that SRAM disclaimed patent coverage of shifters in which the spring retaining or support member rotates.

The court agrees with AD-II, however, that the support member must retain the spring. To overcome the lack of an antecedent basis rejection, SRAM identified the term support member as element 40 -- the spring retaining member. In its
briefs, SRAM again argues that the amendment refers to the first and second preferred embodiments only and, therefore, the support member must be the spring retaining member in the first two preferred embodiments only. At oral argument, however, SRAM's counsel admitted numerous times that the support member is element 40 throughout the specifications.

THE COURT: I may be missing something here. In that you're saying -- as I'm reading the third preferred embodiment, you're saying that the spring retaining member -- remember, you don't use support member there; you only use spring retaining member.

MR. JANOSKI: "No. 40, it's no. 40, whether you call it-identify it as spring retaining member or support member, it's item 40. Its part no. 40." (Transcript May 30, 2001, p.26 11. 12-20)

MR. JANOSKI "…and after that, he could have used, if he would have said like here, spring retaining or support member 40, well now 40 can be used identified as either spring retaining or support member throughout the detailed description of the preferred embodiment." (p. 361.23 - p.37 1.2)

Therefore, the support member is element 40 in all embodiments, and it is the spring retaining member in all embodiments. In preferred embodiment one and two the spring retaining or support member must be stationary, and in preferred embodiment three it may rotate.

Having determined that the term "support member" is simply another phrase for the term spring retaining member, construction of the claim is simple. One need only substitute "spring retaining" for "support" throughout claim 7 to achieve clarity.

a [spring retaining] member having a generally cylindrical outer surface;

a grip disposed over said generally cylindrical outer surface of the said [spring retaining] member and rotatable relative thereto in a first direction and in a second direction opposite the said first direction, a generally cylindrical inner surface of said grip facing said outer surface of said [spring retaining member] one of said inner surface and said outer surface having a plurality of detent positions formed therein.

The term support member is construed to mean spring retaining member. There is little disagreement between the parties as to the term "a generally cylindrical inner surface of said grip facing said outer surface of said support member, one of said inner surface and said outer surface having a plurality of detent positions formed therein." (000 patent, column 8, lines 31-35). The terms "inner," "outer," and "facing" all refer to the orientation of the support member and handgrip. The inner surface of the grip (wall 56) must face the outer surface of the support member such as element 42 in Exhibit A. The detent position of notches must be on either the inner surface of the grip (wall 56) or on the outer surface of the support member.
enables the valve to be removably attached to a fluid dispenser or container.

Col. 4:26-33. This description reveals that there is nothing inherent in "the manner" the support member supports the valve that relates to its ability to be "removably attached to a fluid dispenser." In fact, this excerpt demonstrates that the support member may allow the valve to be removably attached to a fluid dispenser either by having a part that is a "Luer-Lock type connector" or by itself being in the form of an adaptor that provides that ability. Braun's limitation is consequently refuted by the intrinsic evidence.

Accordingly, the term "support member" shall be construed in the manner proposed by ICU.

2. The '139 patent

Claim 3 of the '139 patent recites:

A lighting fixture for mounting fluorescent lamps, comprising:

a) a support member having an upper surface;

b) a plurality of lamp supports mounted on the upper surface of said support member for engaging and supporting said fluorescent lamps adjacent their non-socket ends;

c) said plurality of lamp supports being equally spaced apart in a straight line;

d) a plurality of sockets corresponding to said plurality of lamp supports for receiving said fluorescent lamps mounted on the upper surface of said support member and being equally spaced apart in a straight line each of said plurality of sockets being adjacent the socket end of one of said fluorescent lamps; and

e) the spacing between each of said plurality of sockets and each of said corresponding lamp supports being less than the length of one of said fluorescent lamps, so that the non-socket end of one fluorescent plurality of lamps mounted on one of said lamp supports overlaps the socket end of an adjacent fluorescent lamp so as to provide shadowless and continuous linear lighting.

'139 patent, col. 2, line 55, through col. 4, line 3 (emphasis added). Birchwood argues that the prosecution history of the '139 patent requires that the "lamp supports" of claim 3 be limited to ramps. The district court disagreed with Birchwood, and so do we.

The original application that matured into the '139 patent included three independent claims: claim 1, which recited ramps as the lamp supports; claim 3, which recited a plurality of lamp supports mounted adjacent to the non-socket ends of the lamps; and claim 5, which recited a plurality of lamp supports mounted adjacent to the socket ends of the lamps. The examiner found that the application contained claims directed to patentably distinct species of the claimed invention and contained no generic claim. Accordingly, pursuant to 35 U.S.C. § 121, the examiner required the applicant to elect "a single disclosed species for prosecution on the merits to which the claims shall be restricted if no generic claim is finally held to be allowable." In response, the applicant cancelled claims 5 and 6, which recited lamp supports adjacent to the socket end of the lamps.

In its initial claim construction order, the district court construed "lamp supports" to be limited to ramps, because ramps were the only form of support disclosed in the drawings that related to elected claims 1 through 3. On Lighting World's motion for reconsideration, however, the court reversed itself, holding that the examiner's allowance of claim 4, which specifically claimed posts as lamp supports and was dependent on claim 3, necessarily indicated that the examiner had not required the application to be limited to lamp supports in the form of ramps.
We agree with the district court that the election did not require that the "lamp support" limitation be confined to ramps. The election had nothing to do with the type of lamp support claimed; rather, it had to do with whether the support was provided to the socket end of the support members or to the non-socket end. The ramp supports, like the posts recited in claim 4 and the lamp supports recited in claim 3, all provide support for the non-socket end of the lamps. Since the claims that remained upon issuance were all claims in which support was provided at the non-socket ends, the patent as issued was consistent with the applicant's election. The court therefore properly declined to limit the lamp supports of claim 3 to ramps.

Although the district court rejected Birchwood's argument that claim 3 of the '139 patent is limited to ramps, the court agreed with Birchwood that claim 3 is limited in another respect that defeated Lighting World's claim of literal infringement. The court ruled that the claimed lamp supports were limited to those providing support from below, i.e., those that would work only if the lamps were oriented toward the ceiling and that would support the lamp against falling down into the socket end of an adjacent lamp. The court explained its ruling by stating that "reading the patent as a whole, it is clear that the lamp support contemplated by claim 3 is intended to support the lamp from below, in order to prevent the angled lamp from falling on the socket in front of it."

We disagree with that aspect of the court's claim construction. While it is clear that the claimed lamp supports provide support from below, we do not agree with Birchwood or the district court that claim 3 is limited to lamp supports that provide support only from below and that the claim does not include lamp supports that provide support when the lamp is in an orientation other than directly above the support.

Birchwood argues that the terms "engaging and supporting," as used in claim 3 of the '139 patent must be interpreted to mean engaging and supporting only from below. Birchwood contends that the figures of the '139 patent, in particular, depict various lamp supports, all of which consist of structures—such as ramps, posts, or brackets—on which the lamps rest. According to Birchwood, "it is the force of gravity and the position of the lamp relative to the 'lamp supports' alone that causes the lamp to engage with and be supported by the 'lamp supports.'" Birchwood argues that the lamp supports depicted in the figures and described in the specification are all below the lamps and do not provide support for the lamps when the lamps are below the supports, such as when the supports are attached to the ceiling. By contrast, the Birchwood lamp support features what the district court referred to as a "clip around the fluorescent lamp in order to provide support regardless of the orientation of the lighting fixture." Birchwood thus distinguishes its lamp supports from those claimed in the '139 patent by arguing that its lamp supports engage the lamp on all sides "and could engage and support the lamp regardless of the orientation of the lamp," while the Lighting World lamp supports engage and support the lamps purely as a result of gravity and the lamps' position relative to the lamp supports.

There are several problems with Birchwood's analysis. First, the reference to "lamp supports" in claim 3 of the '139 patent is not by its terms limited to supports that engage and support the lamps from below, and there is no language in the written description that limits the term "supporting and engaging" to support and engagement from below. Second, although several of the figures of the '139 patent show lamp supports that provide support from below the lamps, the scope of the claims is not limited to particular embodiments depicted in the figures or described in the written description. The ordinary meaning of the terms "supporting and engaging" includes more than support or engagement from below, and the fact that the patentee has not included figures depicting support and engagement from other orientations is not sufficient to limit the claim language to the particular orientation depicted in the figures. Third, several of the figures of the '139 patent include a device that appears to clip around the lamps and thus provides support and engagement for the lamps that would be effective in other lamp orientations. Birchwood argues that the clip is unclaimed and thus is dedicated to the public, but that argument misses the relevance of the clip. Lighting World does not point to the clip as a claimed feature, but instead refers to the clip to show that its use of the terms "supporting and engaging" was not meant to be limited to support and engagement from below. Finally, Birchwood's argument that its support mechanism provides support in many orientations rather than merely from below does not avoid the patent's claim to a mechanism for "supporting and engaging" the lamps, but at most simply reflects an additional feature not present in the device claimed in the patent. Making improvements on a patented invention by adding features to a claimed device beyond those recited in the patent does not avoid infringement. Hoyt v. Horne, 145 U.S. 302, 309, 36 L. Ed. 713, 12 S. Ct. 922, 1892 Dec. Comm'r Pat. 435 (1892); A.B. Dick Co. v. Burroughs Corp., 713 F.2d 700, 703 (Fed. Cir. 1983).

Contrary to Birchwood's argument, the use of the term "upper surface" in the '139 patent does not indicate that the claimed lamp supports include only those that provide support solely from below. Birchwood's argument is based on the limitation that requires a plurality of lamp supports to be mounted "on the upper surface of said support members." Nothing in the
patent suggests that the "upper surface" of the support member ceases to be the "upper surface" if the fixture is turned upside down or placed in some other orientation. Nor is there any suggestion in the patent that the fixture must always be oriented so that its "upper surface" faces upward.

In sum, we construe "support member" to refer to a member that is mounted to the same surface as the lamp and that supports the lamp at its non-socket end. Because summary judgment of no literal infringement of the '139 patent necessarily rested on the district court's erroneous claim construction, the district court's ruling on that issue must be vacated.

(b) "Support plate" A support plate must be a physical structure. A "plate" suggests a more or less flat surface. A "support" plate is a plate that serves as a "foundation, prop, brace or stay." See Webster's College Dictionary 1343 (Random House 1992) (defining the noun "support"). It must be sturdy and large enough to bear up, or prevent from falling free, the object or objects it is designed to "support."

C. "support structure" (claims 6, 10, and 20)
PolyVision's proposed construction
No construction required. Alt.: A structure serving as a support or foundation.
Smart's proposed construction
Structure used to support the claimed membrane and the claimed conductive surface underlying the membrane.

PolyVision contends that this term is basic and needs no construction. Smart, on the other hand, contends that the term is unclear because its meaning depends upon the context in which it is used. Smart notes, for example, that the support structure "includes flexible walls which are pretensioned to deflect and maintain tension on the membrane," (Col. 2, ll. 11-13), "may include a base and a support substrate mounted on the inside of the base," (Col. 2, ll. 30-32), and "may include a base and the spacer means may be mounted on the outside of the base." (Col 2, ll. 34-36.) In addition, Smart notes, claims 1-14 of the patent state that the "support structure" includes "spacer means," but claims 15-25 contain no such requirement.

While the term "support structure" seems relatively clear, Smart's construction provides further clarity by emphasizing that it is the part of the invention that supports the membrane and the underlying conductive surface, regardless of whether the embodiment includes a support substrate or spacer means. The Court will thus adopt this construction, although it will omit Smart's references to the membrane and the conductive surface as "claimed" because it is clear that those elements are set forth in the claims, and adding the word "claimed" would not serve any purpose.

The Court construes "support surface" as "surface that supports the base." As the intrinsic evidence does not provide a special meaning for "support surface," its plain and ordinary meaning applies. Enercon GmbH v. Int'l Trade Comm'n, 151 F.3d 1376, 1384 (Fed. Cir. 1998).

MASS proposes the term means "work surface that supports the base." MASS relies on a statement made during
prosecution, “this [base] is used to support the arm assembly above a work surface.” MASS’s Opening Brief, Ex. C. MASS contends that it defined “support surface” as a “work surface.” However, neither the claim language nor specification mentions a “work surface.” The specification states that in one embodiment the base stands on a horizontal surface, but it does not refer to, nor require it to be, a “work surface.” ‘978 patent, Col. 3:21–22. Furthermore, MASS’s proposed construction is ambiguous and would be unhelpful to the fact-finder, as “work surface” is not defined.

Defendants propose “the support surface is an area for supporting a display system.” The specification describes the support surface as the horizontal surface on which the base stands. See id. Thus, it is more accurate to state that the support surface supports the base. Accordingly, one of ordinary skill in the art would understand that “support surface” means a “surface that supports the base.”

II. Claim Interpretation

The dispute between the parties lies in the construction of Claims 4 and 5 of the '064 patent. Claim 4 reads as follows:

A nestably stackable assembly for use in a bedding foundation comprising a rectangular border wire having two parallel sides and two parallel ends, transversely-spaced, parallel, and longitudinally-extending support wires parallel to said border wire sides and having ends connected to said border wire ends, said support wires being formed so as to be generally corrugated along their lengths, said corrugatedly formed support wires having peaks and valleys, said peaks being flattened at their tops, said flattened peaks being generally coplanar with a plane defined by said border wire, said valleys being vertically displaced beneath and intermediate of said flattened peaks, and longitudinally-spaced, parallel, and transversely-extending upper connector wires parallel to said border wire ends and having ends connected to said border wire sides, said upper connector wires being connected intermediate of their ends along their lengths to said flattened peaks of said support wires.

The language of Claim 5 is nearly identical to that of Claim 4, with the exception of additional language in Claim 5 that is not in dispute. Neither party suggests that the term "support wires" has a different meaning in Claim 4 versus in Claim 5, and our construction of the term will apply to both claims. See Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir. 1995) (disputed terms must be construed within the context of the patent claim as a whole, and must be interpreted consistently throughout the claims of a patent).

A. "Support Wires"

The parties ask the Court to construe the term "support wires" found in the disputed claims. L&P argues that "support wires" can be made from a single, continuous piece of wire, and can also be fashioned from "more than one wire welded together." (R. 49, Pl.'s Post-Markman Hr'g Br. at 1.) Under L&P's suggested definition, any number of wires, once welded together in some manner, becomes a single "wire," which in turn can qualify as a "support wire," as used in the '064 patent. Hickory, on the other hand, asserts that the term "support wires" is limited to formation from a continuous strand of wire. Hickory acknowledges that a continuous strand of wire can be formed from shorter segments of wire, if they are butt welded, end to end. (R. 50, Def.'s Post-Markman Hr's Br. at 2.) In contrast, according to Hickory, pieces of wire welded together, not at their ends, but at a different location such that the finished welded combination of wires has more than two ends, cannot qualify as a continuous strand of wire.

References in this opinion to L&P's proposed construction of support wires ("more than one wire welded together") do not include wires butt welded end to end because both parties agree that such a construction could be used to make "support wires." Instead, where we discuss L&P's proffered definition, we will be focusing on the viability of a construction that encompasses pieces of wire joined somewhere other than at their ends, as that is the crux of the disagreement between the parties' proposed claim constructions. We begin our claim construction by looking at the patent.

1. Claim Language

The claim language, on its face, does not specify whether the term "support wires" would include, as L&P urges, "more than
one wire welded together." (R. 49, Pl.’s Post-Markman Hr’g Br. at 1.) However, the claim language does use "support wires" in the plural. The plain meaning of the claim language thus requires that there be more than one discrete "support wire." See Superior Fireplace Co. v. Majestic Prods. Co., 92 F. Supp. 2d 1001, 1010 (C.D. Cal. 2000) (finding that term "rear walls" requires at least two rear walls); Thomson Consumer Elecs., Inc. v. Innovatron, S.A., 43 F. Supp. 2d 26, 32 (D.D.C. 1999) (construing term "corresponding contact surfaces" to be "more than one contact surface, but not necessarily all contact surfaces"). Use of the plural "support wires" in the claims casts doubt on L&P's proposed construction, i.e. that any number of wires welded together creates a single wire. Under L&P's definition, all the welded wires contained in the entire '064 product would be considered only a single wire. In fact, although we do not rely on it, we note that L&P's own expert witness specifically stated that all the wires in the '064 invention constituted only a single wire. (Hr'g Tr. at 126, lines 6-13, Dr. Creighton.) Such a construction would run counter to the claim language which requires more than one support wire. In addition, although, as explained below, we will not construe other terms in the patent, we question how such a support wire (i.e. made up of every wire in the structure) could comply with the limitations of the support wires. For example, how could a single wire be "transversely spaced"? "parallel"?

2. Specification

We next look to the specification, which describes two preferred embodiments of the '064 invention. The '064 patent makes clear that other embodiments are possible, and the claims should not be limited to the preferred embodiments. In construing claims, we may not read a limitation into a claim from the written description, i.e. the specification. Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998). On the other hand, use of the term "preferred" does not of itself broaden the claims beyond their support in the specification." Wang Lab., Inc. v. America Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999). In this case, the written description and the drawings lead us to conclude that "support wires" are made from continuous strands of wire, as Hickory asserts.

First, the written description contains references to a number of other wires, e.g. a border wire and connector wires, and each type of wire is individually identified as a separate wire. Importantly, even where the specification teaches that a wire is welded to another wire, each of the original wires maintains its individual name and separate identity. For example, the specification teaches that the "support wires" are welded to the "upper connector wires," yet both types of wire are individually identified; the upper connector wires do not become part of the "support wires" simply because they are welded to them. ('064 Patent, col. 3, lines 3-5.)

Furthermore, if we were to adopt L&P's proposed construction that a wire can be made up of any number of pieces welded together in some fashion, the '064 invention would be nearly impossible to construct. The Patent Statute is clear that the specification must contain a written description of the invention "in such full, clear, concise, and exact terms as to enable any person skilled in the art . . . to make and use the same." 35 U.S.C. § 112, P 1. If a "wire" could consist of any number of wires welded in any manner, a person skilled in the art would have an infinite number of choices to make in attempting to construct the '064 invention. 2

2 We note that L&P's construction of the term "support wires" would seemingly encompass any grouping of welded wires, so long as one could trace a path in the tangle of wires that could comply with the rest of the limitations. We do not believe that the patent laws were intended to afford such far-reaching protection.

The specification also clearly refers to "support wire ends," which must be attached to the border wire, and describes that the "ends 14 . . . are crimped around the ends 12, 12 of the border wire 10." ('064 Patent, col. 2, lines 57-59.) 3 The only support wire ends described in the specification are attached to the border wire. Common sense dictates that the support wire ends are attached to opposite sides of the border wire. The specification does not mention any additional ends that are not attached to the border wire, which would give credence to L&P's proffered construction that a "support wire" can be composed of multiple wires welded together and, consequently, have any number of ends.
Finally, the drawings in the specification strongly suggest that a support wire must be a continuous wire. The support wires, referred to with the numeral 13, are shown in the drawings as continuous wires stretching from one side of the border wire to the opposite side.

Although we recognize that we cannot read limitations into the claims from the specification or drawings, we also are cognizant that the specification is "highly relevant" and serves as the "single best guide to the meaning of a disputed term." Vitronics, 90 F.3d at 1582. In this case, the specification and drawings provide no indication that the inventor intended the term "support wires" to encompass any number of wires, so long as they are welded together in some fashion as L&P suggests. See Quality Semiconductor, Inc. v. Pericom Semiconductor, Inc., 1998 U.S. Dist. LEXIS 22633, No. C-95-01785 MHP, 1998 WL 118186, at *3 n.1 (N.D. Cal. Mar. 2, 1998) ("The specifications and accompanying diagrams of the '062 patent provide no indication that the inventor intended the term 'a transistor' to encompass several transistors connected in parallel [as the plaintiff asserts].") The specification of the '064 patent supports Hickory's proposed definition of "support wires" as being continuous strands or multiple wires butt welded, end to end.

3. Prosecution History

The '064 patent application was granted without any amendments. The examiner, in his Statement of Reasons for Allowance, cited three prior art patents and explained that there are three main differences between the '064 product and prior art: (1) the modular springs of the prior art do not extend from one boxspring end to the other as does the claimed product, instead they extend from side to side of the boxspring; (2) the modular springs in the prior art "are not connected to the border wire at their ends as claimed, instead the modular spring ends are connected to the supporting base frame of the boxspring"; and (3) "the transverse grid wires of the prior art are not connected to the upper portions of the modular springs, instead they only contact the springs." (R. 16, Pl.'s Claim Construction Br., Ex. 3, Examiner's Statement of Reasons for Allowance of '064 Patent.) None of these reasons explicitly addresses whether "support wires" can be made from two or more wires welded together.

L&P argues that the prior art cited by the examiner supports its proffered construction of "support wires." First, L&P cites the Valoff patent (No. 4,069,525) and contends that it teaches that a support wire can be made by welding multiple wires together. The reference in Valoff, however, is to a border wire and not to a support wire. Furthermore, the Valoff patent specifically teaches that the wires making up the border wire are "welded at their ends to form in effect a continuous rectangle." (Valoff Patent, col. 3, lines 55-56.) As noted above, Hickory does not dispute that welding pieces of wire, end to end (i.e. butt-welding), forms a continuous wire. Hickory does dispute, however, that wires joined not at their ends but elsewhere constitute a support wire. Contrary to L&P's assertion, Valoff does not support such a construction.

L&P also argues that the Schulz patent (No. 4,377,279) teaches that support wires can be made from multiple wires welded together. The Schulz patent, however, refers to "support members" not to "support wires." Although L&P submits extrinsic evidence in an attempt to demonstrate that support wires have the same meaning as support members, 4 review of such extrinsic evidence is not necessary to determine the claim construction in this case, and we will not rely on it.

4 L&P's extrinsic evidence includes the reference in Hickory's allegedly infringing patent (No. 5,967,499) to the support wires in the '064 patent as "support modules." In addition, L&P relies on Dr. Stoll's testimony that "support wires" are sometimes referred to as support legs, members, or modules. (See R. 49, Pl.'s Post-Markman Hr'g Br. at 8 n.12; Hr'g Tr. at 187.)

Hickory also asks us to consider extrinsic evidence to help understand the prosecution history. Hickory argues that, according to its expert, the examiner looked only at prior art with support members that were planar specifically because he
considered the application for the '064 patent to be concerned only with two-dimensional support wires. The examiner, however, never stated that he was considering the prior art patents because they contained planar (and not three-dimensional) support members and certainly never stated that the support wires must be two-dimensional. Here again, we will not rely on Hickory's extrinsic evidence.

The meaning of the term "support wires," as used in the '064 patent, is unambiguous in light of the intrinsic evidence. Therefore, it is unnecessary and, in fact, would be improper for us to rely on extrinsic evidence for claim interpretation. Vitronics, 90 F.3d at 1583. See also Real v. Bunn-O-Matic Corp., 100 F. Supp. 2d 844, 847 (N.D. Ill. 2000).

B. L&P's Extrinsic Evidence

L&P spent the bulk of its time at the Markman hearing and in its post-hearing brief discussing extrinsic evidence. Because the intrinsic evidence in this case demonstrates that the term "support wires" as used in the '064 patent is unambiguous, we will not rely on the extrinsic evidence but will only briefly note that L&P submitted extrinsic evidence in the form of expert witness testimony and physical evidence (e.g. a series of "wires" formed from one or more individual wires). We find, in any event, that this subjective extrinsic evidence is not entitled to any weight because it is not supported by any objective evidence. L&P provides no documentary evidence that wires are made from multiple wires welded together. See Quality Semiconductor, 1998 U.S. Dist. LEXIS 22633, 1998 WL 118186, at *4 ("something more than simple assertions provided by the inventor and a single expert are required to create or establish the presence of an ambiguity").

III. Additional Elements in the Disputed Claims

Both parties' pre-Markman hearing briefs focused only on the meaning of "support wires." 5 As a result, in our April 5, 2000 Order, we specifically stated that "we expect the parties will, in accord with their written representations, limit their presentations to the term 'support wires.'" (April 5, 2000 Order at 1.) We are disappointed that Hickory has shifted gears and, in spite of their earlier representations, now urges us to construe a number of additional terms found in Claims 4 and 5.

5 To be precise, L&P's first claim construction brief attempted to define the term "generally corrugated," but Hickory, in its response, asserted that "the primary issue is the meaning of 'support wires.'" (R. 20, Def.'s Claim Construction Br. at 1), and therefore focused its brief solely on its proffered claim construction of that one term.

We decline to construe any additional terms at this point for a number of reasons. First, L&P asserts, and we agree, that allowing claim construction of additional terms would prejudice L&P, which prepared for the Markman hearing based on Hickory's prior representations and our Order focusing claim construction only on the term "support wires." Hickory had ample opportunity to alert both the Court and L&P of their changed position that they sought construction of additional terms but did not do so.

In addition, Hickory earlier admitted that at least some of the elements, which Hickory now argues are in dispute, are contained in their product. These admissions are binding for purposes of claim construction. See Evans Medical Ltd. v. American Cyanamid Co., 1999 U.S. App. LEXIS 18436, Nos. 98-1446, 98-1459, 1999 WL 594310, at *6 (Fed. Cir. Aug. 9, 1999) (construing a claim, in part, based on the plaintiff's response to an interrogatory, which it considered a "binding admission"). Finally, in view of our construction of the term "support wires" in Hickory's favor, there is no need to construe any additional terms.

For the foregoing reasons, we limit our claim construction to the term "support wires" and adopt Hickory's definition: "support wires' require that the wire be a continuous strand of wire which may be formed "by butt-welding, end to end, shorter segments of wire." (R. 50, Def.'s Post-Markman Hr'g Br. at 2.)
In the present case, L & P contends that the term "support wires" includes an assembly of separate wires welded together. In sum, L & P argues that "support wires" are merely the wires that absorb any vertical load on the bedding foundation. Because the invention depicts welds joining the wires to support a vertical load, L & P's proposed claim construction would consider the entire '064 assembly a single wire.

At the outset, the claim recites "support wires" in the plural, thus requiring more than one welded "support wire." The specification does not set forth any definition of the term "support wires." Instead the specification describes "support wires" in language that tracks closely the claim language. '064 Patent, col. 1, ll. 44-49. The specification does, however, refer to a number of other wires -- for example, a border wire and connector wires. Thus, the specification distinguishes support wires from other types of wire. The specification identifies these separate wires as performing different functions, such as connecting or forming a border. When discussing welds to join separate wires, the specification retains the distinguishing name and identity of each joined wire. See, e.g., '064 Patent, col. 3, ll. 3-5. Finally, the specification expressly refers to "support wire ends," which attach to the border wire. '064 Patent, col. 2, ll. 57-59. Because the figures depict the support wires stretching from one border to the other, the specification suggests that the support wire ends attach only to the borders. The specification does not mention any support wire ends other than those attached to the border wire. Thus the specification does not discuss a "support wire" composed of multiple wires welded together and, consequently, having a number of ends.

Turning to the prosecution history, the '064 patent application issued without any amendments. Stating the reasons for allowance, the examiner detected three main differences between the '064 invention and the three prior art references. None of these differences addresses "support wires" made of two or more wires welded together. In sum, the district court correctly construed the term "support wires" to mean "a continuous strand of wire" with "only two ends."

B. Term 3: A support yoke (as used in claims 1 and 23).

Lutron contends that Term 3 means "A structural frame." Control4 contends the term means "A support structure, separate from the housing, that is mechanically secured to the housing and is designed to be fastened to the wall box."

Claims 1 and 23 state the following regarding the support yoke: "a support yoke coupled to the housing, the support yoke having a fastening device for coupling the yoke to the electrical wall box." Control4's proposed construction seeks to include all aspects of the quoted phrase in its definition of "a support yoke." The parties, however, did not ask the Court to construe the entire phrase. They only asked the Court to construe "a support yoke." Lutron states it is "A structural frame," while the initial phrase in Control4's construction states it is "A support structure."

Although the proposed definitions are similar, Lutron uses words other than the words that are being defined. Because this helps to explain and define the term more fully, the Court adopts Lutron's construction.

2) "Supported along its entire length by the upper edge of the front portion of said band"

Tecnol contends that "the plain meaning of "along its entire length" is that the chin brace must be in contact, from one end to the other, with the upper edge of the front portion of the band." [TAB at 23]. Tecnol contends that this claim language excludes collars which exhibit any gaps between the chin support brace and the neck encircling band. The Court rejects this construction, and notes with approval the following persuasive commentary by our fellow court in the District of Rhode Island, which has had occasion to construe this aspect of the '219 patent:

"Supported upon its entire length" does not mandate constant contact. "Support" does not mean the same thing as "constant contact." Therefore, an item made out of an inherently stiff material, such as the hard plastic from which these collars are made, is "supported along its entire length" without constant contact, and the presence of gaps does not alter that
support. Thus, constant contact is not called for by the patent claims.

**D. Supported by**

The phrase "supported by" is recited two times in Claim 1 as "a pair of side grate tables each supported by a corresponding one of said vertical supports . . ." and "a lower grate shelf supported by said scissors operator located beneath said horizontal work surface . . ." Plaintiff submits "borne or held up through contact with a member" as its construction of the term. Defendant submits "structural assistance, directly or indirectly" as its construction.

Figures 1 and 2 clearly demonstrate that the grate tables 214 and 216 are supported by the vertical support structure 188 and 202, respectively. Additionally, Figures 1 and 2 demonstrate that the grate tables 214 and 216 are attached to, connected to, or fastened to the middle frame of the structure at 114 and 124. The grate shelf (166) is supported by the scissors operator at 164 and 162. According to Figures 1 and 2 and the specification, Column 6, lines 1 through 4, and Column 6, lines 10 through 15, the lower grate shelf is mounted upon and directly underneath various portions of the structure. The ordinary meaning of a term cannot be viewed in a vacuum but must be examined in the context of the patent's written description. DeMarini Sports, Inc., 239 F.3d at 1324. When there is doubt about the meaning of a claim term, the Court is to look to the specification for guidance. North American Vaccine, Inc., 7 F.3d at 1576. Everything in the patent description demonstrates that "supported by" means somehow connected with or in contact with. There is no mystery here regarding indirect or direct contact. Defendant has not directed the Court to one piece of intrinsic evidence in support (no pun intended) of its definition.

Thus, the Court construes the phrase "supported by" as: Borne or held up through contact with a member.

**C. Claim 6**

41 Claim 6 adds: "The exposure apparatus of claim 4, wherein the exposure device is supported by the main frame." Id. at 8:6-7. Included in the parties' claim construction charts -- but not in their briefs -- is a dispute regarding the meaning of "exposure device." Questions regarding this term were not included in the parties' lists of proposed terms and claim elements for construction, and ASML has objected to Nikon's tardy addition of this claim. According to ASML, however, Nikon now agrees that "exposure device" does not require construction. The court finds Nikon's failure to brief construction of "exposure device" indicative of this agreement, and the court refrains accordingly from construing the term.

The parties' dispute the meaning of the term "supported by" as that term is used in claim 6. At the core of the parties' disagreement is the question of whether "supported by" connotes one structure bearing part or all of the weight of another structure or entity or if, by contrast, there is no weight support whatsoever.

Plain meaning offers substantial guidance here. As the court reads the relevant claim language, "supported by" connotes the holding, propping, or bearing of another item, and the language of the specifications is not to the contrary. In no fewer than four places, in fact, the specifications use a form of the word "support" to imply the bearing of weight: "Stage 10" is discussed as "supported on a conventional rectangular base structure," see Patent '500 at 3:43-45; "the window frame guide..."
structure" is depicted as "supported on horizontal surfaces of fixed guides 46A and 46B," id. at 5:11-14; "base support structure 80 is supported by its own support pillars or other conventional support elements," id. at 5:17-18; and "the photolithography apparatus" is placed on "supporting base structure 100." Id. at 6:1-2. Each of these specification sections implies, if not more, that some or all of the weight of one structure or item is borne by another, and ASML's unconvincing attempts to read weight-bearing out of the term are not to the contrary. 42 Consistent with plain meaning, the court finds that "supported by" connotes the bearing of some weight, and the court thus construes the term to mean "held, propped, or with weight borne by."

42 In support of its claim construction, ASML discusses a person leaning against a wall: "If a person stands on a floor and leans against the wall," ASML contends, "the floor and the wall both provide support [but] the wall . . . does not bear the person's weight." As a matter of physics, this is not necessarily correct in every case; depending on a host of variables (e.g., angle of incidence), the wall may in fact bear some of the leaner's weight, particularly if--as in ASML's definition--some of the support is from "below."

4032

4. nib supported by said housing

The term "nib supported by said housing" appears in claim 1 and claim 12. Chip-Mender asserts that it means "nib confined to said housing." Sherwin-Williams argues that it means a "nib in contact with the housing that may or may not be confined to the housing and/or be non-removable." The parties dispute the meaning of the phrase "supported by." They also dispute whether the nib is removable from the housing or not.

Chip-Mender contends that "supported by" means "confined to," based on the specification--"The nib is preferably constructed to confine the nib to the housing yet permit the nib to slide or float." '299 patent, col. 2, ll. 5-7. Chip-Mender argues that there is no suggestion in the patent that the nib is removable, and asserts that the applicator would not work if the nib were removed, because the paint would flow out of the reservoir and through the passageway and onto the floor if the nib were not there to stop it. Chip-Mender also refers to the prosecution history, and its cancelled claim 26 ("[t]he method of using a sealed paint applicator of claim 12 for the purpose of applying said paint composition of claim 18 to repair the painted surface of the vehicle"), and argues that this cancelled claim shows Russo's intent that the applicator be "sealed" by the nib, which is therefore not removable.

In opposition, Sherwin-Williams asserts that Chip-Mender is attempting to alter the plain meaning of a term ("supported by") through substitution of a narrower term ("confined to"). Sherwin-Williams contends that the plain meaning of "nib supported by said housing" does not require the nib to be "confined" by a housing, and that the term should be construed as also permitting the nib to be removed from the applicator. Sherwin-Williams claims that Chip-Mender is attempting to rewrite this claim term by importing a preferred embodiment from the specification.

Sherwin-Williams notes that the '299 patent uses both "support" and "confine" to describe how the nib is housed in the paint applicator. The specification states; "A nib is also found in the present invention, and is slidably supported by the housing. The nib is located in the passageway which communicates with the reservoir. The nib is preferably constructed to confine the nib to the housing yet permit the nib to slide or float." '299 patent, col. 2, II. 3-7 (emphasis added). Sherwin-Williams contends that this language discloses that any and all paint applicators described in the '299 patent have a nib that is "supported" by a housing, but that some of those applicators could be further enhanced--i.e., "preferably constructed"--to "confine" the nib in the housing. Sherwin-Williams claims that a person skilled in the art would not view "supported" nibs as synonymous with "confined" nibs, but rather, would view "confined" nibs as a sub-set of "supported" nibs.

With regard to Chip-Mender's citation to the prosecution history, Sherwin-Williams contends that it is impermissible to pursue a claim construction that is equivalent to a cancelled claim. Sherwin-Williams cites Schilder-Schroth Co. v. Cleveland Trust Co., 311 U.S. 211, 61 S. Ct. 235, 85 L. Ed. 132, 1941 Dec. Comm'r Pat. 802 (1940), for the proposition that
a patentee is not "free to gain the supposed advantage of the rejected claims by a construction of the allowed claims as equivalent to them." Id. at 221-22. Sherwin-Williams asserts that "this axiom was recently reaffirmed" in Omega Eng'r. Inc. v. Raytek Corp., 334 F.3d 1314 (Fed. Cir. 2003).

The court finds that "nib supported by said housing" means "nib held in place by said housing." In the portion of the specification cited by the parties, the nib is first described as "slidably supported by the housing" and as "located in the passage way which communicates with the reservoir." '299 patent, col. 2, ll. 3-5. The nib is then described as "preferably constructed to confine the nib to the housing yet permit the nib to slide or float." Id., col. 2, ll. 5-7. The use of the word "preferably" in this portion of the specification does not necessarily identify "confined to the housing" as a preferred embodiment, while allowing for alternative embodiments such as "removable from the housing." "Preferably constructed" refers not just to "confine the nib to the housing," but to the conjunctive, "confine the nib to the housing yet permit the nib to slide or float."

Descriptions of the invention that appear in the specification section are relevant to the construction of the patent. See SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1342-43 (Fed. Cir. 2001). Read together with the previous two sentences, which describe the nib as "slidably supported by the housing" and as "located in the passageway" (which passageway is located inside the housing), with no addition of the word "preferably," these portions of the specification lead to the conclusion that the reference in claims 1 and 12 to a "nib supported by said housing" simply means that the nib is held in place by the housing.

Moreover, there is no indication anywhere in the claims or the specification that the nib is "removable," and Sherwin-Williams has offered no compelling support for its own proposed construction of "nib supported by said housing" as meaning "nib may not be confined to the housing and/or be non-removable." Indeed, the nib would be unable to perform the functions required of it--sealing the applicator and regulating paint flow--if it were removable.

Finally, the court is not persuaded by Chip-Mender's argument that the court should look at cancelled claim 26 as part of the prosecution history, to establish Russo's intent that the nib be confined in the housing. 3 The prosecution history is silent with regard to the Examiner's reasons for cancelling claims 23-26, and the Federal Circuit disfavors using ambiguous comments or silence on the part of the examiner or the patentee as evidence to support any particular construction of a claim term. See Omega Eng'r. Inc. v. Memorex Prods., Inc., 415 F.3d 1278, 1286 (Fed. Cir.), cert. denied, 126 S. Ct. 829, 163 L. Ed. 2d 707 (2005). Moreover, the applicant's disclaimer must be clear and unambiguous. See Omega, 334 F.3d at 1325-26. The Supreme Court's decision in Schriber-Schroth is not to the contrary. See 311 U.S. at 218 ("Where the patentee in the course of his application in the patent office has, by amendment, canceled or surrendered claims, those which are allowed are to be read in light of those abandoned and an abandoned claim cannot be revived and restored to the patent by reading it by construction into the claims which are allowed."). Here, Russo did not amend, withdraw, or cancel any claims after his initial response to the Examiner's notice of claim rejections.
2. Support and movement

The parties next dispute what it means for the locking member to be "supported by the second end of the housing so as to permit movement of the first end of the locking member between a first position and a second position." Col. 7, lines 33-37. More specifically, the parties dispute the meaning of the preposition "by" in this context. Donaldson argues that under the claim the locking member must be supported in a specific manner to permit a particular type of movement, i.e., that the locking member must be mounted to the housing to allow pivoting around a pivot point in the second end of the housing, as embodied by the flange in the preferred embodiment. EPC argues that the claim language cannot be so limited and that all that is required is that the locking member be supported in a manner that allows movement of its first end.

The word "support" means, inter alia: to carry or bear the weight of; to hold in position; to prevent from falling, slipping, or sinking; or, to hold up. See, e.g., Webster's New World Dictionary, 2d ed. (1970); The American Heritage Dictionary, New College Ed. (1976). Under the claim limitation, that support is provided by the second end of the housing. Thus, the second end of the housing must hold the locking member in position, thereby preventing it from falling or slipping, in a manner that permits movement of the first end of the locking member between a first position and a second position. The claim language itself, then, is quite broad -- that the support provided by the second end of the housing permit movement between a first and second position -- and at issue is whether, as Donaldson contends, the specification or prosecution history mandate a more restrictive interpretation.

Applying standard claim construction rules, the Court is disinclined to restrict the claim language in the manner proposed by Donaldson to read additional limitations into the claim. As an initial matter, the Court notes that at the Markman Hearing in this case there was considerable disagreement between the parties as to the meaning of "pivot" as used in the specification. The Court need not resolve that dispute here, however, as there is nothing in the specification to indicate the patentee's intent to limit the meaning of "movement" to the particular pivoting movement selected for the preferred embodiment. The single reference to "pivoting" is found in the Description wherein, discussing the reset process, the patentee writes that "this will cause the locking member [# 96] to pivot, about the flange [# 104], from its cocked, off-center position, shown in Figs. 3 and 4, to a vertical position where the notches [# 98] can no longer engage the notches [# 100]." Col. 6, lines 13-16. It is well-settled that limitations from the preferred embodiment may not be imported to more broadly-worded claim language unless there is a clear indication that the patentee was acting as his own lexicographer to impart a novel meaning to a term. See e.g., KCJ Corp., 223 F.3d at 1356. There is nothing to suggest that this is such a case and, accordingly, the Court will not take the drastic step of effectively limiting the definition of "movement" to "Pivot." Consequently, the Court holds that the disputed language requires only that the second end of the housing holds the locking member in position, in a manner that allows for the first end of the locking member to move between a first and a second position.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

27 Donaldson's references to the prosecution history to support its position are inapposite. The cited exchanges between Mr. Nelson and the PTO are not directed to the "support" limitation but rather to the shape of the locking member and its "operation in progressively changing and maintaining" its relative lockup position. That the version of the claim in the specification subsequently approved included more detail regarding the pivoting action in the resetting means does not mean that inclusion of such language was necessary to approval of the amended claims. In light of this ambiguity, the Court does not find that the prosecution history evinces the patentee's clear intent to surrender any device which did not include a pivoting mechanism. See, e.g., Standard Oil, 774 F.2d at 452 (holding that prosecution history limits claim only when patentee clearly takes position before PTO such that competitor would reasonably believe the applicant had surrendered the relevant subject matter).

4034

2. "Supported Loosely"

Plaintiff contends that the claim term "supported loosely" in claim 11 of the '946 patent means "having just enough force applied for holding in position and to keep from falling, but not substantially more." (Doc. # 26-2, at 26). Plaintiff relies on
dictionary definitions to support its proposed construction.

In opposition, defendant asserts that the claim language means "receive substantially no tension." (Doc. # 26-2, at 27). Defendant refers the Court to the '946 patent specification, which states that "the hinge plates 56 receive substantially no tension from the elongate plate 32 . . . ." (Doc. # 1-2, '946 patent, col. 6, lines 35-37). Additionally, defendant refers the Court to the prosecution history, whereby the patentee repeatedly states that "[n]o substantial spring force is needed from the cover plate 32 to drive the hinge plates 172 to a fully open or closed position, or to hold them closed." (Doc. # 26-4, at 12, 59; # 26-5, at 26).

As stated above, claims "must be read in view of the specification, of which they are a part." Vitronics, 90 F.3d at 1582 (citations omitted). Therefore, the '946 patent specification and prosecution history support defendant's proposed construction. As such, the Court finds that "supported loosely" in the '946 patent means "receive substantially no tension."

4035

This construction also informs and is directly applicable to ascertaining the proper meaning of the two previously-mentioned limitations: "said plate members being supported on and extending transversely between said opposing surfaces of said side members . . . ." Id. at col.6 l.24-26 (emphasis added). The central issue to resolve concerning the first limitation is whether the plates are supported exclusively by the opposing surfaces of the side members - a position advanced by CPT - or, as IKN contends, in conjunction with the upper edges of the frame. To resolve this dispute, I must turn to the specification. The "Description of the Invention" section expressly states the longitudinally extending grooves, which are positioned on the opposing inner surfaces of the sidewalls, "serve as longitudinally extending guide profiles for supporting the plate members." Id. at col.4 l.36-37 (emphasis added). Furthermore, the specification also provides:

the plate members have on each of their lateral edges a longitudinal flange designed to cover the upper edge of an associated side member. The longitudinal flanges rest, during insertion of the plate members into the longitudinal guide profiles, on the upper edges of the associated side member to cover the upper edge of the side member.

Id. at col.3 l.9-15. From the two portions of the specification previously quoted, a person of ordinary skill in the art would understand the support for the plate members as deriving solely from the longitudinal guide profiles located on the inner surfaces that oppose one another. Therefore, I will construe the phrase "supported on . . . said opposing surfaces" to mean "the plate members are held up and in position and their weight is borne by the surface of each of the two side members that faces or looks toward the corresponding surface of the other side member."

10 IKN's argument is premised on a construction of the term "opposing surfaces" that includes the upper edge of the side members.

4036

IV

The next challenge by Leopold relates to the jury's finding that Roberts does not infringe claim 16 of the '427 patent or any claim of the '592 patent. Leopold's arguments on appeal relate exclusively to claim construction.

The court construed the claim language "having a fine grain filter media supported on said underdrain laterals" as requiring that the filter media sit directly on the porous cap. Leopold argues that the filter media need only be "above the porous cap and supported by the porous cap either directly or with the assistance of intermediate elements." We conclude that the district court properly construed the claim language.
The original purpose of the porous plate was to increase the volume of fine grain media in a filter system by permitting the removal of the course media that previously separated the fine media from the underdrain. That purpose is indicated throughout the patent's written description, and even appears later in claim 16, where the claim states: "said body further having pores which are sized so that said body supports said fine grain filter media without said media penetrating therethrough . . ." Furthermore, this interpretation is consistent with the ordinary meaning of the term "supported on," and nothing else in the patent or its prosecution history points to a different meaning.

The court also determined that the claims require that mixing of air and water occur in the underdrain blocks and distribution chambers (below the porous plate). Roberts's accused system apparently keeps the backwash air and backwash water separated until they are finally intermixed in the filter media above the porous plate. Leopold contends that because claim 16 requires only that "backwash fluid" be discharged from the underdrain block into the media, there is no requirement that mixing occur before the discharge into the media. Again, we agree with the district court.

Particularly relevant to this issue are statements made to the examiner during prosecution. In a response to an office action, Leopold stated: "The distribution chamber of the present invention facilitates intermixing of backwash gas and backwash liquid." Leopold then distinguished its invention from the cited references (Buffle and Davis) by arguing that the prior art chambers were not distribution chambers as claimed by Leopold because their underdrains were designed to separate air and water below the cap, and mixing took place only in the filter media. This statement indicates to a person reading the prosecution history that Leopold did not intend its patent to cover systems, like Roberts's, in which the air and water mix in the filter media.

Because we reject Leopold's arguments regarding claim construction and because Leopold makes no other arguments relating to infringement, we cannot say that the jury's finding of noninfringement is unsupported by substantial evidence.

iii. Supporting a pair of lenses

Plaintiffs construe the phrase "supporting a pair of lenses" to mean "holding the lenses in place, either by rims or some other retaining mechanism such as screws or pins." Defendant interprets the phrase to mean "holding the lenses in place using rims."

Read in the context of the claim language, it is obvious that the phrase "supporting a pair of lenses" is intended to describe a function of the "retaining mechanisms." Consistent with the above finding that "retaining mechanism" is a means-plus-function claim that is therefore limited to the embodiments in the specification, the court finds that "supporting a pair of lenses" means "holding the lenses in place using rims."

a. supporting portion

LGD contends that a "supporting portion" should be construed as a projection from the frame. D.I. 376 at Exh. Q-1. AUO contends that the "supporting portion" should not be limited to a projection, which may be defined to have a specified shape. Id.

The Court adopts AUO's construction of "supporting portion" as "any structure protruding from the frame (including but not limited to a cylinder or a cuboid) intended to support the optical film." '157 patent, col. 2, ll. 61-62, col. 3, ll. 4-12, col. 4, ll. 17-24, Fig. 2A and 2B; col. 6, ll. 4-8, 31-42 Fig. 3A and 3B; Fig. 3C, col. 7, ll. 39-45, Fig. 4A-4D.
iii. Supporting (respectively auxiliary) primary lenses therein

Not surprisingly, both Plaintiffs and Defendant construe the phrase "Supporting (respectively auxiliary) primary lenses therein" in ways that are consistent with their differing interpretations of the term "frame." Plaintiffs interpret the phrase to mean "the lenses are secured to the frames, whether rimmed or rimless," while the Defendant would require lenses secured to frames that include rims.

Consistent with the court's construction of the term "frame," which was based in part on its construction of the word "therein," the court interprets "Supporting (respectively auxiliary) primary lenses therein" to mean that "lenses are secured to frames that include rims.

Aspex argues that "said arms and said first and second magnetic members supporting said auxiliary spectacle frame on said primary spectacle frame" means "the arms and the first and second magnetic members maintain the auxiliary spectacle frame in position on the primary spectacle frame so as to keep the auxiliary spectacle frame from falling, sinking, or slipping." Ps. Br. 13. E'Lite posits that this claim limitation means "the arms contacting the primary spectacle frame and the first and second magnets being magnetically engaged to support the auxiliary spectacle frame." D. Br. 18.

The principal difference between the parties' proposed constructions is whether claim 18 requires the auxiliary frame arms to physically contact the top side of the primary frame's extensions. Under Aspex's proposed construction, claim 18 permits the magnetic engagement between the magnetic members to provide the sole support for securing the auxiliary frames to the primary spectacle frames. E'Lite contends that claim 18 requires that the contact between the auxiliary frame's arms and the top portion of the primary spectacle frame's extensions contribute to the support of the auxiliary spectacle frames along with the support provided by the magnetic engagement of the magnetic members.

Aspex relies on the doctrine of claim differentiation to support its proposed construction. First, Aspex maintains based on the claim language alone that claim 18 does not require that the arms of the auxiliary spectacle frame physically touch the top side of the primary frame. Second, Aspex argues that claims 1, 19, and 20 all contain the express limitation that the auxiliary frame arms rest on top of the primary spectacle frame, thus contributing to the support of the auxiliary frame to the primary frame along with the support provided by magnetic engagement. To support this argument, Aspex cites the court's construction of claims 1 and 2 of the predecessor patent, the '207 patent.

In Aspex the court held that claim 1's 16 reference to the auxiliary frame arms' "being engaged with and supported on said upper side portion of said primary spectacle frame" implied the limitation that the auxiliary frame arms must physically touch the upper side portion of the primary spectacle extensions. Aspex, 2001 U.S Dist. LEXIS 2088, 2001 WL 204775, at *4. Aspex posits that, because relevant portions of claims 19 and 20 17 contain almost identical language to claim 1, claims 19 and 20 likewise contain the same "physical contact" limitation. Thus because some of the '545 patent's claims expressly limit the connection between the auxiliary frame and the primary frame to require the auxiliary frame's arms to physically rest on the top portion of the primary frame's extensions, this limitation should not be imported into a claim that lacks the same limiting language.

Footnotes

16 The court notes that claim 1 in the '207 patent is the same in the '545 patent.

17 Claim 19 states, in pertinent part: "an auxiliary spectacle frame including two arms for extending over and engaging a corresponding top side of said side portion extensions." D. App. 9. Claim 20 states, in relevant part: "an auxiliary spectacle frame including two arms for extending over and engaging a corresponding top side of said extensions." D. App. 9.
Based on the doctrine of differentiation, the court begins its construction of this limitation of claim 18 by presuming that the "physical contact" limitation in claims 1, 19, and 20 is not present in claim 18. The court presumes that claim 18 encompasses two embodiments: (1) where the arms and upper side of the primary frame physically contact, and the magnetic members engage but do not contact; and (2) where the arms and upper side of the primary frame do not contact, and the magnetic members do contact. This construction is presumptively correct, but it may be rebutted by other intrinsic evidence.

E'Lite argues that multiple statements in the specification overcome this initial presumption. In the background of the invention, the specification distinguishes the '545 patent from two similar eyeglasses patents. D. App. 7. After briefly describing the prior art, the patentee asserts:

[i]n both of the [prior art] eyeglasses, the auxiliary lenses are simply attached to the frames by magnetic materials and have no supporting members for preventing the auxiliary lenses from moving downward relative to the frames such that the auxiliary lenses may easily move downward relative to the frames and may easily disengage from the frames when the users conduct jogging or jumping.

D. App. 7. It can reasonably be implied from this assertion that, in the '545 patent, the auxiliary lenses are not supported (i.e., prevented from moving downward relative to the frames) merely by magnetic engagement. Rather, the '545 patent employs supporting members (arms) that assist the magnetic members in supporting the auxiliary frame.

The '545 patent's summary of the invention ("Summary") states that the invention contains an "auxiliary spectacle frame including two side portions each having an arm extended therefrom for extending over and for engaging with the upper portion of the primary spectacle frame." D. App. 7. The Summary also states that "arms [of the auxiliary frame] are engaged with and supported on the upper portion of the primary spectacle frame so as to allow the auxiliary spectacle frame to be stably supported on the primary spectacle frame." Id. The language of the quoted statements is almost identical to the portions of claims 1, 19, and 20 that Aspex (and this court in Aspex) previously acknowledged as requiring the auxiliary frame's arms to physically rest on the upper side of the primary frame's extensions. The only significant difference in the use of this restrictive language is that, in the Summary, unlike in claims 1, 19, and 20, the '545 patent applies this "physical contact" limitation to the invention as whole. Global statements about the invention have particular interpretive weight. See Bard, 388 F.3d at 864.

The '545 patent's detailed description of the preferred embodiment likewise contains a global statement about the invention's requiring that the top side of the primary frame's extensions physically support the auxiliary frame's arms: "It is to be noted that the arms 21 are engaged with and are supported on the upper portion of the primary spectacle frame 10 such that the auxiliary spectacle frame 20 may be stably supported and secured to the primary spectacle frame 10." D. App. 7. The auxiliary frame arms could not be "supported on" the upper portion of the primary spectacle frame unless the two were in physical contact. The '545 patent's figures, especially FIG. 7, corroborate the description of the preferred embodiment. D. App. 5-6.

The intrinsic evidence is sufficient to overcome the presumption created by the doctrine of claim differentiation. See Inpro, 450 F.3d at 1355-56 ("Claims are construed in light of the specification of which they are a part."). These statements in the '545 patent's specification support the conclusion that claim 18 requires auxiliary frame arms to physically rest on the upper side of the primary frame's extensions, so that the upper sides of the primary frame's extensions support the auxiliary frame in addition to the support provided by the magnetic attraction of the magnetic members. Aspex challenges E'Lite's reliance on "the only disclosed embodiment" of FIG. 7, contending that the number of disclosed embodiments is not determinative of the meaning of the disputed claim terms. The court is not relying, however, on the number of embodiments for its construction of this limitation. Independent of the '545 patent's one embodiment, the global statements in the '545 patent's specification support this construction.

not requiring the arms of the auxiliary frame to contact the extension of the primary frame. Id. 2003 U.S. Dist. LEXIS 26355, [WL] at *12. This court respectfully disagrees with the reasoning of Miracle I because, in reaching its conclusion, the Miracle I court did not take into account any of the critically important global statements in the '545 patent's specification concerning the auxiliary arms' contact with the extensions of the primary frame. Id.

Therefore, the court construes this disputed limitation of claim 18 to require that the upper sides of the primary frame's extensions must physically contact the arms of the auxiliary frame. This physical contact thus supports the auxiliary arms in place in addition to any support coming from the engagement of the magnetic members. Because the remainder of the limitation is not seriously disputed, and since E'Lite's proposed construction is much closer to the original language of the limitation (with the exception of the physical contact limitation), the court adopts E'Lite's proposed construction with some additions to particularize the kind of physical contact required between the auxiliary frame arms and the primary spectacle's extensions. Accordingly, the court construes "said arms and said first and second magnetic members supporting said auxiliary spectacle frame on said primary spectacle frame" to mean "the arms contacting the upper side of the primary spectacle frame's extensions and the first and second magnetic members being magnetically engaged to support the auxiliary frame."

4. "Supporting the housing of the microprocessor in position relative to said docking connection means so that the single connector on the housing is coupled with said additional connection provided in the docking connection means"

Independent claim 17 is a method claim directed at interfacing a microprocessor with a plurality of peripheral devices. Subpart (e) of independent claim 17 recites the step of "supporting the housing of the microprocessor in position relative to said docking connection means so that the single connector on the housing is coupled with said additional connector provided in the docking connection means." ’645 pat., col. 10, Ins. 35-39. Plaintiff argues that this phrase should be construed according to the ordinary meaning of the words used: the housing is supported and the single connector on the housing couples or mates with the connector on the docking module. Plt.'s Opening Br., dkt. # 84, at 15.

Defendants contend that claim 17 should be construed to require that the docking connection means holds the portable computer in a vertical position. They argue that subpart (e) of claim 17 should be construed as "supporting the housing of the microprocessor in a vertical position relative to the docking connector." Dfts.' Opening Br., dkt. # 86, at 18. In support of their construction defendants turn again to the prosecution history. They contend that the applicants waived any claim to a physical orientation of the housing other than vertical in order to obtain the '645 patent. Plaintiff contends that this construction is inappropriate because it ignores the plain language of claim 17 and violates the doctrine of claim differentiation. Plaintiff notes that independent claims 1 and 14 contain a vertical orientation limitation but independent claim 17 does not. Defendants contend that claim differentiation is inapplicable because claim 17 has a different scope from claims 1 and 14 because claim 17 is a method claim whereas claims 1 and 14 are apparatus claims.

I start with the language of the claims. Subpart (e) of claim 17 requires that the housing of the microprocessor be supported such that the single connector on the housing couples with the connector on the docking connection means. As defendants concede, there is no explicit language in claim 17 requiring the housing to be held in a vertical position relative to the docking connection means. In contrast, claims 1 and 14 require "a support holding the housing in a vertical position." ’645 pat., col. 8, In. 55; col. 9, In. 65.

Turning to the prosecution history, defendants note correctly that, in the June 15, 1992 response to the patent examiner, the applicants distinguished their system from the patent issued to Herron in part by emphasizing that

the microprocessor housing drops into the docking module in such a manner as to permit the two connectors to mate. The docking module also has a support which holds the housing in a vertical or upright position to keep the connectors mated. It is simply the weight of the housing pressing down on the docking module which maintains the connection.

Aff. of Vito Canuso, dkt. # 87, exh. F, at 14. The applicants trumpeted the vertical orientation of the housing as an advantage because it reduced "the footprint of the system on the desk top. Id. at 15. In contrast, the Herron patent disclosed a docking module "which is latched to the rear of a laptop computer. The computer and docking module both rest on a desk top." Id. at

- 4702 -
16. Thus, "the computer in Herron is not oriented vertically as in the Applicants' system." Id. at 17.

It is clear that the vertical orientation of the housing when resting in the docking module was one of the novel features of the applicants' system. However, as I noted in discussing the laptop exclusion, the applicants made it clear in the June 15 response that they were not incorporating all of the novel features of their invention into every independent claim in the patent. Instead, they stated only that each independent claim contained at least one point of novelty. Id. at 16. In the case of the laptop exclusion, it is not obvious which of the independent claims contain the exclusion because none of the independent claims contain language explicitly excluding laptop computers. Therefore, the only way to incorporate the limitation into the patent is to infer that it is inherent in the terms "portable computer" and "portable computer microprocessing system."

The situation is different with respect to the vertical orientation limitation, however. I need not infer that that limitation is inherent in all of the independent claims because the applicants indicated clearly which of the independent claims contain this novel feature. Claims 1 and 14 require "a support holding the housing in a vertical position." Claims 17 and 20 do not contain this limitation. Therefore, defendants are not persuasive when they argue that of the prosecution history supports the importation of a vertical orientation limitation into claim 17.

Defendants do not concede the point easily. They argue that where an applicant makes statements during the course of prosecution that limit the scope of his invention as opposed to specific embodiments thereof or claims in his patent, those statements apply to all of the claims in the patent. For support, they cite Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335 (Fed. Cir. 1998). That case concerned a patented method for capturing, storing and displaying fingerprint images. At issue in that case was the claim term "slice data." The defendant argued that this term should be construed to mean data with an "active area" while the plaintiff argued that a "slice" encompassed more than an "active area." Id. at 1346. The court of appeals adopted the defendant's construction. It noted that the word "slice" was used "synonymously with 'active area' in two instances in the written description." Id. Also, the court looked to the prosecution history. In response to a rejection by the patent examiner, the applicants in Digital Biometrics added the word "slice" to one of their claims and distinguished their invention from prior art by Ruell with the following remarks:

"Unlike the applicants' claimed invention, there is no provision for generating the composite array as a function of overlapping image portions of the finger. Similarly, Ruell does not teach a system which identifies active portions of the image which are representative of the fingerprint features as a mathematical function of the stored data, and generates the composite array as a mathematical function of the data representative of the identified active portions."

Id. at 1347 (emphasis in original). Instead of limiting these remarks to the claims in which the term "active area" appeared, the applicants had made them with respect to all of the claims that had been rejected. Accordingly, the court of appeals held that the limiting construction in the remarks applied to all of the claims that had been rejected. Id.; see also Honeywell International, Inc. v. ITT Industries, Inc., 452 F.3d 1312, 1318 (Fed. Cir. 2006)(limiting term "fuel injection system component" to fuel filter in part because patentees had referred to "invention" as fuel filter at four points in specification).

At the claims construction hearing in this case, defendants argued that the present case was analogous to Digital Biometrics because in both cases the applicants discussed distinguishing characteristics of their inventions, not specific claims or embodiments thereof. This is true up to a point. Although the applicants for the '645 patent discussed their "system" as having a docking module that held the housing in a vertical position in the June 15 response, they also made it clear that all of the points of novelty highlighted in the response were not present in all of the independent claims. The prosecution history is useful in determining how the applicants and the patent examiner understood the claims, Phillips, 415 F.3d at 1317, but it is inappropriate to import a limitation from the prosecution history into a claim whose language will not support that limitation. Sofamor Danek Group v. Depuy-Motec, 74 F.3d 1216, 1220 (Fed. Cir. 1996).

Accordingly, I will adopt plaintiff's proposed construction of the phrase "supporting the housing of the microprocessor in position relative to said docking connection means so that the single connector on the housing is coupled with said additional connection provided in the docking connection means." That phrase will be construed to mean that the housing is supported and the single connector on the housing couples or mates with the connector on the docking module.
c. "supports for . . .", "a reinforcement structure . . ."

As with the previous phrases, these phrases describe sufficient structure. See '677 Patent, cl. 1 ("within said vending machine such that the dispensing ends of said trays are aligned generally within a vertical plane adjacent said front panel of the vending machine . . . secured to said trays adjacent said dispensing ends thereof for maintaining dimensional width tolerances across the dispensing end of the tray in a manner that prevents bending distortion of the tray at said dispensing end thereof."). The claim language does not use the term "means," and the court concludes that "supports for operatively mounting said trays within said vending machine" and "a reinforcement structure secured to said trays . . ." are not subject to § 112, P 6.

Each of the fourteen asserted claims of the '815 patent contains a limitation which describes the portion of the device which stabilizes the flexible flail as having or including "a generally planar surface." It is apparent to the court, after review of the extensive briefing and after viewing an example of the accused device during oral argument, that such an element is not present in defendants' products.

The feature of accused devices that plaintiff alleges infringes his '815 patent is the open wire edge guide piece that extends radially from the center of the trimmer housing. This wire piece originates on the housing and extends horizontally from both sides straight out from its mounting; each side then bends downward for a short distance; and the sides then bend outward again, meeting and terminating in a shape resembling the letter "u." As noted, the wire piece is open at all points and most importantly so at its terminating "u"-shaped end. It is this end section which plaintiff claims acts as the flail stabilizing "surface." 5

5 Also, the wire edge guide can be "flipped" up against the trimmer housing when the trimmer is not being used for edging.

Giving words their ordinary and customary meaning, the court concludes that this wire edge guide does not have a "surface" so as to bring it within the claim limitations of the '815 patent. The dictionary definitions of "surface" include "the exterior face of an object" or "a material layer constituting such an exterior face." Webster's II New College Dictionary 1109 (Rev. 2001). Further, "surface" means "the outer face, outside, or exterior boundary of a thing" or "part or all of the boundary of a solid." The Random House College Dictionary 1322 (1st ed. 1980).

As noted, the crucial "u"-shaped portion of the wire edge guide on the accused trimmers is open, having only a void of space above, below, and within its perimeter. The wire piece has no exterior face or layer. The court concludes that this open structure simply does not constitute a "surface" as that term is commonly understood.

This construction makes sense given the flail-stabilizing purpose of plaintiff's device. An exterior boundary or the face of a solid would indeed -- as is claimed -- provide an area against which the spinning flail could "bump" or touch, thereby limiting its deviation from its rotational path and providing a more accurate edge cut. In contrast, the accused wire edge guide lacks this feature. Indeed, defendants assert that the wire edge piece on their trimmers is not intended to stabilize the flail at all, merely to serve as an edging guide.

Given this plain meaning of this claim limitation, the court concludes that further construction of the '815 claims is unnecessary, as is a Markman hearing. See Ballard Medical Products v. Allegiance Healthcare Corp., 268 F.3d 1352, 1358.
The court having concluded that the accused devices lack the "surface" limitation of all asserted claims of the '815 patent, defendants are entitled to summary judgment thereon. 6

6 The court also notes that the accused devices lack the dual function "guide/guard" element of claims 24, 25, 27, 28, 37 and 38, which are written in "means-plus-function" form as permitted by 35 U.S.C. § 112, P6. In order to infringe this "means-plus-function" limitation, the accused device must, at a minimum, include some element or means for performing the "dual function" of "guiding said flexible flail means along said reference surface while shielding a user from debris generated by" the flexible flail during use. It is undisputed that the allegedly infringing feature of the Black & Decker trimmers -- the open wire edge piece -- is incapable of shielding the user from debris generated by the flail as it trims or edges.

4044

Second, claim 1 of the '813 patent requires that each club in the correlated set have a head with a face for impacting a golf ball, a back surface, a heel portion, a toe portion, and a "sole having a trailing edge extending between heel and toe portions." (Id., col. 7, lines 43-44.) Further, "at least a central portion of said trailing edge [is] indented toward said face at least 1/16 of an inch." (Id., col. 7, line 45 to col. 8, line 2.) The claim states that the "lower portion of said back surface adjacent said trailing edge," (id., col. 8, lines 2-3), is specifically described as "sloping upwardly and inwardly from said indented trailing edge toward said face." (Id., col 8, lines 5-6.)

1. The Properly Construed Meaning of "Adjacent":

Cleveland argues that the '813 patent specifications provide intrinsic evidence of which surface adjacent said trailing edge is claimed in the patent. Specifically, Figures 5 and 11 of the '813 patent show the lower back surface area, labeled as 60, as adjacent to the trailing edge. Further, the patent specifications describe in detail the relationship between the sole, trailing edge, and the adjacent surface of said trailing edge, the acute angle formed between the plane of the sole of the club head and the inwardly sloping lower back surface 60. In sum, Cleveland argues that the '813 patent specifications prevent Karsten from advocating a broad definition of the claim term "adjacent" which is unsupported by the intrinsic evidence.

While Karsten failed to be its own lexicographer and define "adjacent," as used in the claim language of the '813 patent, the '813 patent does contain diagrams depicting the invention. Rather than rely on the diagrams contained in its own patent, Karsten argues that this Court should look to extrinsic evidence to define the claim term "adjacent." According to Karsten, the dictionary definition and diagrams submitted by Karsten as exhibits to its Response Memorandum provide the correct definition of the claim language used by Karsten in the '813 patent.

Karsten has failed to reconcile or distinguish the intrinsic evidence contained in its own patent which indicates that "the surface adjacent said trailing edge" must be a back surface. For this Court to read the claim language of the '813 patent broadly enough to validate Karsten's interpretation we would be required to ignore the intrinsic evidence in favor of extrinsic evidence. While a patent's claim language is not necessarily limited to the disclosure contained in the specifications and drawings, the specifications and drawings are persuasive absent other clarifying language. The intrinsic evidence requires this Court to interpret the claim language "surface adjacent said trailing edge" as a back surface and the specifications and drawings support this interpretation.

4045

The Adjacent Back Surface
Karsten states that the district court erroneously identified the "back surface" as used in claim 1, and that this error led the court to misconstrue the meaning of "sloping upwardly and inwardly," resulting in an erroneous construction of these terms that excluded the Cleveland clubs. Karsten argues that "the lower portion of said back surface adjacent said indented trailing edge" is the encircled area 60, indicated by dashed line 59 in Figure 4 of the '813 patent:

[SEE FIGURE 4 IN ORIGINAL]

The district court construed the "back surface adjacent said indented trailing edge" as excluding the surfaces of the cavity. This construction is in accordance with the description in the specification that the "back surface" that is adjacent to the indented trailing edge circumscribes but does not include the cavity surfaces. The court was correct in rejecting Karsten's proposed construction, which departs from this description.

The district court also required that "the surface adjacent said indented trailing edge [must] slope upward and inward" relative to the trailing edge and the face of the club. Karsten states that it was incorrect to interpret "sloping inwardly" as relative to the trailing edge and the club face, instead of relative to the ground when the sole of the club is placed horizontally on the ground. However, the specification describes the lower back surface area as sloping inwardly and upwardly from the trailing edge as shown in Figures 5, 7, and 9, which illustrate these parameters relative to the trailing edge and the hitting face, not the ground. The district court's claim construction correctly reflected the description in the specification, and is confirmed.

4046

1. Disc-Shaped Member with surface indicia integral with said planar surface

Claim 1 is limited to a "disc-shaped member" comprised of, in part, "a major surface having a planar surface area and a plurality of spaced-apart, elongated, discrete surface indicia integral with said planar surface area . . ." (Col. 5, lines 27-30). As construed in this court's prior memorandum order, the term "surface" may refer to the surface of an unfinished plastic disc-shaped substrate. (D.I. 558 at 10-11) Given this interpretation, the term "surface indicia" is not limited to any specific type of "surface indicia" such as "transparent microgrooves" or surface indicia with a partial metal coating.

DMI's CDs contain pits which are "formed within a [plastic] substrate underneath a continuous metal coating and a plastic protective coating." (D.I. 347 at 4) DMI argues that its CDs do not infringe claim 1 because the pits are buried below the surface of the disc and therefore cannot be called "surface" indicia. (D.I. 347 at 22) DMI has admitted, however, that the "pits" in its CDs are formed at the surface of a plastic disc-shaped substrate. Accordingly, the claim limitation of a disc-shaped member with surface indicia integral to the planar surface of the disc-shaped member covers DMI's CDs.

4047

7. "Tear-wettable surface layer"

The plaintiff proposes "a surface layer, as defined below, which has an outermost surface on which tear fluid has a tendency to spread when it contacts that surface. Further, "surface layer" means "the exterior portion of a contact lens that is chemically distinct from the lens body. This layer extends from the outermost surface of the contact lens to a depth in the lens where the composition, including proportion of components, becomes substantially the same as the overall composition of the lens body. A contact lens that has substantially the same overall polymer composition does not contain a surface layer under this definition, even though part of the polymer can re-orient in response to certain environmental conditions." The defendants propose "a layer which covers the entire lens body, which has a measurable thickness and which has a surface that is contacted by the tear layer and which has a high affinity for the tear layer." The Court will construe the phrase as two separate terms, "tear-wettable" and "surface layer."

a. "Tear-wettable"
The parties dispute whether this term means "a high affinity for" tears or whether it means that tear fluid spreads out when exposed to a surface. The plaintiff contends that "tear-wettable" means "tear fluid has a tendency to spread out when exposed to a surface." According to the plaintiff, its construction is the meaning understood by one of ordinary skill in the art in the context of this patent. The defendants argue that "tear-wettable" requires that tears directly contact the surface layer and, therefore, the surface layer must have a high affinity for tears. In the context of this patent, the Court adopts the plaintiff's construction of "tear-wettable."

b. "Surface layer"

The prosecution history provides the proper guidance for construction of this term. The relevant portion of the prosecution history reads:

[In applicants' invention there is justification for describing the overall lens as having a "body" portion and a "surface layer" because their compositions actually differ. The "surface layer" is simply any layer beginning from (i.e., including) the outermost surface and moving inward to any arbitrary depth of the lens, with the "body" of the lens just being all the remainder of the lens. Amendment, April 20, 1992, at 8-9.

There is nothing in the intrinsic evidence that requires the "surface layer" to cover the entire lens body or to have a "measurable thickness." Accordingly, the Court construes "surface layer" to mean "a layer beginning from, and including, the outermost surface and moving inward to an arbitrary depth of the lens, and having a different composition from the 'body' portion of the lens."

DuPont thereby cites to specification language providing a relatively clear definition of the term at issue. The specification refers to the thermally removable layer functioning as "a layer which alters the surface characteristics of the photosensitive element." (859 Patent at col. 9, lines 62-63.) This Court accordingly construes "surface modifying layer" as meaning "a layer that alters the surface characteristics of photosensitive element."

Surface mount light elements

The term "surface mount light elements" appears in the '823 patent; "surface mount semiconductor light elements" appears in the '302 patent. Because of the "semiconductor" limitation in the '302 patent, Litepanels contends that two separate constructions are needed for each term. Gekko proposes the following construction for both terms: "light component designed to be soldered to a surface of a circuit board."

Regarding the '823 patent, the specification states that an advantage of the "surface mount" is the heat dissipation capabilities, "particularly as compared to non-surface mount LEDs which tend to dissipate heat typically through their leads." '823 patent, Col. 24:34-36. It teaches that using surface mount light elements provides a "larger and more direct heat conduction path to the mounting surface." Id. at Col. 24:37-38. While the specification describes the advantages of surface
mounts, it does not provide a clear definition of the term.

Because the specification lacks clear guidance on the meaning of "surface mount," both Gekko and Litepanels based their proposed constructions on the Wiley Electrical and Electronics Engineering Dictionary's ("Wiley Dictionary") definition of "surface mount." The Wiley Dictionary defines surface mount as "a technology for mounting components and devices in which the connections are soldered to a surface, as opposed to having leads which pass through said surface." Wiley Electrical and Electronics Engineering Dictionary (2004).

When reading the advantages described in the specification together with the definition of "surface mount," Gekko's proposal is too broad. Gekko's construction excludes a key portion of the definition: "as opposed to having leads which pass through said surface." Gekko argues that the Wiley Dictionary's definition does not require the substrate to appear without holes; however, the specification contemplates otherwise. As discussed above, one of the main advantages of surface mounts are the increased heat dissipation because of the increased contact to the mounting surface. '823 patent, Col. 24:34-36. These advantages would be greatly diminished, and possibly nullified, if holes were drilled into the surface. Therefore, reading the claim in light of the specification of which it is a part, Gekko's proposed construction is improper.

Litepanels proposes the phrase means "a light emitting element where the electrical leads are designed to be soldered to a surface of a circuit board, rather than mounted through a hole in the circuit board." The first part of Litepanels's proposed construction tracks the Wiley Dictionary's definition. The second part of Litepanels's construction ties the specification in with the definition by excluding through-hole mounts.

Because the specification teaches the advantage of surface mounting is the lack of holes, the construction needs to include that limitation. Thus, the Court construes "surface mount light elements" to mean "a light emitting element where the electrical leads are designed to be soldered to a surface of a circuit board, rather than mounted through a hole in the circuit board."

The '302 patent claims contain a "semiconductor" limitation. As a continuation of the '823 patent, the '302 patent contains the same discussion of "surface mount" advantages. Gekko's universal construction removes the "semiconductor" limitation present in the '302 patent claims, which impermissibly broadens the claim language. Therefore, the Court construes "surface mount semiconductor light elements" to mean "a semiconductor light emitting element where the electrical leads are designed to be soldered to a surface of a circuit board, rather than mounted through a hole in the circuit board."

A. "a surgical device" ('753 patent) and "an implant" ('290 patent)

9) The specification explicitly addresses only surgical devices. See, e.g., D.I. 70, Ex. B ('290 patent) at Title; D.I. 70, Ex. A ('753 patent) at Title; id. at 1:38-39 ("The present invention relates to surgical devices such as implants or suture fastenings."); 1:63-64. "When a patent thus describes the features of the 'present invention' as a whole, this description limits the scope of the invention." Verizon Servs. Corp. v. Vonage Holdings Corp., 503 F.3d 1295, 1308 (Fed. Cir. 2007) (citations omitted).

10) In addition, the prosecution history reveals that Dr. Bonutti disclaimed stents in order to overcome a rejection over Dr. Palmaz's '417 patent by the Examiner:

    Palmaz discloses an expandable intraluminal vascular graft, or expandable prosthesis for a body passageway (col. 6, lns. 21-23). . . . Applicants, on the other hand, disclose, inter alia, an assembly for use in surgical applications in humans. . . . An almost limitless number of surgical devices can be constructed in accordance with the present invention. D.I. 70, Ex. M at 5-6.

Dr. Palmaz used the terms "intraluminal vascular graft" and "expandable prosthesis" in the '417 patent to refer to his invention of the balloon-expandable stent. Having disclaimed stents in the prosecution history, Dr. Bonutti is not entitled to capture them through claim construction. Springs Window Fashions LP, 323 F.3d at 994 (citations omitted) ("It is well established that 'the prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was..."
disclaimed during prosecution."); see Computer Docking Station Corp., 519 F.3d at 1379; Gillespie, 501 F.3d at 1291; Ormco Corp., 498 F.3d at 1314, 1316; Chimie, 402 F.3d at 1384.

11) MarcTec argues that the terms "surgical device" and "implant" cannot limit the scope of the claims because they are part of the preamble. This argument is flawed; terms in the preamble can, and often do, limit claims. "Whether to treat a preamble as a limitation is . . . 'resolved only on review of the entirety of the patent to gain an understanding of what the inventors actually intended and intended to encompass by the claim.'" In re Cruciferous Sprout Litig., 301 F.3d 1343, 1347 (Fed. Cir. 2002) (quoting Corning Glass Works, 868 F.2d at 1257); Poly-America, L.P. v. GSE Lining Tech., Inc., 383 F.3d 1303, 1309 (Fed. Cir. 2004).

12) The term "surgical device" is "a fundamental characteristic of the claimed invention that is properly construed as a limitation of the claim itself." Poly-America, L.P., 383 F.3d at 1310 (citation omitted). Here, "the specification is replete with references to the invention as a [surgical device], including the title of the patent itself." Id. "Surgical device" is used in the first sentence of the Abstract and the first substantive sentence of the specification. This phrase "is used repeatedly to describe the preferred embodiments." Id. The specification does not disclose any non-surgical devices. "To read the claim in light of the specification indiscriminately to cover all types of [devices] would be divorced from reality." Corning, 868 F.2d at 1257.

13) Second, the preamble language is limiting because Dr. Bonutti relied on it to distinguish prior art. Cruciferous Sprout, 301 F.3d at 1347 (preamble limiting where used to distinguish prior art). When Dr. Bonutti's claim language was rejected because of Palmaz's invention of the balloon-expandable stent, Dr. Bonutti made it clear that his invention was limited for use in conventional surgery and did not cover non-surgical devices such as stents. D.I. 70, Ex. M at 5. Dr. Bonutti made this argument to distinguish Palmaz's stents from proposed claim 11 (now claim 1), directed to "a surgical device for implantation into a body," and proposed claim 27 (now claim 11), directed to "an implantable device for implantation in a human patient." Id. at 2-4. Dr. Bonutti's statements to the Patent Office show a "clear reliance by the patentee [on the "surgical device" and "implant" requirements] to persuade the Patent Office that the claimed invention is not anticipated by the prior art." Cruciferous Sprout, 301 F.3d at 1348. Where - as here - a patentee relies on the preamble to distinguish the prior art, the preamble is a claim limitation. Invitrogen Corp. v. Biocrest Mfg., L.P., 327 F.3d 1364, 1370 (Fed. Cir. 2003) ("'[C]lear reliance on the preamble during prosecution to distinguish the claimed invention from the prior art transforms the preamble into a claim limitation because such reliance indicates use of the preamble to define, in part, the claimed invention.'") (citation omitted).

14) With regard to "implant," MarcTec also argues that excluding stents is inconsistent with dependent claims that are directed to a device "positionable in a vessel" or "conformable to a vessel." But many surgical implants are positionable in or conformable to a vessel without being stents. Examples include vascular grafts, used to replace or connect vessels during conventional surgery, see, e.g., D.I. 91, Ex. Z (U.S. Patent No. 4,300,244) at 1:10-14, as well as heart valves, which are surgically implanted and are positioned in or conform to a vessel, see D.I. 91, Ex. AA (U.S. Patent No. 4,689,046). See also D.I. 91, Ex. BB (U.S. Patent No. 4,483,339) (a vascular surgery roll for use in vessel to allow for easier suturing). Furthermore, similar claims were already in existence when Dr. Bonutti distinguished surgical devices, see, e.g., D.I. 70, Ex. M at 4, and cannot be used to broaden claims that were limited to avoid the prior art.

15) Consistent with the claim language, the specification, and the prosecution history, the Court construes "a surgical device" from claim 1 of the '753 patent as meaning "a device for use in surgical applications, but not including an expandable intraluminal vascular graft or expandable prosthesis for a body passageway."

16) Consistent with the claim language, the specification, and the prosecution history, the Court construes "an implant" from claim 1 of the '290 patent as meaning "a device for use in surgical applications, but not including an expandable intraluminal vascular graft or expandable prosthesis for a body passageway."
2. A "surgical procedure" means treatment of disease, injury and deformity by operation or manipulation.

b. '314 patent, claim 1, element 1: "a surgical reference device defining a three-dimensional space;"

The Court construes this element to cover a device used to define three-dimensional space. The claim provides structure ("a surgical reference device"), and teaches what this structure must do ("define three-dimensional space.") While the specification teaches that a stereotactic frame is a reference device commonly used with one embodiment of the beam localization and microscope embodiments of the invention, see '314 patent, Fig. 1; '314 patent; '314 patent, col. 8, ll. 48-56; '314 patent, col. 13, ll. 52-58, the Court would improperly read an extraneous limitation into the language of claim 1, element 1 if it concluded that the reference device in all embodiments must only be a stereotactic frame. Such a conclusion would also be contrary to the specification's description of alternative embodiments using an articulating robotic arm or infrared or ultrasonic sensors to define three-dimensional space. See '314 patent, col. 14, ll. 22-37 & Figs. 38 & 39 (describing robotic arm) 25; '314 patent, col. 14, ll. 34-37 (describing use of sensors). 26 Defendants' interpretation would exclude these embodiments from coverage; such an interpretation is rarely, if ever, correct. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996).

Unlike most of the other claims and elements at issue in this case, this element is not in means-plus-function form. Accordingly, the scope of its protection is not limited by the corresponding structure in the specification. However, the element must still be construed in light of the specification.

Plaintiff's expert (the inventor of this device) explains that positional devices contained within an articulating robotic arm can be used (and were previously used) in frameless stereotaxy to define stereotactic space. See Declaration of Tyrone Hardy at PP10, 12 (Ct. Rec. 302).

See Hardy decl. at P10 (explaining that infrared or ultrasonic sensors can be used in place of robotic arm to define three-dimensional space).

The plaintiff proposes "extending around." The defendants propose "covering the entire lens body." The plaintiff argues that its proposal is consistent with the commonly understood meaning of the term and that the defendants' proposal is not supported by the specification or the prosecution history. The defendants argue that the specification characterizes the tear-wettable surface as "coating" and as a "layer." According to the defendants, this implies that the surface layer is continuous.
and, therefore, should cover the entire lens body.

This term does not have a technical meaning in the context of this patent and can be understood according to its plain and ordinary meaning. The Court, therefore, declines to construe this term.

GO BACK

4055

(4) Surrounding and Around

The parties next dispute the meaning of the claim terms "surrounding" and "around" as used in the '842 and the '211 patents. Claim 1 of the '842, quoted above, uses the term "surrounding"; claim 13 of the '842 uses the term "around"; claim 13 discloses:

[a] method of attaching a current or voltage bayonet to a circuit board, comprising:

providing a circuit board with at least one opening adapted to receive a bayonet;

forming a plurality of vias around said at least one opening;

placing an electrically conducting bayonet in said at least one opening;

applying solder on one surface of the circuit board, through the vias to the opposite surface of the circuit board and extending to said bayonet.

U.S. Patent No. 6,186,842 B1, col. 7, lines 52-62.

Square D contends that "surrounding" and "around" both mean "located on the perimeter of" and EI contends that they both mean "completely enclosing all sides." As Square D correctly pointed out at the Markman hearing, construing these terms as EI suggests would actually preclude at least one of the preferred embodiments described in the specification. That is not appropriate. See, e.g., Oatey Co. v. IPS Corp., 514 F.3d 1271, 1276-77 (Fed. Cir. 2008)(ordinarily, absent a clear disclaimer in the specification or prosecution history, it is inappropriate to interpret claim terms in a way that excludes embodiments disclosed in the specification). See also Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed Cir. 1996). Accordingly, the Court rejects EI's construction, and adopts Square D's construction, which is consistent with the specification, as well as the ordinary meanings of these words. The Court construes "surrounding" and "around" to mean "located on the perimeter of."

F. Claim language to be construed from Claims 3 and 6 -- "sheathing surrounding a major portion of the length of said tube" -- col. 4, ll. 49-50; col. 6, ll. 51-52

HEN's proposes to construe the claim language "surrounding a major portion of the length of said tube" to mean "covering a section of the tube sufficient to protect the tube." (HEN CC Br. at 25.) Minco, on the other hand, proposes to construe this claim language to mean that "the sheathing must cover more than 50% of the conductive tube." (Minco CC Br. at 38.)

We construe "surrounding a major portion" to mean "covering a significant portion." In this instance, we believe that a person of ordinary skill in the art in question would understand that the term major portion refers to a significant portion, such as a portion of the tube sufficient to protect the functional integrity of the measuring device. We reject Minco's contention that a major portion must mean that the sheathing merely surrounds more that 50%. Had the claim stated that the sheathing surrounds the majority of the conductive tube, then we would agree with Minco that more than 50% of the tube must be covered by the sheathing. We also reject HEN's proposed construction that the sheathing must cover a section of the tube sufficient to protect it. HEN's proposed construction is derived from the following language in the specification:
"[s]heath 2 is tapered along a major portion of its length toward the immersion end 3 for protecting the tube 1 and for minimizing the ability of gasses to be trapped adjacent the measuring elements 5 and 6." (Minco Ex. A., col. 2, ll. 61-64.) However, the use of the word "major" in this instance refers to the portion of the sheath that is tapered, and not to the portion of the tube covered by the sheath.

1. "Surrounding" the "Leading End"

In support of non-infringement, Bridgeport first argues that its connector, which includes an adaptor that encloses the intermediate portion but not the shoulder of the connector, does not "surround[]" the "leading end" of the connector, as required by all claims of Patents '050 and '164:

[A] hollow electrical connector through which an electrical conductor may be inserted having a leading end thereof for insertion in a hole in an electrical junction box; a circular spring metal adaptor surrounding said leading end of said electrical connector which has a leading end, a trailing end, and an intermediate body ….

(Doc. 83, Exs. A, B (emphasis added)). To construe this phrase, the court will analyze its two elements, "surrounding" and "leading end," separately.

"Surrounding," as defined by Webster's Third New International Dictionary, means "to be situated or found around, about, or in a ring around" or "to cause to be encompassed, encircled, or enclosed with something." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 2302 (Philip Babcock Gove ed., 1993). Thus, "surrounding" is not necessarily limited to circumstances in which a force or thing completely envelopes--separating entirely from the outside--an individual or item. Rather, the term may be used more loosely to describe any situation in which an outer boundary significantly borders an underlying entity. See, e.g., id. ("The house [was] surrounded on three sides by a wide veranda").

Other claim language supports the broader interpretation of "surrounding" as significantly bordering, rather than completely encircling. Several claims require the "circular spring metal adaptor [to be] less than a complete circle when on the electrical connector," meaning that a part of the underlying connector is necessarily exposed through the gap in the adaptor. Further, because these claims dictate that the adaptor be held in place by the flange and shoulder, which is concededly part of the connector's "leading end" (Doc. 115 P 19), the adaptor cannot completely enclose the leading end of the connector. Consistency of interpretation across the claims demands that the term be imbued with its broader meaning. See Georgia-Pacific Corp. v. U.S. Gypsum Co., 195 F.3d 1322, 1331 (Fed. Cir. 1999). Accordingly, the court will construe "surrounding," as used in this context, as describing an adaptor that significantly borders the circumference of the "leading end" of the connector.

Examining the second aspect of the phrase, "leading end," Webster's Third New International Dictionary defines "leading" as "being in advance during normal … movement" and "leading edge" as "the forward edge of … something that itself moves." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 1284. While this definition conceivably refers to only the outermost extremity of the connector, as Bridgeport suggests, it could also reasonably mean a larger part of the end of the connector, including the entirety of the portion that is inserted into the junction box. Compare id. at 747 (defining "end" as "the extreme, ultimate, or most remote section") with id. (defining "end" as "the portion of an area … that lies at or by the termination").

The context of the phrase in the claims sections of the patents establishes that the latter interpretation is correct. The first
claim of both patents describes the "leading end" of the connector as the part "for insertion in [the] hole in [the] electrical junction box." Other claims, providing for an embodiment of the design for use with a threaded adaptor, require the adaptor to fit over a "threaded section of said electrical connector leading end," meaning that the "leading end" cannot refer only to the edge of the device but must include the length of the connector that is covered by the adaptor. Thus, the claim itself defines "leading end" as that portion of the connector intended for insertion into the hole of the junction box, not merely the outermost edge. 8

8 Clearly, it makes little sense to interpret the phrase "leading end" to refer only to the outermost portion of the connector—the top of the cylindrical connector and not the rounded sides—because, so interpreted, the "leading end" would include no spatial area that an adaptor could surround. Perhaps recognizing the illogical nature of this construction, Bridgeport focuses its argument on the premise that the patent documents provide an alternative, and more conceptually feasible, definition of the connector's "leading end" as its "raised shoulder"—the ridge extending around the circumference of one end of the connector. This interpretation, although deficient in other respects, would at least provide a surface on which the adaptor, and Bridgeport's contentions, could conceivably rest.

Attempting to overcome this interpretation, entitled to a "heavy presumption" of accuracy, see CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002), Bridgeport argues that the inventor provided an explicit definition of the phrase, trumping its otherwise plain meaning, in the following descriptive paragraph in the specifications section:

FIG. 4 illustrates a view of the zinc die-cast connector … with the spring steel adaptor … attached. The flange … is the trailing end and raised shoulder … is the leading end. They are shown holding the spring steel adaptor in place.

(Doc. 83, Exs. A, B (emphasis added)). However, this short description, neither relied upon nor repeated elsewhere in the specifications or the claims, lacks the "clarity, deliberateness, and precision [required] to impart an unaccustomed meaning to an otherwise clear claim term." K-2 Corp., 191 F.3d at 1364. The statement appears only in reference to a specific embodiment of the invention, and does not expressly limit the scope of other claims. Indeed, the patent itself disclaims such an intent by stating that the "descriptions [included in the specifications section] … should not be construed as limiting the scope of the invention but as merely providing illustration" and that "the scope of the invention should be determined by the appended claims and their legal equivalents rather than by the examples given." (Doc. 83, Exs. A, B). The proposed alternative meaning set forth by Bridgeport conflicts not only with the definition set forth in the claims themselves but also with the patent's directive to abstain from reliance on the specifications for the interpretation of terms. Thus, this meaning must be rejected in favor of the ordinary and customary construction of the phrase. 9 See Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998) ("The claim construction inquiry, therefore, begins and ends in all cases with the actual words of the claim, [and] … the resulting claim interpretation must, in the end, accord with the words chosen by the patentee to stake out the boundary of the claimed property."); SRI Int'l v. Matsushita Elec. Corp. of America, 775 F.2d 1107, 1121 n.14 (Fed. Cir. 1985) ("Specifications teach. Claims claim.").

9 Even assuming arguendo that this paragraph could reasonably be viewed as establishing a controlling definition of terms, the description does not support Bridgeport's proposed meaning. Language in the claim section, quoted previously, identifies the "connector" as having only a "leading end" and the "adaptor" as having "a leading end, a trailing end, and an intermediate body." The provision upon which Bridgeport relies describes a unit with both a "trailing end" and a "leading end," and, as such, must refer to the adaptor, which has both components, and not the connector, which has only a "leading end."

Further, accepting Bridgeport's contention that the specifications section defines the "leading end" of the connector as the "raised shoulder" would render certain terms of the claims superfluous. Claim 1 of Patents '050 and '164 requires all connectors to have a "leading end." However, subsequent claims dictate that the connector also include, in addition to the
limitations expressed in claim 1, a "flange and shoulder." (Doc. 83, Exs. A, B). Assuming Bridgeport's interpretation, it would be unnecessary to state in subsequent claims that the connector includes a shoulder since the term "leading end" would inherently include this element. Because Bridgeport's interpretation would render terms of the claims superfluous, it should be rejected in favor of a construction that gives meaning to all language. See Union Pacific Corp. v. United States, 5 F.3d 523, 526 (Fed. Cir. 1993). The phrase "leading end," as used in the claims at issue, refers to that portion of the connector that fits within the junction box. Thus, the court will construe the phrase "surrounding said leading end" as describing an adaptor that significantly borders the circumference of that part of the connector that fits within the junction box.

Applying this construction to the claims at issue, and viewing the facts in the light most favorable to Arlington, sufficient evidence exists to support Arlington's contention of literal infringement. The adaptor of Bridgeport's device extends around most of the circumference of the intermediate portion of the connector. Although the adaptor does not encompass the shoulder, it does encircle a significant part of the end of the connector intended "for insertion in [the] hole in [the] electrical junction box." These facts, if established at trial, support a finding of literal infringement, rendering summary judgment on these claims improper.

2. "a distal portion susceptible to electrolytic disintegration in blood . . . elongate tip portion not being susceptible to electrolytic disintegration in blood"

The parties dispute the proper construction of the phrases "susceptible to electrolytic disintegration in blood" and the opposite phrase "not susceptible to electrolytic disintegration within blood" as those phrases are used in Claim 21 of the '136 Patent.

The phrases "susceptible to" and "not susceptible to" are non-technical phrases which are commonly used in the English language. The commonly understood definition of "susceptible to" is "capable of being affected by." See Webster's New Twentieth Century Dictionary, 1837 (2d ed. 1983). A commonly understood meaning of "not susceptible to" is "being resistant to." The Court examines the written description for any use of the phrases. The phrase "not susceptible to electrolytic disintegration in blood" is used in the written description to refer to the characteristics of the material out of which the tip portion is constructed:

The tip portion is a long and substantially pliable segment and is comprised of a material not susceptible to electrolytic disintegration within blood.

('136 Patent, Col. 5:8-10.) There is no intrinsic evidence that these phrases are intended to have any specialized meanings. The Court finds that one of ordinary skill in the relevant art would give the phrases "susceptible to" and "not susceptible to" their ordinary and customary definitions.

The written description does contain a discussion of various materials and manufacturing processes which would make an embodiment susceptible or not susceptible to disintegration. However, the characteristics of a preferred embodiments may not be adopted as limitations on the apparatus as claimed.
14 In the Summary of the Invention and elsewhere in the written description, stainless steel is listed as a material which can be electrolytically disintegrated. (See '136 Patent, Col. 4:33-35.) A secondary coil 28 is disclosed in the written description made out of platinum, having particular diameter and specially shaped tip. (See '136 Patent, Col. 6:23-65.) Platinum is discussed as being resistant to electrolytic disintegration. [citation?]

The Court construes "susceptible to" as it is used in the phrase, "a distal portion susceptible to electrolytic disintegration in blood" in Claim 21 of the '136 to mean:

a distal portion of the core wire which has attributes which make the segment able to electrolytically disintegrate when submersed in blood.

Correspondingly, the Court construes "not being susceptible to" as it is used in the phrase "elongate tip portion not being susceptible to electrolytic disintegration in blood," in Claim 21 of the '136 Patent to mean:

an elongate tip portion which has attributes which make the portion resistant to electrolytic disintegration when submersed in blood.

6. A handle "suspended between adjacent corner pylons" and a "generally open area being defined below said handle," or a "handle structure that can be freely grasped about substantially the entire periphery thereof"

The '461 and '572 patents require that the handle be "suspended between adjacent said corner pylons" and also require the presence of a "generally open area being defined below said interior and exterior surfaces of said handle structure and between said interior surface of said handle structure . . .."

Rehrig asserts that the modifiers "generally" and "substantially" indicate that absolute openness below the handle and freedom to grasp the entire periphery of the handle are not required. Norseman contends that the plain language of the claim requires suspension of the handle, meaning "to hand so as to be free on all sides except at the point of support." The Court construes this requirement to allow for some minor deviation from absolute openness below the handle and some obstruction of the freedom to grasp the entire periphery of the handle. However, the Court also interprets this language to require that the structure not be supported from below in order to give some meaning to the term "suspended."

B.

The district court construed "a sweep angle that causes the blade to intercept the shock" to mean "a sweep angle in the outer region that is constant or decreasing." It further explained that this construction does not include forward sweep. The plain language of "a sweep angle that causes the blade to intercept the shock" leaves the properties of that claimed angle unclear. The district court found that one of ordinary skill in the art would have necessarily resorted to the specification to interpret "a sweep angle that causes the blade to intercept the shock."

This court construes "a sweep angle that causes the blade to intercept the shock" to mean "a rearward sweep angle in the outer region that is constant or decreasing" because the specification supports only rearward sweep. The specification states that the sweep angle is "nonincreasing (decreases, or at least does not increase) with increasing radius." '931 application col.4 ll.27-29. The invention emphasizes the critical character of the nonincreasing sweep angle in the tip region. '931 application col.4 ll.46-62. The parties agree that the sweep angle at the boundary between the intermediate and outer regions is a rearward sweep angle. If the outer region translates forward from rearward sweep to zero degree sweep, the sweep angle necessarily decreases. If, however, the outer region translates farther, from zero degree sweep to forward sweep, the sweep...
angle necessarily increases. For example, translating forward from twenty degrees rearward sweep to five degrees forward sweep would decrease sweep from twenty degrees rearward sweep to zero degrees sweep, then increase sweep from zero degree sweep to five degrees forward sweep. Because the invention of the '931 application specifies a nonincreasing sweep angle with increasing radius, this example shows that the invention did not contemplate forward sweep in the outer region.

UTC argues that five degrees forward sweep is actually negative five degrees rearward sweep, but the specification does not use negative signs to indicate forward sweep. For example, the specification describes translating the sweep angle from forward sweep to zero sweep as "nonincreasing (decreases, or at least does not increase)." '931 application col.5 ll.36-45. If, as UTC suggests, a negative sign could indicate forward sweep, then translating the outer region from forward sweep to zero sweep would be increasing--a direct contradiction of the requirements of the specification.

This court construes "a sweep angle that causes the blade to intercept the shock" from the point of view of a person of ordinary skill in the art. See Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005) ("It is the person of ordinary skill in the field of the invention through whose eyes the claims are construed."). The record shows that a person of ordinary skill in the art would consider translating beyond a zero degrees sweep angle to create a forward sweep angle as a total reversal of direction, rather than a mere "decrease" of the angle. This interpretation would remain correct even if negative signs indicated a forward sweep. Also, the record shows that translating the outer region toward the axial direction, as required by this court's construction of "translated forward," results in a completely unrealistic blade shape well before the sweep angle is reversed to a forward sweep angle. Therefore, a person of ordinary skill in the art would not understand claim 23 of the '931 application to cover forward sweep.

UTC argues that the specification of the '931 application supports its construction of "a sweep angle that causes the blade to intercept the shock" because it states that "the invention contemplates any blade whose airfoil intercepts the endwall shock to bring the passage shock into coincidence with the endwall shock." '931 application col.5 ll.2-4. To the contrary, the specification teaches that the sweep angle must be nonincreasing with increasing radius--a reading that cannot include forward sweep. See '931 application col.4 ll.27-29. The district court found that a person of ordinary skill would not have understood the specification to disclose a total reversal of direction from rearward to forward sweep. Interpreting the claim to encompass forward sweep would unreasonably broaden "a sweep angle that causes the blade to intercept the shock."

UTC argues that the prosecution history of the related '040 patent shows that "a sweep angle that causes the blade to intercept the shock" covers forward sweep in the outer region. The portions of the prosecution history of the '040 patent serving as a basis for UTC's argument state:

[A] preferred embodiment of the present invention's blade has a leading edge sweep angle that decreases in a tip region, or put another way, has a leading edge with a tip region that is translated in a direction opposite to that of the sweep of the leading edge intermediate region.

[N]one of the prior art . . . discloses or suggests a supersonic turbomachinery blade with a leading edge that is swept in one direction (rearward or forward) and a tip region that is translated in the other direction from its boundary with the intermediate region.

J.A. 7171-76. Again, this court does not read this prosecution history to include forward sweep. These passages do not discuss translating the blade so far forward as to reverse the direction of the sweep. This court will not unreasonably construe "a sweep angle that causes the blade to intercept the shock" to include forward sweep in the outer region based on unclear prosecution history particularly when the specification does not allow forward sweep.

UTC also presented extrinsic evidence of computational fluid dynamics (CFD) simulations conducted by its expert, Dr. Yuan Dong, to support its proposed claim construction. It argued that a person of ordinary skill in the art at the time of the invention who conducted a CFD analysis would have seen that under at least some conditions, forward sweep in the outer region was required to intercept the shock. As noted earlier, "the shock" referenced in claim 23 is endwall shock. The record shows that endwall shock is not visible in CFD simulations.

The record shows that one of ordinary skill in the art would not reverse the direction of the sweep angle without a clear
motivation to do so. As CFD simulations would not show endwall shock, those simulations would not make one of skill in the art think that claim 23 included forward sweep in the outer region. In addition, in Dr. Dong’s CFD simulations, he translated the outer region in the direction of the relative velocity vector, not toward the axial direction. Therefore, his simulations do not reflect the correct claim construction.

Dr. Dong also equated endwall shock and passage shock even though the specification states that they are unrelated. ’931 application col.1 ll.40-45. As endwall shock is not visible in CFD simulations, Dr. Dong translated the blade until it intercepted the passage shock. Because endwall shock and passage shock are located in different positions within the fan, translation forward to intercept the passage shock would not yield the same fan blade as translation forward to intercept the endwall shock. Thus, this court does not believe that Dr. Dong’s CFD simulations reflect the views of one of ordinary skill in the art in deciding to sweep the blade forward in the outer region to intercept the endwall shock. Moreover, this extrinsic evidence in no way overcomes the intrinsic evidence in the specification that excludes forward sweep in the outer region.

Defendant Ion Beam construes the term "switch" to mean "a device designed to close or open, or both, one or more electric circuits." (Ion Beam P.&A. at 28-29.) The court, however, implicitly defined the term already in its discussion of the term "switchyard." Microsoft defines the term as "a circuit element that has two states. (Airhart Decl. Ex. P. at 249.) The term switch is defined by the Oxford English Dictionary as follows:

Name for various mechanical devices for altering the direction of something, making a connexion or disconnexion, or other purposes. a. On a railway: A movable rail or pair of rails pivoted at one end, . . . b. In an electric telegraph, telephone, signalling-, lighting-, or other apparatus: A lever, plug, or other device for making or breaking contact, or altering the connexions of a circuit, . . . e. Computers. A program instruction that selects one or other of a number of possible paths according to the way it is set.

OXFORD ENGLISH DICTIONARY (2d ed. 1989). Accordingly, the term "switch" is hereby defined as "a device for altering the direction of something, in this case a beam, and selecting the onward path of the entity by choosing between at least two possible paths." (See Airhart Decl. Ex. H at 145; and Ex. N at 226; accord Rosenberg Decl. Ex. 3, the ’642 Patent at 6:14-17.)

Examining the scope of 3(C)(e) first, I find that its plain language, when read in light of the specifications, is not limited to a sliding mode selector switch. Claim 3(C)(e) reads that the audio recording and tape measuring system comprises:

a mode selector switch connected to the circuit controlling and processing means and movable between a RECORD and a PLAY mode, enabling the circuit controlling and processing means to establish the desired operation of the recording circuit.

Zircon argues that the language, "movable between a record and a play mode," requires a slide switch to be read into Claim 3(C)(e) because Claim 2(e), which also defines the mode selector switch, uses "selecting" instead of "movable between." I find that the specifications do not limit the term "movable between" exclusively to the action of a slide switch.

In making this determination, I have presumed that different language between claims signifies a difference in their meaning and scope and that I may interpret claims in light of the specifications that led to the patent. Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987). However, I note that I cannot read into a claim a limitation that appears only in a specification since the claim, not the specification, measures the invention. SRI Int'l. v. Matsushita Elec. Corp. of America, 775 F.2d 1107 (Fed. Cir. 1985). Furthermore, two claims which read differently may cover the same subject matter. Tandon, 831 F.2d at 1023.
The specifications state that the mode selector's preferred embodiment "comprises a slide switch which is movable... between a PLAY position and a RECORD position." This differs from the antecedent basis for Claim 2(e) which calls for a mode selector button for mode selection. Despite this difference I refuse to read a slide switch requirement into Claim 3(e) because the specifications also state that "various alternate switch configurations can be employed..." This specification language clearly indicates that Claim 3(C)(e)'s "movable between" language does not necessarily require a slide switch, but allows for other types of switches.

4063

A "Switch Lock"

Fellowes defines "a switch lock" in Claim 1, element 1(t), as "a device that prevents movement of the on/off switch." Michilin proposes that a "switch lock" is "a device located on the exterior of the housing of the shredder that prevents movement of the on/off switch." Intek merely urges the Court to find the switch lock to be "distinct and separate from an on/off switch."

Fellowes' view that the "switch lock" "prevents movement of the on/off switch" is supported by a plain reading of Claim 1, the summary of the invention and the specifications. Claim 1 teaches that the "switch lock" is movable from a "locking position wherein the switch is locked in the off position" to a "releasing position wherein the switch is released for movement from the off position." '559 Patent, col. 6, lines 54-57. See id. at col. 1, lines 26-28 ("One aspect of the invention provides a shredder with a switch lock that locks the on/off switch in its off position."); id. at col. 5, lines 3-8 (in order to activate the shredder, the switch lock "must first be moved to its releasing position, and then the switch 42 is moved to its on or reverse position. This reduces the likelihood of the shredder mechanism 16 being activated unintentionally.").

Michilin's argument that the "manually engageable portion" of the "switch lock" must be located on the exterior of the housing is rejected in that fashion and the reasons are set forth below in the construction of the terms "provided on the exterior of the housing," element 1(y). See Section 5. The only remaining issue is whether, as Intek submits, the "switch lock" is "distinct and separate" from "an on/off switch." Intek points to the word "a" before the term "switch lock," as well as the specifications and figures, as evidence that "a switch lock" is a "new element, different" from the "on/off switch." Intek Br. 23 (citing '559 Patent, figs. 1-3, 7-10). Intek may be correct that "a switch lock" and "an on/off switch" are "different" and provide "separate and distinct functions." Id. at 23-25. Yet although the "switch lock" provides a distinct service from the "on/off switch," it could not be separated from the "on/off switch," as it is manually operated to lock the "on/off switch."

The Court rejects Intek's construction for present purposes and FINDS that "a switch lock," element 1(t), is "a device that prevents movement of the on/off switch."

1. "Switchyard"

According to Claim 1 of the '581 patent, the technology at issue comprises a "radiation beam source, beam accelerator, plurality of treatment rooms and a switchyard for directing accelerated beam from the accelerator to a selected... treatment room[]." (Id. at 9:2-7.) Plaintiff relies on standard dictionary definitions to arrive at the following construction for the term "switchyard": "systems of devices by which the beam is transported along one of a plurality of paths." (Optivus P.&A. at 13:19-20.) Defendant, on the other hand, argues the patentees specifically defined the term "switchyard" in the patent specification. (Ion Beam Opp'n at 6:5-7.) Ion Beam relies on extrinsic expert testimony from Dr. Lennox to formulate its own definition: "[t]he set of transport line equipment including all switching magnets, dipole magnets, and quadruple magnets which direct the beam from the accelerator to delivery in the treatment room." (Ion Beam P.&A. at 14:3-5.) Once again, as in its construction of the claim terms at issue in the '287 patent, Defendant Ion Beam adopted a very narrow construction, limiting the patent at issue to a narrow set of highly specific parameters. (See id.) Plaintiff's rebuttal expert, Dr. Lundy, responds that the construction should not be limited to specific types of magnets as Dr. Lennox proposes.
Once again, the court turns first to the language of the claims and the common meaning of the claim terms before reviewing the specification to see if the patentees have specially defined any claim terms. Vitronics, 90 F.3d at 1582. "In construing claims, the analytical focus must begin and remain centered on the language of the claims themselves." Texas Digital Sys., 308 F.3d at 1202. "The terms used in the claims bear a 'heavy presumption' that they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art." Id. Dictionaries and technical treatises are always available to the court to aid in the task of determining meanings that would have been attributed by those of skill in the relevant art. See id. (citing Vitronics, 90 F.3d at 1584 n.6; and Cybor Corp., 138 F.3d at 1459.)

Random House Dictionary of the English Language ("Random House") defines "switchyard" as "a railroad yard in which rolling stock is distributed or made up into trains[.]" (Airhart Decl. Ex. H, p. 145.) Similarly, the American Heritage Dictionary (4th ed. 2000) defines the term as "[a]n area where railroad cars are switched and trains assembled." The Webster's New Universal Unabridged Dictionary ("Webster's Unabridged") defines "switchyard" as: "a railroad yard where cars are shifted from one track to another by means of a system of switches as in making up trains." (Airhart Decl. Ex. L. at 193.) The Oxford English Dictionary includes a similar definition, but adds the following: "an enclosed area of a power system which contains the switchgear." OXFORD ENGLISH DICTIONARY (2d ed. 1989). The definition found in the Oxford English Dictionary plainly indicates the "term" switchyard is equally applicable to a "power system," and not just locomotives. See id.

Turning to the patent specification, the description in the '581 patent teaches an "illustrated beam handling system . . . [that] also includes a switchyard 6 comprising four switching magnets 38, 40, 42, and 44." (Rosenberg Decl. Ex. 2. the 581 Patent at 2:40-43; see also Ex. 3, the '642 Patent at 4:47-48.) Figure 1 is a rendering of the entire system, including the switchyard. (Id. at p. 2.) The description recounts four switching magnets comprising the switchyard. Each has two states. (Id. at 2:40-45.) Figure 1 depicts the same. The switching magnets are arranged in a line with switching magnet 44 downstream from switching magnets 42, 40 and 38. (See, e.g., id. at p. 2, Fig. 1.) The beam leaves the synchrotron and encounters the first switching magnet, numbered 38. (See id.; id. at 2:40-50; see also Ex. 3 at 4:40-50) With the switching magnet in the first state, it will bend and deliver the beam to the first treatment station. (Id.; see also Ex. 3 at 4:52-55.) In the second state, the switching magnet will let the beam travel "downstream" to the next switching magnet in the switchyard. (Id. at 2:49-55; see also Ex. 3 at 4:52-55.) In other words, each switching station operates just like a switch on a train track - it either diverts the beam to a side track, or allows it to continue traveling down the same track toward a selected treatment room. (See id.) Accordingly, it is apparent that the term "switchyard" does not really have any special technical meaning in the context of the '642 patent. (See id.) It is akin to "a switchyard" as that term is generally understood.

Technical glossaries 15 confirm this conclusion. The Fermilab website defines "switchyard" as "a transfer beam line that will direct beam coming from the Main Injector to the Meson line in the fixed target area." Available at http://www.fnal.gov/pub/news03/definitions/switchyard.html. The Stanford Linear Accelerator Center ("SLAC"), originally constructed in 1962, defines the term "Switchyard" as follows: "When the electrons and positrons reach the end of the linac and enter the Beam Switch Yard (BSY), they are diverted in different directions by a powerful dipole magnet and travel into storage rings, such as SPEAR or PEP, or into other experimental facilities, such as Final Focus Test Beam (FFTB) or the arcs of SLC -- the SLAC Linear Collider." Available at http://www2.slac.stanford.edu/vvc/accelerators/bsy.html.

15 The court hereby takes judicial notice of the SLAC and Fermilab websites, and the technical glossaries embedded therein.

Turning to the extrinsic evidence supplied by Defendant Ion Beam, Dr. Lennox draws the court's attention (Lennox Decl. at P 42) to a Fermilab publication entitled Conceptual Design of a Proton Therapy Synchotron for Loma Linda University Medical Center (1986). (Rosenberg Decl. at Ex. 7.) That article includes the following definition: "The switchyard transports protons from the accelerator to the start of the individual dedicated beam lines leading to the separate beam-spreading systems. An element is defined to be a part of the switchyard if two or more treatment-room beam lines use it. Otherwise, the element will be part of a dedicated treatment-room beam line." (Rosenberg Decl. Ex. 7 at p. 68 of '74.) In light of this article, it is difficult to see how the term "switchyard" is being used any differently than the common dictionary.
The article simply describes a system where, like a train "switchyard," a single track of proton beams is fed into a "switchyard" where it then is diverted on to one or another track leading to one of the treatment rooms. 16 (See id.)

Accordingly, the court hereby finds the term "switchyard" to mean "a series of switches 17 that bend or otherwise divert the proton beam emanating from the accelerator in one of two directions; that is, the beam is either diverted toward a treatment station or sent on to the next switch in the yard."

APL contends that the proper construction of the term "swivel" is "a swivel that is separate from and rotates independently of the turntable." SBM does not dispute that the intrinsic evidence of Claim 1 requires that the swivel be separate from the turntable. Instead, SBM disagrees that there is anything that "requires" the swivel "to move differently from, or at a different time than, the turntable." The real question is whether the swivel and turntable are required to be able to move differently from each other and at different times, i.e., independent of each other.

An entry in the prosecution history for the '183 Patent states:

"By means of the arm 6, a moment can be exerted on the turntable 5 for rotation thereby of the vessel. Forces which act on the turntable do not affect in any way the connection of hoses 8 and 9. The turntable rotates independently of the swivel."

Extrinsic evidence supports APL's proposed construction. Dr. Leendert Poldervaart ("Dr. Poldervaart"), who had a role in the prosecution of the '183 Patent, was presented by SBM as its corporate representative for an oral deposition in this case. He testified that the swivel and the turntable have "independent bearing arrangements" and therefore "rotate independently from each other." Deposition of Leendert Poldervaart, at 48:18-49:4. Dr. Poldervaart also noted that in some circumstances the swivel and the turntable could rotate "in the same direction," "in opposite directions," and "completely independently from each other." Id. at 49:25-51:4.

The Court agrees with APL's proposed construction of the term "swivel" as it is used in Claim 1 of the '183 Patent.
4. Claim 11 ("swivel member")

Claim 11 (and all dependent claims) in the '286 patent uses the term swivel member in the following context: "An ultrasonic instrument according to Claim 10, wherein the coupling member includes a swivel member, the swivel member being positioned to permit rotation of the coupling member in relation to the movable handle." '286 Patent, Claim 11 (emphasis added). Plaintiff proposes construing the term as "component designed to permit swiveling or rotation of another part," whereas defendant proposes "a component that permits the coupling member to pivot freely."

The Court construes this term as: "A component designed to permit the coupling member to swivel or rotate." n8 First, this construction comports with the plain language of Claim 11, which expressly describes what the "swivel member" is designed to do. See '286 Patent, Claim 11 ("the coupling member includes a swivel member, the swivel member being positioned to permit rotation of the coupling member") (emphasis added); accord '286 Patent, 5:13-18 ("Swivel member 108 is preferably formed from molded half-sections 108a and 108b and permits rotation of the coupling member relative to movable handle 36."); 6:1-6 ("Referring to FIGS. 11-15, when movable handle 36 is pivoted clockwise about pivot member 82 towards stationary handle portion 28, in the direction indicated by arrow "A" in FIG. 11, cam slot 88 engages protrusion 90 of the swivel member 108 to advance coupling member 98 distally within cavity 110 of rotation knob."). Second, defendant's proposal of "pivot freely," instead of "swivel" or "rotate," imports a term that has no basis in the intrinsic evidence; the words "pivot freely" describe motion different from simply "swivel" or "rotate."

n8 While plaintiff argues that the swivel member permits the swiveling or rotation of "another part" instead of, specifically, the "coupling member," see Markman Tr. at 37, the Court does not see a basis for this construction in the intrinsic evidence. The claim language specifically provides that the swivel member permits rotation of the coupling member. While the coupling member may in turn permit rotation of the rotation knob, see id. at 37-38, it is the coupling member that interfaces with the swivel member. Accord id. at 38 ("The coupling member is sort of the interface between the swivel member and the rotation knob.").

4067

Swung Forwardly and Upwardly About A Transverse Axis

The second issue of interpretation is whether to swing "about a transverse axis" requires rotation about the axis or applies to fingers which are fixed upon the axis and bend in response to pressure. The Court finds that the bending of fixed flexible fingers does not constitute swinging about an axis. Swinging about an axis necessarily requires some pivoting or rotation at the axis. Plaintiff correctly points to dependent claim three which adds as a further element that "said fingers are individually mounted to [a rod] for swinging movement thereon," as evidence that this limitation is not contained in claim one. However, this limitation is far greater than a requirement for a hinge or pivot about the axis. It imposes limitations of a rod comprising the axis and individual free swinging fingers. This Court's interpretation of claim one does not incorporate these limitations.

4068

B. Merits.

Dataware contends the labels it manufactures and sells do not infringe on any claim of the '816 patent under 35 U.S.C. § 271(a). A literal patent infringement analysis involves two steps: the proper construction of the asserted claim and a determination as to whether the accused method or product infringes the asserted claim as properly construed. Markman v. Westview Instruments, Inc., 52 F.3d 967, 976 (Fed.Cir.1995), aff'd, 517 U.S. 370, 390, 134 L. Ed. 2d 577, 116 S. Ct. 1384(1996). Claim construction is a matter of law. Id. at 979. Here, in addition to literal infringement, EDP asserts Dataware's labels infringe the patent under the doctrine of equivalents, i.e., the Dataware label contains elements identical or equivalent to each claimed element of the '816 patent. See Warner-Jenkinson Co., Inc. v. Hilton Davis Chemical Co., 520 U.S. 17, 40, 137 L. Ed. 2d 146, 117 S. Ct. 1040 (1997). Although equivalents is a factual matter normally reserved for a fact
finder, the trial court should grant summary judgment where no reasonable jury could find equivalents. Id. at 39 n.8. I consider the motion for summary judgment on the grounds that the Dataware labels do not (1) literally infringe the claims of the '816 patent and (2) do not infringe the '816 patent under the doctrine of equivalents.

Dataware claims its labels do not infringe the claims of the '816 patent when properly construed. As stated, this involves an analysis of the proper construction of the asserted claim and a determination as to whether the Dataware labels infringe the asserted claim as properly construed. See Markman, 52 F.3d at 976. In determining the proper construction of a claim, there are numerous sources that may be utilized for guidance, including both intrinsic evidence (e.g., the patent specification and file history) and extrinsic evidence (e.g., expert testimony). Vitronics Corp. v. Conceptoronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). I look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and the prosecution history, as the most significant source of the legally operative meaning of disputed claim language. Id.

Dataware asserts its labels do not literally infringe the '816 patent because its alpha-numeric are all the same size, while an amendment to the patent specified that the alpha-numeric in one part of the EDP label be larger than those in another part. Dataware maintains the prosecution history of the patent bars EDP from arguing either (1) that the patent claims encompass labels in which the alpha-numeric are the same size or (2) that the human readable code may be expanded to encompass background color. On this second issue, Dataware points to dependent claims 2 and 8 which distinguish "human readable code" from "background color" in terms indicating the background color comprises a "third code." Dataware also points to language in the application in which EDP used the term "character" to distinguish prior art and explain the advantages of the size of different characters.

In response, EDP asserts factual disputes preclude summary judgment. EDP focuses on the term "symbols" in claims 1 and 7 of the '816 patent. The last paragraphs of these claims refer to "symbols of said human readable code," with larger symbols in the second horizontal row than such symbols in the first horizontal row. The allegedly infringing EDP FAST-SCAN TM label has smaller color blocks on top than on the bottom but the same size alpha-numeric.

EDP contends the term "symbol" is not defined in the patent and was not discussed by the Patent Office examiner or EDP's attorney during the prosecution process. Arguing the term is ambiguous, EDP provides extrinsic evidence, including the affidavit of expert Robert Sterne, to the effect that "symbol" is sufficiently broad to include color.

In reply, Dataware asserts construction of the claims of the '816 patent is a matter of law and not a factual issue precluding summary judgment. It states the claims are not ambiguous, citing a portion of Sterne's report in which he concluded the meaning of the claims of the '816 patent "is clear without any ambiguity." (Reply, Ex. A at P 35.) Finally, Dataware contends EDP is estopped from arguing the background colors are part of the symbols of human readable code because EDP's own prior art (the '674 patent) discloses the use of color blocks of different sizes. Dataware seeks a ruling that the symbols of human readable code in the '816 patent cannot be interpreted to include the background colors.

At the hearing on the motion, counsel agreed that, if the court were to decide that the term "symbols of human-readable code" in claims 1 and 7 does not include color, then there would be a finding of non-infringement, whereas concluding the term did not include color, would result in a finding of infringement. (Tr. Hearing Sept. 28, 1998 at 27-28.)

In interpreting the term "symbols of said human readable code," I first look to the words of the claims themselves to define the scope of the patented invention. See Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620 (Fed.Cir.1995). Although words in a claim are generally given their ordinary and customary meaning, a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history. Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1578 (Fed.Cir.1996) (holding "[a] technical term used in a patent document is interpreted as having the meaning that it would be given by persons experienced in the field of the invention, unless it is apparent from the patent and the prosecution history that the inventor used the term with a different meaning") (citations omitted).

Second, I review the specification to determine whether the inventor has used any terms in a manner inconsistent with their ordinary meaning. The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication. Markman, 52 F.3d at 979. "Claims must be read in view of the specification, of which they are a part." Id. The specification contains a written description of the invention which must be clear and complete enough to enable those of ordinary skill in the art to make and use it. Thus, it is always highly relevant to the claim construction
analysis. Usually, the specification is dispositive; it is the single best guide to the meaning of a disputed term. Vitronics, 90 F.3d at 1582.

Third, I may also consider the prosecution history of the patent, here in evidence. See Markman, 52 F.3d at 980. This history contains the complete record of all the proceedings before the Patent and Trademark Office, including any express representations made by the applicant regarding the scope of the claims and is often of critical significance in determining the meaning of the claims. Id. Included within an analysis of the file history may be an examination of the prior art cited therein. Vitronics, 90 F.3d at 1583.

In most situations, an analysis of the intrinsic evidence alone will resolve any ambiguity in a disputed claim term and, in such circumstances, it is improper to rely on extrinsic evidence. Id. In those cases where the public record, i.e., the claims, specification, and file history, unambiguously describes the scope of the patented invention, reliance on any extrinsic evidence is improper. Id.

The '816 patent specification states:

In general, the label of the present invention contains a message displayed in three codes. A first code is a machine readable code such as a bar code, a second code is in a human readable for showing letters and digits. A third code, consisting of background colors behind the human readable code, provides additional visual indication of sequencing of the media to which the labels are attached.

The Abstract and Summary of the Invention emphasize the importance of the large letters in the lower portion of the label. (Id. at col. 2, ln. 34-37.) In addition the background color is distinguished from the human readable characters in the Summary of the Invention. (Id. ln. 27-31.) The '816 patent explains the human readable code may be a number of letters or numbers and that it is not necessary to have only two letters or numbers adjacent to the bar code but never suggests the background color could be the human readable code. (Id., col. 3, ln. 32-42.)

Moreover, the claims distinguish the human readable code from the background color. Claims 2-4 and 8-10 distinguish "the human readable code" from the background color" which is printed "around said human readable code wherein said background color comprises a third code . . . ." (Id., col. 4, ln. 20-31.) Dependent Claims 3 and 9 state the human readable code is printed vertically along the longitudinal axis of the label, while dependent Claims 4 and 10 require that it be printed horizontally. (Id., col. 4.)

I find the specification itself, the best guide to the meaning of the term, dispositive. See Vitronics, 90 F.3d at 1582. The only way to construe the term "human readable code" that is consistent with the specification necessarily excludes a colored background. The specification is clear, the human-readable code is alpha-numeric and the colored background around the human readable code is a separate and distinct feature, indicated as a third code.

Even if I did not consider the specification itself dispositive, the file history is also consistent with a finding that the human readable code required by claims consists of the alpha-numeric characters, rather than the background color. The arguments presented to the Patent Office to distinguish the prior art, consistent with both the specification and the claims, were based upon the size of the alpha-numeric, referring repeatedly to the size of the characters on the label rather than the background color. (Substitute Br. Supp. Mot. Summ. J., Ex. B, Response at P. 6-7.) I therefore conclude, based on the intrinsic evidence that, properly construed, "symbols of said human readable code" does not include background color. I next determine whether a genuine issue exists as to whether the Dataware FAST-SCAN TM label infringes the asserted claim as properly construed. See Markman, 52 F.3d at 976.

B. "Arranged Symmetrically" and "At Least Seven Layers Arranged Symmetrically"

1. The Parties' Proposed Constructions
Cryovac argues that the claim term "arranged symmetrically" should be construed as part of the phrase "at least seven layers arranged symmetrically" to mean:

at least the seven layers recited in subparagraphs (a), (b), (c) and (d) of claim 11 arranged such that one layer (b), one layer (c) and one layer (d) are in the same order on each of the opposite sides of the core layer (a), for example c/d/b/a/b/d/c. This claim phrase limits the arrangement of the layers. It does not limit the thickness of the layers. Nor does it limit the amounts of recited components or additives that may be included in the layers.

(D.I. 203 at 24.) In support of their proposed construction, Cryovac argues that the context, grammar, specification, and prosecution history of claim 11 show that only the arrangement of the layers must be symmetrical and that there is no limitation requiring symmetry in the thickness or chemical composition of the layers. (D.I. 203 at 25.) Specifically, Cryovac contends that "symmetrically" modifies "arranged", which shows only that the layers must be in symmetric order, not that "the layers are themselves symmetric." (Id.) Additionally, Cryovac argues that the specification of the '419 patent, which has language referring to the thickness of "each" layer, shows that the thickness of the layers can vary individually. (Id. at 27.) Cryovac also asserts that Pechiney's proposed construction would exclude preferred embodiments (id. at 28), and that the prosecution history does not support the additional limitations Pechiney attempts to read into the claim (id. at 30).

Pechiney, on the other hand, argues that absolute symmetry is required in the thickness of the layers and their chemical composition. Pechiney asserts that the intrinsic evidence in the patent and the ordinary meaning of the terms support its reading of the claim. (D.I. 204 at 7-8.) Pechiney proposes that "arranged symmetrically" should be construed to mean:

Putting the layers in a desired symmetrical order when the film is viewed in cross-section, that is, putting the layers in an order so that the geometrical center line of the core layer is in the geometrical center line of the film and there is correspondence in the size (thickness) and composition of layers being mirror images of each other with the same thickness and the same chemical composition.

(D.I. 204 at 7.) Pechiney contends that its construction is consistent with the specification of the '419 patent, as the specification discusses a "symmetrical seven layer structure," but never defines the term "arranged symmetrically," and gives no example in which corresponding layers had different thicknesses. (Id. at 10-13.) Pechiney further argues that because during prosecution Cryovac distinguished claim 11 of the '419 patent from a prior art film that was "asymmetric", that claim 11 only covers films that are symmetrical in arrangement, layer thickness, and layer composition. (Id. at 13-17.) Finally, Pechiney argues that in looking at the whole claim, Cryovac's construction renders the "arranged symmetrically" limitation superfluous. (Id. at 18-20.) Thus, the dispute between the parties hinges on whether the claim term "arranged symmetrically" refers simply to the order of the layers, as Cryovac asserts, or whether that term requires absolute geometrical symmetry, as Pechiney contends.

2. The Court's Construction

The plain language of claim 11 and the prosecution history of the '419 patent support Cryovac's assertion that the term "arranged symmetrically" requires only symmetrical arrangement of the layers in the film, but not precise identity in the thickness or chemical composition of those layers. First, looking simply at the plain language and grammar of claim 11 of the '419 patent, what is claimed is a film "having at least seven layers arranged symmetrically." See U.S. Patent No. 4,755,419 at col. 9, Ins. 67-68. The word "symmetrically" modifies the word "arranged," and thus requires only that the layers should be symmetrical in their arrangement. Nothing about this language requires or even suggests that corresponding layers must be precisely identical in thickness or chemical composition, having geometric symmetry around a center line.

Furthermore, the prosecution history of the '419 patent favors this construction of the term "arranged symmetrically". To support its argument that there must be absolute symmetry in the thickness and chemical composition of the layers of the film, Pechiney attempts to rely on the fact that, during the prosecution of the '419 patent, Cryovac added the "arranged symmetrically" claim limitation to overcome a prior art rejection. (D.I. 204 at 16.) Indeed, Cryovac added this limitation to overcome an obviousness rejection over U.S. Patent No. 4,284,674 to Sheptak ("Sheptak") in view of U.S. Patent No. 4,532,189 to Mueller ("Mueller"). (D.I. 249, Ex. 3 at CR056-000155.) Sheptak, however, disclosed an eight layer film, with five layers that were symmetrically arranged and an additional three layers added to one side of the five layer film, making
the overall structure asymmetric. (D.I. 249, Ex. 6 (showing a film orientation of c/b/a/b/c/d/e/f).) Mueller disclosed three
and five layer films that appear to have a symmetrical arrangement, although that symmetry is not explicitly claimed. (D.I.
216, Ex. 12.)

Cryovac argued during prosecution of the '419 patent that Sheptak disclosed an asymmetrical film and that, as a result,
adding the outer layers of the film disclosed in Mueller would still give a structure that was asymmetrical. (D.I. 249, Ex. 3 at
CR056-000155.) Cryovac asserted that the film disclosed in the '419 patent had, by contrast, "at least seven layers [that
were] ... symmetrically arranged." (Id.) Cryovac claims that through this amendment it was simply distinguishing the prior
art by pointing out that the three additional layers added to the Sheptak film's symmetrical layers made that whole film
asymmetrical in arrangement, and that such an arrangement would remain asymmetrical even with the addition of the outer
layers from Mueller. (D.I. 248 at 29-31.) Nothing about this amendment shows, as Pechiney urges, that Cryovac was
asserting with the addition of this limitation that its claimed film had perfect symmetry in thickness and chemical
composition of the layers of the film. Accordingly, the prosecution history supports a construction of the term "arranged
symmetrically" that does not require precise identity in the thickness and chemical composition of the layers.

Finally, Pechiney urges that if Cryovac's proposed construction is adopted, the "arranged symmetrically" limitation would
be superfluous, as the body of the claim describing layers (a), (b), (c), and (d) teaches a film that is arranged symmetrically
under Cryovac's definition. However, although the body of the claim does teach that layers (b), (c), and (d) must be put in a
symmetrical order, nothing in the body of the claim prevents the addition of layers on one side of the (a) layer. Therefore,
without the limitation that the film must be "arranged symmetrically," an additional layer could be added on one side of the
(a) layer, making the film have a structure of c/d/b/a/b/d/c. Thus, "arranged symmetrically" is not superfluous as I have
construed it.

Having determined that precise identity in the thickness and chemical composition of the layers is not required by the term
"arranged symmetrically," there still remains the question of just how much alike the corresponding layers must be. The
claim language itself provides the answer to that question. Claim 11 of the '419 patent describes the composition of each of
the layers of the film. ('419 patent at col. 10, Ins. 1-9.) For example, (b) layers must each comprise a polyamide, and (c)
layers must each comprise a "polymeric material or blend of polymeric materials." (Id. at col. 10, Ins. 3-6.) Thus, the
chemical composition of the layers of the film claimed in claim 11 of the '419 patent is limited only by the definitions of the
layers themselves, as stated in the claim, and not by the claim term "arranged symmetrically."

Accordingly, I construe "arranged symmetrically" to mean "putting the layers in a desired symmetrical order when the film
is viewed in cross-section, so that the layers are in the same order on each side of the core of the film, for example
c/d/b/a/b/d/c. This claim phrase limits only the arrangement of the layers, and does not require precise identity in the
thickness of the layers or the amounts of recited components or additives that may be included in the layers." 5

--- Footnotes ---

5 Cryovac has urged that I construe the phrase "at least seven layers arranged symmetrically" rather than simply "arranged
symmetrically." Its proposed construction encompasses limitations set forth not only in that phrase, but also in other parts
of the claim. Because the limitations that Cryovac attempts to import into the construction of "at least seven layers arranged
symmetrically" are in other parts of the claim, I decline to import them into the construction of this term. Additionally,
because the meaning of "at least seven layers" is clear, I have construed only the phrase "arranged symmetrically."

</thead>
<tbody>
<tr>
<td>&quot;a syringe mounting for attachment to a syringe to position a syringe relative to said injector to permit said plunger drive ram to engage and move a plunger into or out of said syringe&quot;</td>
<td>a syringe mounting for attachment to a syringe to position a syringe relative to said injector head to allow said plunger drive ram to engage and move a plunger from outside to inside (to enter) or inside to outside (exit) of said syringe</td>
<td>a syringe mounting that attaches to a syringe, so that the syringe is positioned to allow the plunger drive ram to engage and move the plunger toward or away from a discharge tip of the syringe</td>
</tr>
</tbody>
</table>

The parties dispute whether this claim limitation is subject to 35 U.S.C. § 112 P 6 and whether the plunger must be capable of entirely exiting the syringe. E-Z-EM argues that "syringe mounting" lacks sufficient structure and is therefore a means-plus-function term. E-Z-EM also argues that the syringe mounting must permit the plunger to completely enter and exit the syringe. The dispute regarding a plunger is the subject of a pending motion for summary judgment.

a. "syringe mounting"

As a preliminary matter, the Federal Circuit has held that "the absence of [the word "means"] creates a rebuttable presumption that section 112, paragraph 6, does not apply." Phillips v. AWH Corp., 415 F.3d 1303, 1311 (Fed. Cir. 2005) (citing Personalized Media Commc'ns, LLC v. Int'l Trade Comm'n, 161 F.3d 696, 703-04 (Fed. Cir. 1998). E-Z-EM argues that "syringe mounting" connotes no structure and the '710 patent never uses or defines the term. E-Z-EM relies on testimony that one inventor had "trouble understanding what [syringe mounting] means" as evidence that it has no reasonably well understood meaning in the art. E-Z-EM Brief at 29.

Mallinckrodt argues that "syringe mounting" is used in common parlance and recites sufficient structure, citing to the Federal Circuit for the proposition that "it is sufficient if the claim term is used in common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the term identifies structures by their function." Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1359-60 (Fed. Cir. 2004). To support its contention that "syringe mounting" is used in common parlance, Mallinckrodt relies upon the testimony of E-Z-EM's expert, Alois Langer, about an unrelated patent application relating to powered syringes:

Q: Do you agree with the statement as set forth in [U.S. Patent Pub. No. 2007/0088270 P 2], "a typical power injector comprises an injector head having a syringe mount and a drive ram"?

A: It sounds like a reasonable statement.

Mallinckrodt Brief, Ex. 11 at 83:5-9. Mr. Langer further testified that a syringe mounting, "in the context of this patent, [is] some sort of mechanism that's used to attach a syringe to the injector." Id. at 32:9-13. To further buttress its argument that "syringe mounting" is used in common parlance, Mallinckrodt cites to a statement from the PTO during reexamination of the '710 patent that a "syringe mounting" was a "barrel clamp." Mallinckrodt Brief, Ex. 24, at 4.

The Court is of the opinion that E-Z-EM has not overcome the presumption that "syringe mounting" is not a phrase to which 35 U.S.C. § 112 P 6. "Syringe mounting" is not a term for which "one of skill in the art would have no recourse but to turn to the [patent's] specification to derive a structural connotation." Welker Bearing Co. v. PHD, Inc., 550 F.3d 1090, 1096 (Fed. Cir. 2008). A "mounting" is something that holds an object in place, and a "syringe mounting" is something that would
hold a syringe in place. Because a syringe is tube-shaped, "syringe mounting" connotes a structure that would hold a tube in place. Syringe mounting is therefore not a means-plus-function term.

b. "into or out of said syringe"

E-Z-EM argues that the plain meaning of "into" and "out of" necessitates the construction that the plunger is capable of entering and exiting the syringe. E-Z-EM applies the doctrine of claim differentiation to now-cancelled claims that recite "to permit said plunger drive ram to engage and move a plunger within said syringe." E-Z-EM Brief, at 33. According to the argument, the inventors knew how to draft a claim for a plunger that need not exit the syringe, but chose not to use those words in the asserted claim. E-Z-EM also relies upon the specification and claim preamble's use of "into" (e.g., "injecting fluids from a syringe into an animal subject") as showing that "into" means specifically "to enter." E-Z-EM Brief, at 34.

E-Z-EM glosses over those parts of the specification that use "into" and "out of" as directional terms. The specification explains that the plunger moves "toward and away from a discharge tip 40 of the syringe," but never mentions exiting the syringe. '710 patent, 6:20-23. The specification also recites that the plunger drive ram "move[s] forward, i.e., outward from the power head housing . . . [or] backward, i.e., into the power head housing." Id. at 10:56-63.

E-Z-EM's reliance on semantics does not give the Court a reason why, in the context of the claims, the plunger must be capable of completely exiting the syringe. The Court construes the limitation to mean, "a syringe mounting that attaches to a syringe, so that the syringe is positioned to allow the plunger drive ram to engage and move the plunger toward or away from a discharge tip of the syringe."

--- Footnotes ---

4 This construction also applies to the term "system" in the '987 and '505 Patents.

The court shall apply the ordinary definition of the term "system." The term "system" shall be construed to mean "an assemblage or combination of things or parts forming a unitary whole[.]

--- Footnotes ---

5) the term "tab holder" means "a structure designed to hold a tab;"

A. Table or Tables

The terms "table" or "tables" are recited four times in Claim 1 of the '270 patent, and each time the term is modified by "side grate" or "side." Plaintiff proposes that the term "table" be construed as "a flat unobstructed horizontal surface positioned at a height to be used for eating meals, operating cooking appliances and/or storage." Defendant proposes that the term be construed as "a substantially horizontal surface capable of supporting objects."

The portable modular field kitchen is first described in the background of the invention section of the '270 patent as a main work surface located at standard countertop height and "a pair of side tables located at standard table height for accommodating the serving of meals and the support of cooking equipment . . . ." (Col. 2, ll. 38-42.) However, under the "brief description of the drawings" section of the '270 patent, the side tables are referred to as "a pair of side shelves." (Col. 3, ll. 38-54.) This description distinguishes the side tables from the center food preparation work surface. (Id.) The specification describes the side grate table as "fashioned from steel in the same manner as the lower grate shelf." (Col. 7, ll. 34-38.) Thus, there is an inconsistency in that the tables are first described as "side shelves" and then distinguished from shelves in the specification identifying "table" and "shelves" as two separate features. The specification further identifies the side tables as "typically utilized for serving meals since the side grate tables 214 and 216 are positioned at table height, i.e., 28" above ground level." (Col. 8, ll. 13-16.) See also Column 9, lines 32-35 (the side grate tables are "positioned at 28" above ground level to facilitate eating meals"). The tables can be utilized for storage of kitchen articles, cookware, packaged food items, and other articles useful in a kitchen. (Col. 8, ll. 20-23.) In contrast, the center work surface is "positioned at standard countertop height of 36" above ground level to facilitate food preparation." (Col. 9, ll. 30-32.)

The claim language distinguishes a "horizontal work surface" from the pair of "side grate tables." (Col. 9, ll. 50-67.) The claim language further distinguishes the work surface and side tables from a "lower grate shelf." (Id.) These embodiments, according to the claim language, are three separate features: a work surface, a side grate table, and a lower shelf. If the patentee intended that the side tables be defined as shelves, the claim would have so stated. The specification of the patent further teaches that the side tables are typically the height for eating meals. Although the description of the drawings describes the side tables as side shelves, see Column 3, lines 43, 48, 52, the patent specification more-than-once describes the side tables as tables typically used for serving and eating meals and for storing kitchen articles. (Col. 18, ll 14-23; Col. 9, ll. 32-37.)

The claim must be read in view of the specification. See Phillips, 415 F.3d at 1315. Citing id. at 1323, Defendant warns against importing limitations from the specification into the claim. The purpose of the specification is to "teach and enable those of skill in the art to make and use the invention and to provide a best mode for doing so." Id. One of the best ways to teach the use of the invention is by providing examples of "how to practice the invention in a particular case." Id. Reading the specification in that context often makes it clear whether the patentee is setting out specific examples of the invention to accomplish those goals or whether the patentee intends that the claim and embodiments in the specification be coextensive. Id. Because of the distinctions set out in the claim between a horizontal work surface, side tables, and lower grate shelves in conjunction with the teachings in the specification, the Court finds that Plaintiff's construction of the term "table" to be accurate with some alteration. 2 Defendant's construction is over-broad and does not take the language of the specification into consideration.
2 Plaintiff includes the term "unobstructed" in its construction of "table." There is no support for or against that limitation. Defendant cites references to hooks, brackets, and suspended cooking articles as examples of obstructions. (Col. 9, ll. 16-22; Col. 8, ll. 50-52; Col. 3, ll. 15-17.) However, all of these cites refer to the area above the horizontal work surface and not to the side grate tables.

For the foregoing reasons, the Court construes the term "table" and/or "tables" as follows:

A horizontal surface positioned at a height typically used for serving or eating meals but may be used for the storage of items useful in a kitchen.

IV. "Tack Modifier"

Plaintiff argues that the term "tack modifier," as used in its patents, should be construed so as to include antioxidants when used in an amount greater than .03 percent of the total weight of the final product. To support this construction, Plaintiff uses several steps, based on intrinsic evidence. First, Plaintiff asserts that the antioxidants used in its product have two functions: a primary function of preventing degradation, and secondary function of modifying tack. Next, Plaintiff points to language in the '450 patent stating that "the use of excess antioxidants reduces or eliminates tack." Plaintiff then notes that the '450 patent specification has fourteen examples of mixtures to make their product, three of which have "very minor amounts" of antioxidants. These minor amounts are roughly .03 percent of the total weight of the final product. Plaintiff argues that these minor amounts must serve at least to prevent degradation, and therefore, that the amounts in "excess" as previously referred to, must be amounts over .03 percent.

Defendants argue that the term "tack modifier," as used in Plaintiff's patents, should include antioxidants only when used in an amount greater than three percent of the total weight of the product. Defendants note that the '450 patent states, "When a combination of antioxidants is used, each may comprise up to about three weight percent antioxidant. . . . When a combination of antioxidants is used, each may comprise up to about three weight percent antioxidant. . . . When a combination of antioxidants is used, each may comprise up to about three weight percent antioxidant. . . . When a combination of antioxidants is used, each may comprise up to about three weight percent antioxidant. . . . Additional antioxidants may be added for severe processing conditions involving excessive heat or long duration at a high temperature." Accordingly, Defendants argue that the patent teaches that up to about three weight percent of any one antioxidant is normal usage, and any more than this must be what the patent refers to as "excess."
Looking to the claim language itself, as well as the context in which that language is used, this Court finds that the proper construction of the term "tack modifier" should include an antioxidant only when that antioxidant is used in an amount greater than three percent of the total weight of the product. The '450 patent addresses a seeming upper threshold of antioxidant amounts when it states that "each [antioxidant] may comprise up to about three weight percent." Because the subsequent paragraph begins "the Applicant has unexpectedly found that the use of excess antioxidants reduces or eliminates tack," it follows that "excess" means amounts beyond those referred to in the upper threshold established in the preceding paragraph.

In comparison, Plaintiff's proposed construction is more attenuated, and illogical, as it essentially asks the Court to construe the terms in its patent to mean that any amount of antioxidants beyond "very minor amounts" must be "excess." Plaintiff seems to argue that because an amount of antioxidants equal to .03 percent of total product weight must serve the so-called primary antioxidant purpose of preventing degradation, this must somehow also be the bottom threshold at which the antioxidants begin to serve the alleged tack modifying function. However, the Court notes that there is no evidence within the patent terms that links prevention of degradation and tack modification in this manner. Therefore, acceptance of Plaintiff's proposed construction would require a substantial logical leap. Moreover, while Plaintiff argues that antioxidants are used in all of its products, nowhere does Plaintiff argue that its invention necessarily includes the excess antioxidant amounts necessary to serve a tack modifying function. To the contrary, the argument in Plaintiff's brief implies that at least some of its formulations exclude the amounts of antioxidants which would be necessary to modify tack. Accordingly, the Court will accept Defendants' proposed construction over Plaintiff's.

4. "tail"

The term "tail" first appears in the '086 patent claims in the phrase "constricting said tubular sock-like projectile body forward of said rear opening to close said rear opening thereby forming a tail." '086 patent, 5:9-11. Elsewhere in the claim, the unfilled tubular projectile body is described as having a "rear edge bounding a rear opening thereinto." '086 patent, 5:7.

Defendants' proposed construction of "tail" is the "tubular body portion of the projectile extending rearward from a constriction/delineation and including the rear edge through which shot is filled." Def. Op. Br. at 13. Plaintiff rejects the requirement that the tail be "extending" and include the "rear edge." Plaintiff's construction is that "a tail of a given length is formed dependent upon the location of where the projectile is constricted." Plaint. Br. at "Ex. F." Plaintiff is correct that nothing in the claim requires that the "tail" of the projectile be of a particular length. However, according to plaintiff, the tail also need not include the rear opening or rear edge, but rather may extend forward from the constriction to include the closed end of the tubular body.
Plaintiff's construction contradicts the ordinary meaning of "tail". A "tail" is ordinarily understood to be located at the "rear" or "end" of an object. The claim language "thereby forming a tail" indicates that the prior step in the preparation process, of constricting the projectile body, creates the tail. Thus, the constriction divides the projectile body into two sections, a front end and a rear end or "tail." The claim also requires that the constriction be located "forward" of the rear opening and that the constriction serves to close the rear opening, creating a divider between the opening through which the lead shot enters the projectile chamber and the location in which it is housed within the projectile. The rear opening is on one side of the constriction and the lead shot is on the other side. The claim later explains that the portion of the projectile that contains the "lead shot" is the "front end" of the projectile, employing the term "lead shot-filled closed front end." '086 patent, 5:13-14 (emphasis added). If the lead shot-filled section of the projectile is the "front end," it cannot also be the "tail." Rather, the "tail" must be the portion of the projectile body on the other side of the constriction, which includes the rear opening. Therefore, the "tail" is properly construed as the "portion of the projectile extending rearward from a constriction/delineation and including the rear opening, which is bounded by the rear edge."

GO BACK

4078

3. "tail portion"

Defendants' proposed construction of "tail portion" is "the tubular body portion of the projectile extending rearward from a constriction/delineation and including the rear edge through which shot is filled that has been folded into an organized bulk of material having a substantially cylindrical shape narrower than the cylindrical shape of the front end portion." Def. Br. at 17.

Plaintiff agrees that the tail portion has a substantially cylindrical shape and agrees that it "has a smaller cross-sectional dimension than the flattened (i.e. blunt) front portion." Plaintiff also rejects defendants' argument that the tail portion must be folded. Plaintiff intentionally and expressly removed the "forming folds" limitation, contained in the '562 patent, from the '133 patent. Plaintiff is correct that nothing in the claim language indicates that the tail must first be folded, as discussed in Part 6, supra. "Tail portion" is therefore construed to mean "the rear end portion of the projectile extending rearward from the lead shot-filled body compartment having a substantially cylindrical shape narrower than the cylindrical shape of the front end portion."

GO BACK

4079

Also at issue is claim language found in, e.g., claim 1:

A balloon for a medical device, the balloon comprising:

a length of tubing made of Nylon 12, said length of tubing have been formed into the balloon during a balloon forming procedure including inflating at least a section thereof with a pressurized fluid in order to radially expand said length of tubing to at least double its outer diameter;

said balloon has a non-distended working profile having a predetermined size to which the balloon inflates without significant stretching thereof, and said balloon has an expansion profile having a maximum inflated size to which the balloon stretches without bursting during use, said maximum inflated size being greater than said predetermined size of the non-distended working profile; and

said expansion profile of the balloon had been tailored whereby said balloon has a maximum inflated size selected from a range of maximum inflated sizes that are a function of balloon processing conditions.
1. "Tailored"

Cordis contends that the claim limitation requiring "tailorability" means nothing more than "to fashion or adapt to a particular taste, purpose, need, etc." (D.I. 49, Ex. 9 at 1361) Cordis maintains that because ACS supplies balloons of different sizes for different needs, the tailoring limitation is met.

The court disagrees on the record presented. In introducing the concept of "tailoring," the specification describes the invention as including "utilizing a tailorable material such as a nylon material or a polyamide material that is formed into a balloon by appropriate axial elongation, radial expansion and heat treatment procedures." (‘612 patent, col. 3, lns. 36-40) The specification goes on to state that "tailorability that is achieved according to this invention is a function of the particular heat setting conditions." (‘612 patent, col. 6, lns. 40-2) Consistent with the above, the specification provides that materials according to this invention should be able to be tailored during balloon formation to possess the ability to be stretched a generally predetermined percentage beyond its non-distended or working diameter, the amount of this percentage depending upon conditions under which the parison was processed into the balloon.

(‘612 patent, col. 11, lns. 60-66) Finally, the specification explains that "balloon expansion tailorability is a function of heat setting conditions and of hoop expansion ratio for balloon materials according to the present invention." (‘612 patent, col. 13, lns. 1-4) Illustrating this principle is

Figure 5 [which] gives four distention plots, tested at 37 [degrees] C for nylon balloons that are substantially identical except they were subjected to different heat set temperatures. In each case, the balloon was subjected to a 2 minute heat/cool cycle, with cooling being to room temperature. Each balloon was subsequently subjected to ethylene oxide sterilization. Curve F was subjected to a heat set temperature of 120 [degrees] C., curve G was at 130 [degrees] C., curve H was at 140 [degrees] C., and Curve I was at 150 [degrees] C. It will be noted that the curves illustrate different distention properties and the type of tailoring thus achieved.

(‘612 patent, col. 13, lns. 27-37)

--- Footnotes ---

1 As is generally the case with preliminary injunction proceedings, matters of claim construction and determinations of infringement and validity are preliminary and subject to change after discovery and trial.

--- End Footnotes ---

The claim language in dispute is consistent with the quoted passages from the specification, that is, that the "expansion profile 2 of the balloon has been tailored" so that the "maximum inflated size" of a balloon is "selected from a range of maximum inflated sizes that are a function of balloon processing conditions." (‘612 patent, claim 1 at col. 14, lns. 62-66) (emphasis added). In other words, "tailoring" according to the patent is more than making different balloons for different needs. It involves the use of varying balloon processing conditions to vary a balloon's expansion profile. To hold otherwise would be to negate the significance of this aspect of the invention.

--- Footnotes ---

2 The word "tailored" in claim 1 modifies the phrase "expansion profile," not the word "balloon." The "expansion profile" is the "maximum inflated size to which the balloon stretches without bursting during use. . . ." (‘612 patent, claim 1 at col. 14, lns. 57-9)

--- End Footnotes ---

GO BACK
5. "Tape:" 7 "Long, flexible strip of material." The parties generally agree with this construction, disputing only plaintiffs' proposal to additionally include the limiting phrase "substantially flat." Claim 3 of the '999 patent recites, "[t]he unshielded twisted pair communications cable as claimed in claim 1, wherein prior to cabling, the configurable tape separator comprises a substantially flat tape." (emphasis added) The presence of the additional limitation "substantially flat" in dependent claim 3 gives rise to a presumption that the limitation is not likewise present in independent claim 1. See Phillips, 415 F.3d at 1314-15.

7 '999 patent.

Plaintiff contends that claims 1 and 31 cover a valve head that is of uniform thickness in the outer portions of the valve head, so long as the exterior and interior surfaces converge toward the center to provide a valve head of tapered construction that is thinner at the center portion touching the orifice than at the outer portions. It points out, quite correctly, that the portions of the claims referring to radii do not require the radii to be non-concentric, which would necessarily lead to a continuous thinning (or thickening) of the outer portions. Radii of differing lengths which are concentric would result in walls of continuing equal thickness, the thickness depending upon the relative lengths of the radii. The disagreement between the parties relates to the subsequent language further defining the relationship of the radii:

such that said exterior and interior surfaces converge toward the central area of said head portion to provide a tapered construction with reduced thickness adjoining said orifice.

Those surfaces are the surfaces of at least the outer portion of the valve head. The central portion need not have converging curved surfaces and, indeed, in the figures set forth in the specifications the interior surface of the central area is generally shown as flat, thus resulting in a progressive but not uniform thinning adjoining the orifice at the center.

According to the plaintiff, "tapered" can mean inclined or angled and, in any event, does not require continuous thinning. "Such that" refers to the characteristics of the valve itself, namely that it is thinner in the center. "Converge" is a directional term; both surfaces can converge toward the center at the same angle. Plaintiff contends that the measurements of one embodiment described in the specifications (col. 10, lines 1-20), modified to correct an obvious typographical error, shows outer portions of uniform thickness. That is in accord with an earlier construction of the inventors (not part of the prosecution history) that demonstrated that outer portions of uniform thickness worked well, so long as there was a thinning adjoining the orifice.

We think plaintiff distorts the plain language. The quoted language above qualifies the claims as it relates to the radii. The valve head has outer portions, a central area and an orifice, as plainly appears in the patent drawings and as conceded by plaintiff in its fig. 2 on page 2 of its initial brief. The radii for the surfaces of the outer portions cause curved surfaces that converge toward the central area (which is different from the orifice) to provide a tapered construction prior to the central area, which results in a reduced thickness adjoining the orifice whether or not there is thinning in the central area. "Tapered" can, perhaps, sometimes be construed as inclined or angled, but here it cannot be so construed when it is used in conjunction with "converge." "Converge," according to Webster's Third New International Dictionary, means "to tend toward one point: approach nearer together … move toward a single point: come together …. In that context "tapered" has to mean what defendant contends: "becoming continuously narrower or more slender in one direction." Two surfaces approaching each other, such as a wedge.

Indeed, every figure in the patent drawings that depicts the outer portions shows continuous thinning of the outer portions.
We do not think the plain claim language can be recast because of a described embodiment which, even according to plaintiff, contains an erroneous measurement which would require the public to correct the error and then to draft the figure to understand what it discloses, and which, according to defendants (and we think correctly), would still result in a thinning outer portion. And, obviously, extrinsic evidence of what an inventor learned from his experimentation and what he thought he could claim, none of which is disclosed in the patent, is not entitled to consideration. Again, the public is entitled to rely upon the public record of a patent in determining the scope of the patent's claims.

Plaintiff correctly points out that claim 47 is an independent claim requiring its own construction. Defendants did not originally construe claim 47 and did not believe it necessary to do so because of a footnote to plaintiff's response to defendants' status report of December 23, 2002:

<1>Although this is neither the time nor the place to brief the substance of the claim construction, Plaintiff notes that while claim 1 of U.S. Patent No. 5,439,143 (which is attached to the Complaint) does recite that at least the outer portions be curved, it does not require that any particular portion of the valve head taper. In contrast, claim 47 of the '143 Patent is specifically directed at the construction shown in the drawings, and that claim does require an outer taper. See '143 Patent, col. 21, 11.22-24 ("and a generally inclined outer portion which tapers inwardly"). But this same language, and the limitation it conveys, is absent from claim 1.

Plaintiff has now backed away from the concession, but to no avail. Claim 47 does describe a different geometry. The surfaces of the outer portions are not defined by radii, at least not with respect to the interior surface. That surface can be, for example, a straight line which is, as stated in the claim, inclined (the patentee had no difficulty in using the word "inclined" when it meant inclined). That tells us little about the relationship between the exterior surfaces and the interior surfaces of the outer portions. But claim 47 goes on to include the same dependent clause found in claims 1 and 31: "such that said exterior and interior surface converge toward the central area of said head portion to provide a tapered construction with reduced thickness adjoining said orifice." We construe it in like manner as in claims 1 and 31. That conclusion is reinforced by the further description of "a generally inclined outer portion which tapers inwardly toward said circular center area ...." Again, we construe taper to mean an outer portion which becomes continuously narrower.

3. Tapered Implant

The parties' proposed constructions are as follows:

<table>
<thead>
<tr>
<th>Plaintiffs</th>
<th>Defendant</th>
</tr>
</thead>
<tbody>
<tr>
<td>An implant that gradually diminishes in diameter towards one end.</td>
<td>An implant including a frustoconically tapered portion.</td>
</tr>
</tbody>
</table>

The Court finds that Plaintiffs' proposed construction is appropriate because (1) the claim language describes a method for installing a tapered implant, which tapers from the proximal end to the distal end (Swaroop Decl. Ex. 1, col. 6, ll. 32-44), (2) the specification describes the implant as diminishing in diameter (Swaroop Decl. Ex. 1, col. 3-4), and (3) extrinsic evidence, such as dental dictionaries and general dictionaries, also support construing a "tapered implant" as an implant diminishing in diameter towards one end (Pl's Ex. 3 (Glossary) at 159; Ex. 12 (Webster's) at 2339).

The Court declines to adopt Defendant's proposed construction because it does not give effect to all terms in the claim and is incomplete. First, courts generally construe claim terms so as to give effect to all terms in a claim. Bicon, Inc. v. Straumann Co., 441 F.3d 945, 950 (Fed. Cir. 2006). Here, the claim explains that the tapered implant has a "cylindrical portion" and a "frustoconically tapered portion." (Swaroop Decl. Ex. 1, col. 6, ll. 32-44.) By defining "tapered implant" as including a "frustoconically tapered portion," Defendant's proposed construction does not give effect to the term "frustoconically tapered portion" in the claim. If the Court adopted Defendant's proposed construction, there would be no need for the claim to state that the tapered implant includes a "frustoconically tapered portion." Second, Defendant's proposed construction is incomplete because it does not describe the implant as diminishing in diameter, which is clearly described in the language of the claim. (Swaroop Decl. Ex. 1, col. 6, ll. 32-44.)

- 4734 -
In light of the foregoing, the Court adopts the following construction: An implant that gradually diminishes in diameter towards one end.

4083

2. A pair of spaced guides tapering in an outwardly direction

I conclude that the term "a pair of spaced guides tapering in an outwardly direction" as used in claim 10 of the '530 patent means two spaced guides, each tapering in a direction away from the centerline of the U-shaped channel on which it is located. The parties dispute whether both spaced guides need to taper outwardly. Plaintiff contends that they don't and defendant contends that they do. Defendant has the more persuasive position.

Nothing in the claim language itself allows the inference that the language "tapering in an outwardly direction" refers to only one of the pair of spaced guides. If the patentee intended such a meaning, he should have claimed "a pair of spaced guides at least one of which tapers in an outwardly direction." The most reasonable construction from reading the claim language is that both guides taper in an outwardly direction. This reading has further support in the specification, which discusses "a pair of spaced guides 90, each guide tapering in an outwardly direction," '530 pat., col. 5, Ins. 1-2, and the illustrations of the invention:

[SEE FIGURE IN ORIGINAL]

Plaintiff contends that the prosecution history of the '530 patent supports its construction. However, nothing in the prosecution history changes the claim language. Plaintiff notes that an earlier version of the '530 patent contained a dependent claim 12 that stated:

12. The snow plow assembly of claim 6 wherein the alignment means includes a pair of spaced guides,

each of the guides tapering in an outwardly direction.

Olejniczak Decl., dkt. # 17, exh. B, at DD 000143. Eventually claim 12 was removed from the patent, but the language in claim 12 was reworked into what is now independent claim 10, which no longer contains the "each of the guides" language. It is important to note that the patentee was not told to change claim 12 for validity reasons.

Contrary to plaintiff's argument, removal of the "each of the guides" language does not support the conclusion that the "tapering in an outwardly direction" was intended to apply to at least one of a pair of spaced guides. A more reasonable view of the removal of the "each of the guides" language is that the phrase was removed because it was superfluous and unnecessary. In creating independent claim 10, the "each of the guides" language would not have added anything but extra words because the phrase "a pair of spaced guides tapering in an outwardly direction" covered the same invention without the extra phrase.

4084

(1) The term "target material" in claims one, two, five through twelve and fourteen through sixteen. Defendants submit that "target material" simply means the specimen or object that is imaged by the laser scanning microscope. Plaintiffs argue the term means a specimen that has an ultraviolet (UV) excitible fluorophore. In support of Defendants' position, their expert, Dr. Ian Walmsley, explained that the patent itself states that the target material is the substance that will be "imaged." 2 613 Patent 9:64. 3 Dr. Walmsley also testified that the specification treats "target" and "specimen" synonymously. 613 Patent 4:39. Finally, in the prosecution history, target material is explained as something that "includes a fluorescent material that is responsive to short wavelength light." Prosecution History, Defendants' Markman Ex. 5 at 117 (hereinafter "Prosecution History"). Notably, this description does not require the definition that target material be excited in the UV range.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
Dr. Walmsley is the Chair of Experimental Physics in the Department of Atomic and Laser Physics at the University of Oxford. He received his bachelor's degree in physics from the University of London and his doctorate in optics from the University of Rochester. He has taught, lectured and published extensively on the subject of optics. Walmsley Curriculum Vitae, Defendants' Markman Ex. 32. The Court recognized Dr. Walmsley as an expert in non-linear and ultrafast optics, atomic molecular physics and optical system design. Dr. Walmsley stated that a person of ordinary skill in the art would have a bachelor's degree in a technical field such as physics, optical electrical engineering or biophysics, plus one or two years of experience using lasers or imaging. Before testifying, Dr. Walmsley had reviewed the patent's claims and specification and the prior art. Tr. 154-157.

Throughout this opinion, where appropriate, the Court will cite to the 613 Patent in column:line format.

Plaintiffs' expert, Dr. Scott Fraser defined target material as "target material labeled with a UV responsive fluorescent dye." Tr. 436. Dr. Fraser agreed that the only difference between his understanding of "target material" and that of the Defendants' was that he urged the presence of a UV excitable dye, based on his understanding that the short wavelength range specified in the patent is synonymous with the UV range. Tr. 438. According to Dr. Fraser, all the dyes mentioned in the specification are UV excitable. Tr. 439. On cross examination, Dr. Fraser testified that the target material did not need to fluoresce for purposes of claim 7. Tr. 480-81. Yet, earlier in his testimony he had said the term should have the same definition wherever it appears in the patent. Tr. 442.

Dr. Fraser received his bachelor's degree with honors in physics from Harvey Mudd College and a Ph.D. with distinction in biophysics from Johns Hopkins University. He is a professor of biology and a director of the Biological Imaging Center at the California Institute of Technology. He has lectured and published extensively. The Court notes he is on the Board of Directors for Carl Zeiss, Inc. as an outside member and advises on the sales and service of products. Fraser Expert Report, Plaintiffs' Markman Ex. 52. The Court recognized Dr. Scott Fraser as an expert in the field of imaging technology, including laser scanning microscopy and the use of ultra fast lasers as they relate to that field. Tr. 406. Dr. Fraser's understanding of a person of ordinary skill in the art is "somebody that has a bachelor's level degree in biology or one of the physical sciences or engineering and that has one to two years of practical experience in microscopy or imaging science." Tr. 431-32.

The Court will not read an unsupported limitation into the term "target material." Comark Communications, 156 F.3d at 1186. In fact, contrary to Plaintiffs' assertion, the patent is clear that the target material can fluoresce in something other than the UV range. 613 Patent at 6:50 (describing fluorescence at 315 nanometers, in the ultraviolet region); 6:53 (describing fluorescence at 535 nanometers, in the visible light region). Accordingly, the Court interprets the term to mean: "The specimen or object that is imaged by the laser scanning microscope."
first and second occluding disks, each disk comprising a flexible, biologically compatible membrane capable of being collapsed for passage through a catheter and elastically returning to a predetermined shape for tautly holding a portion of the membrane against a septum.

'291 patent claim 1 (emphasis added).

The relevant language of claim 1 of the '281 patent covers a first member and a second member each comprising a self-expanding structure exhibiting a spring-like behavioural component for moving the member between a compressed orientation for passage through a medical instrument having an inner diameter and an expanded orientation having an enlarged diameter for tautly holding at least a portion of the closure device against a septum.

'281 patent claim 1 (emphasis added).

The two claims are largely parallel. Where the '291 patent has first and second "disks," the '281 patent has first and second "members"; where the '291 patent has "comprising a . . . membrane," the '281 patent has "comprising a . . . structure"; and where the '291 patent has "a portion of the membrane," the '281 patent has "at least a portion of the closure device." Both claims specify that something is "for tautly holding" something else ("a portion of the membrane" or "at least a portion of the closure device") against a septum.

In excerpting the relevant claim language in the amended JCCS, the parties decided to treat the phrase "tautly holding," minus the preposition "for," as if it modified "membrane" in the '291 patent and "member" in the '281 patent. Am. JCCS Sched. B at 8, 11. They did not explain how they reached this decision, and the Court finds it to be unsupportable. To begin with, omitting "for" is unjustifiable: A "steak for cooking" is not the same thing as a "steak cooking." The claim contains the prepositional phrase "for tautly holding," which is different from the phrase "tautly holding." The Court must construe the claim as it is written.

The prepositional phrase "for tautly holding" could function as either an adjective (by modifying some noun phrase) or as an adverb (by modifying some verb phrase). See Rodney Huddleston & Geoffrey K. Pullum, Cambridge Grammar of the English Language ("Cambridge Grammar") 612, 656 (2002); Randolph Quirk et al., A Comprehensive Grammar of the English Language 657 (1985). Thus, in the sentence "I own boots for walking," the prepositional phrase "for walking" modifies the immediately preceding noun "boots" and functions as an adjective. But in the sentence "I bought those boots for walking," the prepositional phrase "for walking" modifies "bought" and thus functions adverbially.

10 Modern grammarians use relatively unfamiliar terminology to describe how prepositional phrases relate to other parts of speech and to clauses. See Cambridge Grammar 646 (describing prepositions functioning as "complement," "adjunct," and "modifier"). The Court uses simpler terminology that is likely more familiar to readers who are not trained in linguistics.

In claim 1 of the '291 patent, the phrase "for tautly holding" could modify the noun "shape," which immediately precedes "for tautly holding." Although prepositional phrases that serve as adjectives generally modify the immediately preceding noun, "shape for tautly holding" is implausible, since the closure device's shape, as such, does nothing. More plausibly, "for tautly holding" is intended to modify either the activity of "being collapsed . . . and elastically returning," or the elastic property demonstrated by that activity. Thus, the relevant portion of claim 1 of the '291 patent could be paraphrased this way:

The device comprises two disks with elastic properties. By virtue of these elastic properties, the disks can be collapsed for passage through a catheter and will return to their predetermined shapes when they exit the catheter for deployment on the two sides of a septum. These elastic properties will cause part of the disks --when deployed in their expanded, predetermined shapes --to be held tautly against the septum.

In claim 1 of the '281 patent, the phrase "for tautly holding" could modify the immediately preceding noun "diameter." But "diameter for tautly holding" is as implausible as "shape for tautly holding," and for a similar reason: A "diameter," as such,
does not do anything: a diameter is just a measurement. But the other possible readings -- "orientation . . . for tautly holding," "behavioural component . . . for tautly holding," "member . . . for tautly holding -- are equally unsatisfactory. In short, claim 1 of the '281 patent is, from a syntactic standpoint, even more poorly formed than claim 1 of the '291 patent.

Yet the gist of claim 1 of the '281 patent, and of the "tautly holding" claim language, is clear enough. Claim 1 of the '281 patent, like claim 1 of the '291 patent, covers a spring-like structure that is compressed during delivery and then expands upon deployment. After the structure is expanded, its springiness causes it to be tautly held against the septum in which it is deployed. The Court need not parse the unparseable language of claim 1 to be able to construe the phrase "tautly holding" and to resolve the parties' dispute over that phrase.

The Court agrees with AGA that for a structure to be tautly held against a septum, the structure itself must be taut, and the structure must be held tightly against the septum. See Am. JCCS Sched. B. at 11; AGA Opening Br. at 25-26. Further, the Court agrees with the University that "taut" has its ordinary meaning in the '281 and '291 patents. Univ. Opening Br. at 25-26. That said, though, the Court finds that most -- though not all -- of AGA's proposed claim construction follows from the ordinary meaning of the word "taut."

The relevant definition of "taut" in Webster's Third is "tightly drawn: tensely stretched: not slack <<the flesh seemed smoothed back, even painfully [taut] --R.P. Warren> <<a piece of strong fabric about one yard square, kept [taut] by a wooden frame --H.W. Dowdesell>>." Webster's Third 2344. 11 As the second illustration in this definition shows, a central instance of something "taut" is a thin sheet under tension across its surface, such as a drum head. This meaning of "taut" fits naturally with the invention disclosed in the '281 and '291 patents -- an invention featuring disks (or "members") that spring into shape when they are deployed.

--- Footnotes ---

11 The relevant definition of "taut" in AHD Third is: "[p]ulled or drawn tight; not slack." AHD Third 1839. This is entirely consistent with the definition in Webster's Third, but is less informative.

--- End Footnotes ---

Indeed, the word "taut" is used repeatedly in the specification in its ordinary sense. In particular, the specification says that, in an embodiment in which membranes are attached to frames, the frames "hold the membranes tautly and in intimate contact with the outer surface of the septum." '291 patent col. 10:19-21. 12 The Court therefore construes "tautly holding" consistently with the specification and with the ordinary meaning of the word "taut," and illustrates the phrase's meaning for laypersons with the easily understood example of a drum head.

--- Footnotes ---

12 See also '291 patent col. 5:6-14 (describing a preferred embodiment in which a frame "around the periphery of the membrane" serves, "in its natural, non-deformed state, . . . to hold the membrane . . . taut. . . . Normally, the frames . . . of the device pull their respective membranes . . . into a taut, generally planar shape . . . ").

--- End Footnotes ---

The Court's construction of "tautly holding" differs from AGA's in only two material respects. First, in AGA's proposed constructions of the disputed terms (as the parties formulate those terms), AGA identifies the thing that is doing the holding as the "membrane" in the '291 patent and the "member" in the '281 patent. Am. JCCS Sched. B at 8, 11; AGA Opening Br. at 25-26. The University objects to this aspect of AGA's proposed construction. Univ. Opening Br. at 26-27. For the reasons already given, the Court does not find it either possible or necessary to identify precisely what holds the disks or members taut.

Second, under AGA's proposed claim construction, "all slack" must be removed from whatever is being held tautly. Am. JCCS Sched. B at 8, 11 (emphasis added). Although something "taut" necessarily has little or no slack, tautness is a question of degree. The '281 and '291 patents use the phrase "tautly holding," not "holding somewhat tautly" or "holding extremely tautly" or "holding absolutely tautly." But AGA's proposed construction would, in effect, transform "tautly holding" into
"holding absolutely tautly." Whether something is "held tautly" is a question of fact for the jury. Whether something is "held absolutely tautly" is a different question -- one that the disputed claim language does not raise.

3. Tear

The parties vigorously dispute the meaning of the word "tear" in the context of the '952 patent. SDP avers that "tear" means "the application of force to a material . . . in order to cause a division or separation between portions of the material; the result of tearing usually, but not always, leaves ragged edges on the portions of material that have been torn." Pls.' Br. in Supp. of Summ. J., at 17. See also Pls.' Reply at 17. Apparently, SDP believes that there is an ambiguity about the meaning of "tear" in the '952 patent that is created by the claim language, the specification and the prosecution history. Pls.' Reply at 12, 16. Therefore, SDP suggests that using expert testimony and the dictionary to define "tear" is appropriate and necessary. Pls.' Reply, at 16-17. SDP asserts that the WEBSTER'S DICTIONARY definition of tear would conform with and reconcile the ambiguity in the intrinsic evidence. Id. at 17. Thus, its proposed definition for tear, excluding its references to the device itself, is directly from WEBSTER'S DICTIONARY. The definition SDP proposes states in full:

Claims 26, 30, 33 and 38-40 of the '952 Patent use the terms "tear" or "tearing." You are instructed that these terms refer to the application of force to a material, such as the base of a needle plunger, in order to cause a division or separation between portions of the material. Tear implies a forcible, somewhat crude, pulling or wrenching away. The result of tearing usually . . . leaves ragged or irregular edges on the portions of material that have been torn.

Id.

In contrast, NMT contends that the proper definition for "tear" within the context of the '952 patent is "tearing a portion of the rupturable web or boot thereby forming a flap (a portion of the web or boot still attached to the remainder of the boot or web), but do[es] not include the complete separation of a button or breakable piece from the end of the plunger." Defs.' Br. in Opp'n, at 6-7. NMT avers that its definition is the only proper one when the word "tear" is defined with reference to the prosecution history. Id. at 7. According to NMT, the prosecution history reveals that a definition of "tear" that includes "to break" would be obvious in light of prior art in U.S. Patent No. 5,114,410 to Battle (the "Batlle patent") and U.S. Patent No. 4,994,034 to Botich et al. (the "Botich patent"). Id. at 9. The patent examiner had rejected the use of the word "rupture" in the '952 patent's predecessor applications because SDP had defined "rupture" as "to break." Accordingly, SDP changed "rupture" to "tear" in the patent to describe what happens to the rupturable web when it is contacted by the needle head with enough force. See id. In addition, NMT argues, SDP sought to distinguish the prior art during prosecution by explaining that "a portion" of the rupturable web is torn or ruptured during operation of its invention, but the discoid button at the end of the plunger in Battle is completely dislodged. Id. at 10 (citing Defs.' Exh. 7, App. No. '007, at 61, 66). Therefore, according to NMT, the definition of "tear" should include reference to leaving a portion of material behind. Further, NMT argues that the Court should construe the word "tear" without resort to extrinsic evidence, such as a dictionary or expert testimony, because the plain meaning of "tear" and the '952 patent prosecution history provide sufficient intrinsic evidence of the proper construction for the term. Id. at 11-13.

The Court finds merit in both parties' arguments. The Court will start with the plain meaning of the claim language. "Tear" is used in the disputed independent claims as follows:

26. A syringe comprising:

* * *

a rupturable web on said forward end of the plunger;

wherein a fluid can move from within said barrel through said needle as said plunger moves through said barrel to said deformable base, and when said rupturable web contacts said deformable base, continued movement of said plunger moves said deformable base toward said first end, said rear end of said needle thereby tearing said web . . . .
30. A process for retracting a needle upon completion of subcutaneous injection with a hypodermic syringe comprising the steps of:

forcing an end portion of said head to tear a base portion of said plunger; . . . .

38. A syringe apparatus comprising:

a rupturable web on an end of said plunger . . . ;

whereby when said plunger moves through said barrel toward said needle assembly, a fluid can be moved from said barrel through the hollow of said needle, and continued movement of said plunger moves said deformable base downwardly until such time as sufficient force is imparted to said rupturable web by said enlarged head of said needle to tear said rupturable web . . . .
A portion of boot 43 is illustrated as having been torn by the needle head in FIG. 2, with boot web 79 laying over in the front of plunger 7.

* * *

...Continued force causes further translation of base 11 and needle head 13 to tear web 79 of boot 43, positioning enlarged needle head 13 just inside hollow 41 of plunger 7...

Id. col. 5, ll. 42-44; id. col. 9, ll. 24-27. Again, these descriptions imply that a portion of the web material remains attached to the original portion of the material after the tearing or separating has occurred. In other words, only a portion is separated, not the whole.

The specification also uses the words "penetrate" and "puncturing" to describe the "tearing" process of the web. The specification reads: "Continued force causes the enlarged needle head to penetrate the web of the boot, positioning the enlarged needle head just inside a hollow portion of the plunger." Id. col. 3, ll. 2-5. Further:

To aid in the rupturing process of the web, tear groove 26 and tear groove 28, shown in figure 9B, are provided. The thickness of web 79 and the tear grooves are selected to withstand normal operating pressures within syringe 1, as shown in FIG. 1, but to allow relative ease in the puncturing of web 79 by enlarged needle head 13, shown in FIG. 6.

Id. col. 7, ll. 3-10. Similarly to the other passages describing the action of the needle head being forced against the rupturable web, these passages connote the parting or the separation of a material to allow something to pass through an opening created in it, but not the complete separation of the material from its points of attachment. In other words, penetrate and puncturing connote a "breaking through" or a "breach" of the web, but not a breaking apart completely.

Moreover, it is clear that "tear" should replace "penetrate," and "tearing" should replace "puncturing" in these passages without changing the scope of the claims. For that to hold true, the definition of "tear" should convey a separating of portions to create an opening, but not a complete separation of the material from its points of attachment. In other words, "tear" and its apparent synonyms in the '952 patent. Therefore, the specification apparently teaches that "tear" means "to separate a material into portions by force to create an opening therein, without a complete breaking away."

A definition of "tear" that excludes a complete "breaking away" is consistent with the prosecution history. As presented above at length, during prosecution of the '952 patent's predecessor applications, the inventors struggled to find a word to describe the action of the needle head through the rupturable web that was not rendered obvious by the prior art. See generally Defs.' Exh. 7, App. No. '007; id. App. No. '001. Initially, the applicants used the word "rupture" to describe the action of the needle against the rupturable web, which the patent examiner rejected stating: "Claim 13 is rejected under 35 U.S.C. § 102 (a or e) as being anticipated by Batlle." Id., App. No. '007, at 43. In response, the applicants offered the definition of "ruption" to the patent examiner along with an explanation of how the action in their device differed from the action described by the Batlle patent. Defs.' Exh. 7, App. No. '007, at 60-62. The applicants used a definition of "ruption" from WEBSTER'S DICTIONARY: "to part by violence: break, burst." Id. at 61. The patent examiner rejected the use of the word "ruption" with this definition because he found "to break" equivalent to the dislodging taught in the Batlle patent. See id. at 66. However, the patent examiner would accept the word "torn" or caused to "tear." See id.

The applicants subsequently amended their claims to read "torn" and caused to "tear," however, they introduced new claims using the word "penetrate" and the phrase "penetrates said base portion of the plunger by rupturing." Id. at 69-71; id. App. No. '001, at 79. The patent examiner allowed the amended claims that used "torn" and caused to "tear," but rejected the new claims using "penetrate." Id. App. No. '001, at 81-82. The examiner stated: "The broad recitation and meaning of "penetrate" and "rupture" is considered to be fully met by the breaking action disclosed by Batlle." Id. at 82. Clearly, the examiner would disallow any claims that purported to use a definition of what happened to the rupturable web that included "to break."

A brief review of the cited prior art, particularly the Battle patent, might be helpful. The Battle patent describes a syringe with a retractable needle. Batlle Patent, Abstract. Its only independent claim describes an opening on the end of a piston without further describing the type of opening or whether it is covered. Id. col. 5, ll. 15-16. The only dependent claim
describes a specific part that covers the opening in the end of the piston, "a discoidal button," that is fit into a groove on the inside of the hollow plunger. Id. col. 6, ll. 5-20. The "discoidal button is dislodged" from the groove when the needle is released into the barrel by the action of the end of the plunger against the part holding the needle, which in turn releases a spring that pushes the needle into the hollow of the plunger. See id. col. 6, ll. 16-20; id. col. 5, ll. 4-21. The force of the needle head, powered by the spring, dislodges the "discoidal button." See id. col. 5, ll. 11-13; id. col. 6, ll. 16-19. It is this dislodgment that the patent examiner found equivalent to a breaking and therefore readable on the claims of the '952 patent when "rupture" meant "to break."

The patent examiner found the use of a word that connoted "to break" objectionable because the prior art would render such an action obvious; therefore, the definition of "tear" must convey something other than a breaking away as suggested by the dislodging in Batlle. See Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution."). The applicants themselves tried to convey a difference in the very same passage in which they defined "rupture" to mean "break." They argued:

. . . During operation of the needle in Batlle, the button 14 is forced completely out of the groove 15 and forced back up into the piston.

The pertinent portion of Applicant's [sic] independent claim 13 claims "forcing an end portion of said needle to rupture a base portion of the plunger" (emphasis added). A pertinent part of the specification is amended herein states as follows:

As deformable base 11 moves forward, enlarged needle head 13 begins to protrude from base 11 and come into contact with web 79 of rupturable boot 43 on plunger 7. Continued force causes further translation of base 11 and enlarged needle head 13 to tear and penetrate web 79 of rupturable boot 43 . . . .

. . . As clearly illustrated in figures 2 and 19 through 23, a portion of the rupturable boot 43 is torn or ruptured in order for the needle to penetrate the rupturable boot 43.

Defs.' Exh. 7, App. No. '007, at 61 (emphasis in original). From this part of the inventors' argument, the difference between "dislodging" and "rupturing" seems to be the difference between "breaking away" and "tearing a portion." The inventors themselves argue that "a portion" of the rupturable web is torn such that the needle can penetrate it. Id. In other words, "tear" is the separation of a portion of a material from another portion such that an opening is created to allow the needle head to pass through it; but, it is not the complete breaking away of a part because that would be akin to the dislodging in Batlle and therefore obvious in light of the prior art.

In the analysis, although the Court agrees in large part with SDP's proffered definition for "tear," the definition must include the notion that a "breaking through" or a "breach" is acceptable, however, a "breaking away" is unacceptable. This is necessary in light of the prosecution history that indicates the patent examiner specifically found anything that conveyed "to break" the rupturable web readable on the claims of the '952 patent. In addition, such a limitation is necessary, in part, because the specification indicates that a portion of the web breaks away not the entire web. The court will construe claims terms, whenever feasible, to sustain their validity. See Wang Labs., Inc. v. America Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999); see also Southwall Tech., 54 F.3d at 1576.

In light of the plain meaning of the claim terms, the specification and the prosecution history, the Court finds that "tear" means "to separate a material into portions by force to create an opening therein, without a complete breaking away." The Court declines SDP's invitation to import the entire WEBSTER'S DICTIONARY definition that includes descriptions of edges because such description is unnecessary.

4087

Both the '015 and '167 patents claim "a pair of spaced apart tear impressions extending inwardly from the edge" of the container lid to the central portion of the lid. Both patent specifications provide that these tear impressions may be "molded, embossed or scored as a single continuous line into the surface of the lid . . . [or may] each be performed as a plurality of spaced apart, relatively short impressions." The '015 specification provides that the function of these tear impressions is "to
C. Tear Impressions

Dart raises a number of alleged differences between Dart's lids and the tear impressions claimed in claim 1 of the '015 patent. First, Dart argues that claim 1 requires that the tear impressions extend to the outer edge of the container and that the corresponding component in Dart's lids does not extend to the outer edge. Second, Dart submits that the term tear impressions only encompasses a pair of linear impressions on the surface of the container lid. Dart points out that the corresponding components of Dart's lids are not linear but rather comprise a series of corrugations with sawtooth shapes having wide outer ends and narrow inner ends. In addition, such corrugations, according to Dart, do not foster failure of the material along "predetermined lines" ('015 patent, col. 3, l. 9), but, instead, foster failure of the material anywhere within the trapezoidal region formed by the sawtooth corrugations. Further, the sawtooth corrugations are not impressions inasmuch as they extend perpendicular to the direction of the tear. In contrast, according to Dart, the impressions described in the '015 patent run along the surface of the container lid and extend along the direction of the tear.

Claim 1 of the '015 patent 5 claims "a pair of spaced apart tear impressions extending inwardly from the edge of the container lid." ('015 patent, col. 5, l. 22-23). Each tear impression terminates "at separate tear stop means." The tear...
impressions together with the tear stop means operate to define "a reclosable access strip having a self-forming hinge area." ( '015 patent, col. 5, l. 24-28). The entire subparagraph in claim 1 pertaining to tear impressions reads as follows:

a pair of spaced apart tear impressions extending inwardly from the edge of the container lid, each impression terminating at separate tear stop means therefor within said central portion thereof, said impressions and said tear stop means together defining a reclosable access strip having a self-forming hinge area affixing said access strip to said container lid.

('015 patent, col. 5, l. 21-29).

5 The remaining claims in the '015 patent are dependent on claim 1 or claim 4. Claim 4 is dependent on claim 1. Hence, all of the claims of the '015 patent include the claimed tear impressions.

The words "from the edge of the container lid" do not state from the outer edge of the container lid. Further, the words do not read or require that the tear impressions physically touch the edge of the container lid. The plain and ordinary meaning of such language to one skilled in the art does not, necessarily, exclude extending inwardly from the inner edge of the container lid. Nor does the language and the word "from" necessarily exclude a tear impression spaced a short distance from the edge of the container lid. The language also does not describe the tear impressions as linear, perpendicular, straight, wide, narrow, of varying widths or following a predetermined line. Rather, the language concerning tear impressions in claim 1, as read by one skilled in the art, demonstrates that tear impressions simply extend inwardly from the edge and terminate at a tear stop means. For further guidance, therefore, this court turns to the specification and the prosecution history.

The specification describes tear impressions in the following manner:

In accordance with the invention, container lid (10) comprises a pair of spaced apart tear impressions (22) which extend inwardly from edge (20) and each of which impressions (22) terminate in tear stop means (24) located within central portion (12). It is the role of tear impressions (22) to foster failure of the polymeric material of construction along the predetermined lines defined thereby. Accordingly, said impressions (22) may each be molded, embossed or scored as a single continuous line into the surface of lid (10) (as shown in FIG. 1) or may each be performed as a plurality of spaced apart, relatively short impressions (23) (as shown in FIG. 3).

('015 patent, col. 3, l. 3-14).

The drawings, figures 1 and 3, also depict the spaced apart tear impressions. The language describing the tear impressions in figures 1 and 3 show two embodiments. The language accompanying figure 1 discloses a single continuous line ( '015 patent, col. 3, l. 11-12) while the language describing figure 3 ( '015 patent, col. 3, l. 13-14) discloses a plurality of spaced apart, short impressions (23) (as shown in FIG. 3).

('015 patent, col. 3, l. 3-14).

Figure 1 pictures a single, continuous line. Although the specification does not expressly describe the continuous line as a straight line, the accompanying drawing illustrates a straight, uninterrupted line from the outer edge of the container to the tear stop means. Figure 3 mistakenly illustrates the "plurality of spaced apart, relatively short impressions" as a single, unbroken line ( '015 patent, fig. 3, 23) which, using the same language ( '167 patent, col. 3, l. 27-28), the '167 patent correctly illustrates as a series of dashed lines. ('167 patent, fig. 3, 20).

Thus, the specification discloses two forms of tear impressions, one being a single, continuous line and the other being a plurality of spaced apart, relatively short impressions. Although the specification cannot redefine the terms of claim 1 of the '015 patent, it nevertheless may serve as a useful guide or dictionary to elaborate upon the meaning of the terms. Thus, the term tear impressions in claim 1, as disclosed in the claim and further defined in the specification to one skilled in the art, may encompass a series of short, spaced apart impressions running along, but nevertheless molded into, the surface of the container lid. In describing the plurality of spaced apart, relatively short impressions, the specification does not describe these impressions as nonperpendicular or as forming or limited to a particular shape other than being short and/or fostering
the failure of the material along predetermined lines. 6

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

6 Ordinarily, "impressions" are formed by pressing or applying an external force to produce a mold or figure. (Docket Entry # 60, Ex. 13).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

In addition, the description accorded the plurality of spaced apart relatively short impressions leaves room for an interpretation of the impressions as having slight variations in width. Because a description in a specification does not define or delimit the claims to necessarily encompass only the description of the invention contained in the specification, the tear impressions claimed in the '015 patent may therefore reach and include a plurality of spaced apart impressions which have a slight degree of variation in width as interpreted by one skilled in the art. 7

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

7 This court limits this claim interpretation regarding width to the motion for partial summary judgment (Docket Entry # 5). Accordingly, this interpretation does not comprise part of the law of this case.

In the alternative, and assuming arguendo that the term tear impression does not allow for a literal interpretation encompassing a slight variation in the width of the tear impressions, the doctrine of equivalents would permit an insubstantial variation in the width of the tear impression.

Furthermore, while the drawings illustrating the single continuous line and the plurality of spaced apart short impressions show a relatively straight line, the language in the specification and in claim 1 fails to limit the claimed tear impression to the formation of a straight line. See, e.g., Specialty Composites v. Cabot Corporation, 845 F.2d 981, 987 (Fed.Cir. 1988) (noting that neither claims nor specification modified the term plasticizer as being external or internal and construed term to encompass either although examples in specification showed only external plasticizers). Moreover, spacing the relatively short tear impressions apart from one another leaves room for a slight differential in the straightness of the tear between the impressions. One skilled in the art would therefore interpret the claimed tear impressions to include a plurality of relatively short impressions which form a line which may have, at a minimum, a very slight variation in the straightness of the tear.

Turning to the meaning of the word edge in claim 1, the language reads that the tear impressions extend "inwardly from the edge of the container lid." ( '015 patent, col. 5, l. 22). The specification similarly states that the tear impressions "extend inwardly from edge (20)." ( '015 patent, col. 3, l. 5). The language of the specification and figures 2 and 4 clarify that edge (20) refers to the outer edge of the container lid. The specification illustrates and describes the rim-engaging means as having "an ascending wall element (14) and descending wall element (18)" with the descending wall element (18) pictured on the outer wall of the rim-engaging means in figures 2 and 4. The descending wall element (18) is further depicted as "projected outwardly [emphasis added] at its lower extremity [emphasis added] as shown as edge 20 [emphasis added] thereof." ( '015 patent, col. 2, l. 60-62 & 68; col. 3, l. 1-2). It is therefore apparent that to one skilled in the art the word edge in claim 1, as elaborated upon but not delimited in the specification, refers to the outer edge of the container lid.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

8 Likewise, with respect to claim 1 of the '167 patent ( '167 patent, col. 4, l. 50), the description in the specification of the tear impressions as extending inwardly from the edge (15) ( '167 patent, col. 3, l. 17), the further description in the specification of the edge (15) as part of the exterior descending wall element (13) ( '167 patent, col. 3, l. 10-11) of the rim engaging means (5) and the illustration of the edge (15) in figure 2 of the '167 patent all evidence that the edge referred to in claim 1 of the '167 patent denotes the outer edge of the container lid.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -
The choice of the word "from" in claim 1 ('015 patent, col. 5, l. 24), however, does not exclude allowance for a small space between the outer edge of the container lid and the first impression leading therefrom. As discussed above, the specification clarifies that the term tear impression may include a series of "spaced apart" ('015 patent, col. 3, l. 13) impressions. Accordingly, a small space may separate the outer edge from the first impression leading inwardly therefrom. Correspondingly, a small space may therefore separate the outer edge from the beginning of the claimed tear impression, as interpreted by one skilled in the art.

Dart also relies on the language in the specification that the tear impressions tear along "predetermined lines." ('015 patent, col. 3, l. 9). The pertinent language, however, exists in the specification and refers to the role of the tear impressions. Furthermore, the words in claim 1 are silent as to the demarcation of the tear impression as a predetermined line. This court therefore doubts whether a person skilled in the art reading this description of the role of the tear impressions as forming predetermined lines would also read this limitation into claim 1 to require that tear impressions must always form predetermined lines. 9

--- Footnotes ---

9 This court need not decide this issue, however, because assuming arguendo that claim 1 includes the limitation of a predetermined tear line, Bailey's expert opines that the accused product tears in this manner. (Docket Entry # 59, P 50). Given the varying interpretations of the characteristics of the accused product (Docket Entry # 49, P 31; see footnote number ten) summary judgment is improper.

--- End Footnotes ---

Turning to the other disputed characteristics of Dart's lids, Bailey's expert attests that such lids have a pair of spaced apart tear impressions which extend inwardly from the edge of the container lid. Each tear impression ends at a separate tear stop means pictured as a straight bar molded into the lids. (Docket Entry # 59, P 18 & Fig. 1, C). The drawings and physical exhibits of Dart's lids demonstrate that the tear impressions do not visibly extend to and touch the outer edge of the container lid.

Bailey's expert further describes Dart's lids as having two corrugated channels or pathways which this court finds correspond to the tear impressions in the '015 patent. According to Bailey's expert, each channel or pathway consists of a series of corrugations or impressions. (Docket Entry # 59, P 17). Bailey's expert characterizes each corrugation in the corrugated pathways as constituting a relatively short impression. Further, not unlike the space between the impressions described in the '015 patent ('015 patent, col. 3, l. 13-14), a narrow space separates each corrugation within the corrugated pathways. (Docket Entry # 59, P 50). According to Bailey's expert, each corrugation acts to direct the tear in a forward, preordained direction along the channel of the corrugations.

As disclosed in claim 1, tear impressions do not necessarily touch the edge of the container lid. Rather, they lead inwardly from the outer edge of the container lid. Such tear impressions may include a plurality of spaced apart, relatively short impressions. As expressed and discussed above, such tear impressions extend from the outer edge and may have a space between the outer edge and the beginning of the tear impression. Stated otherwise, because the term tear impression may encompass a series of spaced apart impressions, the first impression may have a small space between it and the outer edge of the container lid.

Whether Dart's lids have such a small space between the outer edge of the container lid and the first corrugation in the corrugated pathways cannot be decided on summary judgment. Both Bailey's and Dart's experts disagree about the characteristics of Dart's lids. According to Dart's expert the sawtooth corrugations in Dart's lids lie one to two millimeters from the interior edge of the inverted channel of the circumferential boundary of the container lid. (Docket Entry # 49, P 36). 10 Bailey's expert, however, states that the tear impressions in Dart's lids include the entirety of the corrugation channels and extend from the edge of the container lid. (Docket Entry # 59, P 60).

--- Footnotes ---

10 To the extent Bailey moves to strike (Docket Entry # 55) this paragraph of the second affidavit of Ralph W. MacKenzie ("MacKenzie") (Docket Entry # 49, P 36) or paragraphs 30 and 31, the motion is denied. MacKenzie properly qualifies as
an expert for purposes of the motion for partial summary judgment (Docket Entry # 5). He also adequately sets forth his reasoning with respect to paragraphs 30, 31 and 36. Finally, this court does not consider MacKenzie's testimony insofar as he opines about the reach of the terms in claim 1 of the '015 patent.

With respect to the issue of a predetermined line, Dart's expert depicts the sawtooth corrugations as not fostering the failure of the material along a predetermined line. (Docket Entry # 49, P 31). Bailey's expert, however, proffers a markedly different interpretation of the characteristics of the tear in Dart's lids. (Docket Entry # 59, P 50). Therefore, assuming arguendo for purposes of the motion for partial summary judgment only that claim 1 has such a limitation, there is a material issue of fact as to whether Dart's lids fall within this limitation.

Dart's expert also attests that the sawtooth corrugations extend perpendicular to the direction of the tear. (Docket Entry # 49, P 30). Again, having construed the term tear impression to include slightly perpendicular impressions, there is a material issue of fact as to whether Dart's lids meet this limitation. Similarly, having construed the term tear impressions to permit a slight variation in width of the spaced apart impressions, there is also a material issue of fact as to whether Dart's lids meet this limitation. In addition, whether the described sawtooth corrugations comprise impressions within the meaning of claim 1 is a materially disputed fact due to the differing descriptions of the corrugations given by Bailey's and Dart's experts.

In sum, in light of the differing factual descriptions of the accused product, summary judgment is improper with respect to whether Dart's lids lack the features of tear impressions extending inwardly from the outer edge of the container lid. Moreover, due to the different descriptions of Dart's lids in reference to the claims as construed above, partial summary judgment is also improper with respect to whether the differences between Dart's lids and the claimed "tear impressions extending inwardly from the edge of the container lid" ( '015 patent, col. 5, l. 22-23) are substantial. The corresponding tear impressions in Dart's lids are not altogether different from the claimed tear impressions in the '015 patent. The degree of the substantiality of the difference is an issue of fact given the present record before this court. Partial summary judgment under the doctrine of equivalents is therefore inappropriate.

The parties vigorously dispute the proper construction of the '015 patent claim element "a pair of spaced apart tear impressions extending inwardly form the edge of the container lid." Tear impressions in the '015 patent may appear in two basic forms, one being a single, continuous line and the other being a plurality of spaced-apart, relatively short impressions. '015 patent, col. 3, l. 10-14. Aside from the two basic forms of the tear impressions, the parties agree on several other characteristics of the tear impressions. For example, the parties do not contest the magistrate judge's conclusion that the
description of the tear impressions allows for a slight degree in variation in the width of the impressions in the case of a plurality of spaced-apart impressions. See Bailey I, 980 F. Supp. at 569. Nor do the parties dispute the ruling of the Federal Circuit that the tear impressions must be "physical, visible features on the patented lids . . . and are not inherent characteristics of the thermoformed plastic." Bailey v. Dunkin Donuts, Inc., 135 F.3d 775 (Fed. Cir. 1998), 1998 WL 4726 at *2 (restating the finding of the lower court and affirming) (unpublished decision). While the magistrate judge also concluded that the tear impressions allow for a very slight variation in the straightness of the tear, the parties agree that the '015 patent describes "tear impressions" in the context of the lid before it is open, and not qualities of the "tears" after the lid has been opened. Tr. 3, p. 62, l. 15-25. Although the width and spacing of the impressions will undoubtedly affect the performance of the tears, the straightness of the tears is not relevant to claim construction. At the heart of the dispute are two features: (1) the width and/or shape of the tear impressions and, (2) the meaning of the term "edge."

I begin with the language of claim 1 itself. "The language concerning tear impressions in claim 1, as read by one skilled in the art, demonstrates that tear impressions simply extend inwardly from the edge and terminate at a tear stop means." See Bailey I, 980 F. Supp. at 568. Thus, the language of the claim is wholly silent on the physical characteristics of the tear impressions aside from their positioning. For further guidance, therefore, I turn to the specification and prosecution history.

The specification states that the role of the tear impressions is to foster failure of the plastic material "along the predetermined lines defined thereby. Accordingly, said impressions may each be molded, embossed or scored as a single continuous line into the surface of lid (as shown in Fig. 1) or may each be performed as a plurality of spaced apart, relatively short impressions." 4 The drawings, figures 1 and 3, depict the tear impressions. Figure 1 pictures a single, uninterrupted, straight line from the outer edge of the container to the tear stop means. Figure 3 mistakenly illustrates the "plurality of spaced apart, relatively short impressions" as a continuous line. The '167 patent, however, correctly illustrates the language as a series of dashed lines. See Bailey I, 980 F. Supp. at 568-569.

As expected, the parties have starkly differing interpretations of the language in the specification. Dart argues that the specification sets the parameters for the tear impression structures. The tear impressions are both described in the specification as linear and in all instances are illustrated as linear. Dart contends that if the tear impressions could be any size or shape, then they would not foster the failure of the plastic material "along the predetermined lines defined thereby." By contrast, Bailey contends that the specification sets no limit on the size, shape, or width of the tear impressions, so long as the tear does not go astray and an access strip is formed. Neither party relies heavily on the prosecution history, and my review of that history does not reveal any matters material to the characteristics of the tear impressions. Bailey's view is illustrated in exhibit 26, which depicts wide, rectangular impressions. Bailey's expert, Dr. Steven S. Grossman, agreed on cross-examination that wide, rectangular impressions could meet the requirements of the '015 patent, provided that an access strip is formed once the lid is torn open and the tears do not go astray. I asked Dr. Grossman if there was any limitation on the width of the impressions. He responded:

THE WITNESS: No. I think the width again is not limited. They can have a width to them. They are not limited, again, to a sliver. They can have a width there so that they create a pathway for tear. So they do not have to have a specific width limited to a certain dimension. In fact --

THE COURT: At some point, though, the dimension can be so wide that you don't have a path.

THE WITNESS: Then the tear would go astray and they wouldn't work as a tear impression.

See Tr. 2, p. 37-38, ln. 22-25, 1-6. Dart's expert, Dr. David M. Parks, by contrast, opined that the impressions could be bold or thin, but qualified his statement with the limitation that the impressions retain their essential function of fostering failure along predetermined lines. Tr. 3, p. 120, ln. 21 (emphasis added).
I begin with the obvious observation that all tear impressions necessarily have some width. But how wide is too wide? Bailey's position that the tear impressions can be any width, so long as the tear does not go astray and an access strip is formed is dubious, at best. To interpret the patent in such a fashion wholly ignores the language in the specification that states the purpose of the "tear impressions" is to "foster failure . . . along predetermined lines defined thereby." Moreover, the only way for one skilled in the art to determine whether a tear impression is too wide is to tear the lid and see if the tear goes astray. In essence, Bailey's position is that a tear impression that functions properly, namely one that it does not allow the tear to go astray, is disclosed in the '015 patent. Such a construction is simply not consistent with the notion that the tear impressions define and predetermine a line, and is so broad that, were it taken as the proper statement of the scope of the term "tear impression" in the '015 patent, it would render that patent vulnerable to public notice attacks. See Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1303 (Fed. Cir. 1999) ("The district court erred by importing the functions of a working device into these specific claims, rather than reading the claims for their meaning independent of any working embodiment") (citing Transmatic, Inc. v. Gulton Indus., Inc., 53 F.3d 1270, 1278 (Fed. Cir. 1995) ("The district court erred by importing unnecessary functional limitations into the claim")). Consideration of the public notice function of the patent laws reinforces the conclusion that Bailey's proposed construction of the '015 patent should not be adopted.

I conclude that one skilled in the art would construe the term "tear impressions" as stated in the '015 patent to be physical, visible features on the lid, that may have some variation in width, and must predetermine and define a line in the context of a lid before it is torn open. A "line" is very narrow in proportion to its length, and can be straight or curved. The line formed by the tear impressions necessarily has some width, although the tear impressions cannot be so wide that they lose their essential characteristic of predetermining and defining a line.

5 In addition, the description in the specification accorded the plurality of spaced-apart relatively short impressions also leaves room for an interpretation that the impressions can vary in shape. For example, the impressions need not be dashes or dots, but could take the form of a variety of shapes, so long as the shapes maintain the essential characteristic of defining a line.

The parties next dispute the meaning of the term "edge" in the claim element requiring that the "tear impressions" extend "inwardly from the edge of the container lid." After reviewing all the evidence presented at the hearing on the matter, I now reaffirm my previous adoption of the magistrate judge's conclusion:

The language of the specification and figures 2 and 4 clarify that edge (20) refers to the outer edge of the container lid. The specification illustrates and describes the rim-engaging means as having 'an ascending wall element (14) and descending wall element (18)' with the descending wall element (18) pictured on the outer wall of the rim-engaging means in figures 2 and 4. The descending wall element (18) is further depicted as 'projected outwardly at its lower extremity as shown as edge 20 thereof.' ('015 patent, col. 2, l. 60-62 & 68; col. 3, l. 1-2). It is therefore apparent that to one skilled in the art the word edge in claim 1, as elaborated upon but not delimited in the specification, refers to the outer edge of the container lid.

The choice of the word 'from' in claim 1 (‘015 patent, col. 5, l. 24), however, does not exclude allowance for a small space between the outer edge of the container lid and the first impression leading therefrom. As discussed above, the specification clarifies that the term tear impression may include a series of 'spaced apart' (‘015 patent, col. 3, l. 13) impressions. Accordingly, a small space may separate the outer edge from the first impression leading inwardly therefrom. Correspondingly, a small space may therefore separate the outer edge from the beginning of the claimed tear impression, as interpreted by one skilled in the art.

Bailey I, 980 F. Supp. at 569-570 (emphasis supplied).

Therefore, in the case of a single continuous line, the tear impression must begin at the outer edge and travel inwardly to the tear stop means. When the tear impression consists of a plurality of spaced-apart, relatively short impressions, the parties agree that a small space separating the outer edge from the first impression may be appropriate. See Tr. 5, p. 30, l. 5-6. Such a space must be small enough that the tear impression retains its essential feature of "extending inwardly from the [outer]
edge of the container lid." 6

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

6 Nothing in the claim construction above precludes faulting of the polymeric sheet material at the end of each tear impression at the outer edge, as described in claim 3.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

4090

The '015 patent also claims that the tear impressions terminate "at separate tear stop means." This limitation is drafted in means-plus-function form pursuant to 35 U.S.C. § 112 para. 6. As disclosed in the specification, "the principal function of [the] tear stop means . . . is to prevent tear propagation beyond the inner end of each tear impression." The specification discloses several structures corresponding to the claimed tear stop means, including "small arcuate impressions," "arcuate slits," "cross or arcuate cuts," and "localized thickenings or mechanical reinforcements of the polymeric lid material located at the inner ends of the tear impressions." Bailey asserts that the single groove and ridge combination in the accused lids serves as the "separate tear stop means." He contends that the single groove and ridge structure in each of the accused lids provides separate tear stop means because when the accused lids are opened the tears terminate at separate points along this structure. Bailey asserts that since these termination points are spaced apart, they are separate tear stop means as claimed in the '015 patent.

4091

a. "Tear-wettable"

The parties dispute whether this term means "a high affinity for" tears or whether it means that tear fluid spreads out when exposed to a surface. The plaintiff contends that "tear-wettable" means "tear fluid has a tendency to spread out when exposed to a surface." According to the plaintiff, its construction is the meaning understood by one of ordinary skill in the art in the context of this patent. The defendants argue that "tear-wettable" requires that tears directly contact the surface layer and, therefore, the surface layer must have a high affinity for tears. In the context of this patent, the Court adopts the plaintiff's construction of "tear-wettable."

4092

B. "Teeth" and "Traction Teeth"

3

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

3 ECCO, in addition to adopting all of the arguments forwarded by the other Defendants, assert additional constructions and supporting arguments. Rather than filing its own brief, ECCO joined onto the briefs filed by Defendants Nike, Inc. ("Nike") and MacNeil Engineering Company, Inc. ("MacNeil") in a third case filed by Greenkeepers, Greenkeepers, Inc. v. Nike, Inc., No. 04-3747, which has since settled (Docket No. 106). (Taylor Made, Docket Nos. 55 & 66.) Accordingly, in this Memorandum, citations to "ECCO Opening" refer to Nike and MacNeil's Opening Claim Construction Brief (Nike, Docket No. 83), and citations to "ECCO Resp." refer to Nike and MacNeil's Responsive Claim Construction Brief (Nike, Docket No. 94).

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

- 4750 -
1. The Parties' Contentions

According to Greenkeepers, the patent specification indicates that the teeth, rather than biting into the ground, aim to "reduce damage to putting green surfaces," '047 Patent, col.2, l.2, and that Defendants' constructions exclude the patent's preferred embodiments. (Pls.' Opening 11-13.) Greenkeepers further aver that teeth need not "bite," as human and animal teeth do, because under their dictionary definition, they also encompass protrusions on combs, gears, or saws. (Pls.' Resp. 10-11.)

In response, Defendants aver that Greenkeepers repeatedly referred to the teeth in the covered cleats as "biting" into the ground, and distinguished prior art Curley cleats as not having true "teeth," because their protrusions did not pierce the ground. (Defs.' Resp. 10.) Defendant ECCO then takes issue with Greenkeepers' inclusion of "outwardly angled" in their proposed construction of "teeth" and "traction teeth," because the specification often describes the "teeth" or "traction teeth" as being "outward angled," thereby indicating that the "teeth" themselves need not be outwardly angled. (Def. ECCO's Resp. 15-17.)

Greenkeepers reply that during the prosecution history, they only described their teeth as "biting" into the "turf" grass, not the ground beneath the turf, in distinguishing prior art cleats that had essentially flat protrusions that stayed on the lawn surface. (Pls.' Resp. 11-14.)

2. Analysis

As a preliminary matter, the parties appear to agree that "teeth" and "traction teeth" have the same meaning, because these terms were used interchangeably in the patent specification (Defs.' Resp. 12-13), and because the parties each offer only one definition for both terms (Pls.' Opening 11; Defs.' Opening 16; ECCO Opening 20). Turning next to whether the construction of "teeth" and "traction teeth" should include references to outward angulation or bending, the Court finds that such references are inappropriate. The patent specification often uses "outward angled" to modify and add detail to "teeth" or "traction teeth," thereby suggesting that teeth need not have a predetermined angle. See, e.g., '047 Patent, col.5, 11.49-50 (describing the cleats as "each traction tooth having an axis ALT and an outwardly angled outer traction surface . . . to provide lateral stability. . . ."). As for flexibility, this has already been encompassed in the construction of "outward angled." As a result, the Court believes it would be redundant to add any description relating to flexibility into the definition of "teeth" and "traction teeth." Court will not construe "teeth" and "traction teeth" to include references to flexibility or bending, or outward angulation.

As for whether the teeth bite into the ground, Greenkeepers distinguished the teeth in its cleats from prior art cleats by emphasizing that Wilson cleats had "non-penetrating tip[s]" (Defs.' Resp., Ex. M, at SS_00005767), and that Dassler cleats'
"so-called arms . . . are really not teeth but are really cushioning arms," that "do not contemplate [the] studs digging in the turf of a golf course" (Defs.' Resp. Ex. J at 00006011-12, Ex. K at 00005991). As a result, prosecution disclaimer applies, because Greenkeepers "expressly disclaimed" coverage of golf cleats that do not penetrate at all into the grass. Omega Eng'g, 334 F.3d at 1323. As with "outwardly angled," however, the Court is concerned about the breadth of this disclaimer. Greenkeepers disavowed coverage of teeth that "dig . . . in the turf," but the Court has not found statements from the prosecution history distinguishing the cleats at hand from teeth that dig past the turf into the ground below, nor have Defendants identified any. The Court, thus, will construe "teeth," "traction tooth," and "traction teeth" as being "protrusions that penetrate into the turf below."

4 To the extent that Defendants contend that Greenkeepers' prosecution of the same patent in Europe distinguished prior art Curley cleats on a similar basis, the Court need not and will not address this contention, given that such evidence may be extrinsic, the intrinsic evidence alone demonstrates prosecution disclaimer, and thus, it is unlikely that such evidence will shed useful light on how to construe teeth and traction teeth.

(1) "a telecentric lens"

The term in question appears either directly or by reference in all claims of both the '653 and '690 patents. Plaintiffs assert that the term should be construed as "a special lens that collects parallel rays." Plaintiffs rely on the specification of the '690 patent which states, for example, that "a telecentric lens collects parallel rays." Defendant asserts that the term reflects an express disavowal to the use of dichroic mirrors and a limitation as to internal illumination.

Beginning with the claims in the '653 and '690 patents, there is no mention or reference in any of the claims to either dichroic mirrors or internal illumination. Claim 4 of the '690 patent, for example, expressly refers to collecting light from a multi-sample plate without noting the light source. Similarly, claim 1 of the '653 patent expressly refers to the lens collecting light and identifies the source as "light incident thereon [the multi-sample plate] or originating from a sample." ('653 patent, col. 21, In. 7-9).

Moving to the specifications, the '653 patent points to a description of "a telecentric lens." "A telecentric lens is free of parallax error." ('653 patent, col. 12, In. 39-40). n1 "A telecentric lens collects parallel rays, over the entire area of a well plate." ('653 patent, col. 12, In. 45-46). n2 In addition, the '653 and '690 specifications point directly to the two items raised by defendant. "A unique property of the present invention is that no dichroic is necessary. The telecentric lens is large, so there is room to install an illumination assembly within its body." ('653 patent, col. 12 In. 11-13). n3

In general, when a term implicitly suggests a broader meaning, there is no express disavowal. See Varco, L.P. v. Pason Sys. USA Corp., 436 F.3d 1368, 1375 (Fed. Cir. 2006). In Varco, the court noted that "the applicant could have used terminology such as 'relays are pneumatically operated valves' that expressly disavows alternative structures. As written, however, the specification contemplates that other structures may 'operate as relays' in addition to the preferred pneumatically operated valves." Id.

PUBPAT
In the case at bar, the Court finds that because the patentee made note that "there is room to install an illumination assembly," the Court finds no express disavowal. The term is written in open form and the patent neither requires or excludes the use of an illumination device. Similarly, the phrase "no dichroic is necessary" is not a disavowal of its use and the patent does not require or exclude use of a dichroic mirror. In both situations and as described in Varco, the drafter could have used terminology to expressly disavow dichroic mirrors or require internal (or external) illumination but left the text in open form.

Defendant also bases its assertion, in part, on a letter written by the inventor indicating the inventor's intent. However, such a letter is not within the patents or their prosecution history and is therefore extrinsic evidence. See Phillips, 415 F.3d at 1319. "[U]ndue reliance on extrinsic evidence poses the risk that it will be used to change the meaning of claims in derogation of the 'indisputable public records consisting of the claims, the specification and the prosecution history,' thereby undermining the public notice function of patents." Id. (quoting Southwall Techs. Inc. v. Cardinal IG Co., 54 F.3d 1570, 1578 (Fed. Cir.), cert. denied, 516 U.S. 987, 116 S. Ct. 515, 133 L. Ed. 2d 424 (1995)). However, despite what the inventor's intentions may have been, the patent itself serves the public notice function and is a part of the intrinsic evidence, as contrasted with the inventor's letter, which does not serve the public notice function and is extrinsic, and the term itself can be construed absent the extrinsic evidence. As such, the inventor's letter is not relevant to claim construction here.

As such, the Court finds that the term "a telecentric lens" is construed simply as "a special lens which collects parallel rays."

(4) "telecentric lens means for peering into the well"

The term in question appears in claim 5 of the '653 patent. Plaintiffs assert that the term should be construed to not limit the claim to the reference of a telecentric lens. Plaintiffs assert that because the structural component, the telecentric lens, is expressly recited in the claim, it is not appropriate to treat the phrase as a means-plus-function limitation per 35 U.S.C. § 112, P6. In contrast, Defendant asserts that because (1) the phrase's express statement is in means-plus-function format, together with (2) the patentee's assertion of applying 35 U.S.C. § 112, P6 during the prosecution history, the Court should treat "telecentric lens" as a limitation to the claim.

"An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112 P6. "Whether certain claim language invokes 35 U.S.C. § 112, [P]6 is an exercise in claim construction and is therefore a question of law." Personalized Media Commc'ns., L.L.C. v. ITC, 161 F.3d 696, 702 (Fed. Cir. 1998).

The use of the word "means" in the claim invokes a presumption that the patentee invokes the statutory mandate for means-plus-function clause. Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1302 (Fed. Cir. 1999), cert. denied, 528 U.S. 1115, 120 S. Ct. 933, 145 L. Ed. 2d 812 (2000).

Two specific rules, however, overcome this presumption. First, a claim element that uses the word 'means' but recites no function corresponding to the means does not invoke § 112, [P]6. Second, even if the claim element specifies a function, if it also recites sufficient structure or material for performing that function, § 112, [P]6 does not apply.

Id. (internal citation omitted). The Court begins its construction by adopting the presumption that the patentee invoked the means-plus-function format. However, moving directly to the second exception, the claim element does specify a function ("peering into the well") but also recites a sufficient structure for performing that function (the "telecentric lens"). Although Defendant asserts that such function is insufficient without illumination, the specification does recognize that such illumination can be from the sample within the well and, as such, external illumination is not necessary and the telecentric lens alone represents sufficient structure.

Defendant also asserts that through the prosecution history, Plaintiffs invoked 35 U.S.C. § 112 P6 and, as a result, prosecution history estoppel requires the Court to construe the telecentric lens as a limitation. To begin with, the prosecution
history directs the examiner that the claim should be considered as structure under § 112 P6. However, once the applicant directs the examiner to view the telecentric lens as a structure, the applicant directs the examiner toward the second rule to overcoming the means-plus-function presumption of § 112 P6. The claim was subsequently accepted unchanged by the examiner. In addition, the prosecution history makes no explicit mention of this claim relative to means-plus-function, nor does the examiner explicitly accept it as such. Because the prosecution history points directly at the second rule to overcoming the means-plus-function presumption, the prosecution history supports that the "telecentric lens" is not a limitation to the claim.

--- Footnotes ---

--- End Footnotes ---

As a matter of law, this Court construes that the term "telecentric lens" is a sufficient structure to support the function of "peering into the well." The Court does not accept Defendant's argument of construing the telecentric lens as a limitation stemming from construing the phrase in means-plus-function format of 35 U.S.C. § 112 P6.

--- 4095 ---

Defendant also moves for reconsideration of the term "telecentric lens means for peering into the well" on the basis that the Court: (a) omitted relevant language from the construction, and (b) misinterpreted the comments made during prosecution when this claim was added to the patent. The relevant claim language is as follows:

telecentric lens means for peering into the well of said at least one sample in order to improve the collection of light therefrom, the light collected by said telecentric lens means being transmitted therethrough;

(a) Omission of Relevant Language

The Court's May 24, 2006 Opinion construed, as a matter of law, that the term "telecentric lens" is a sufficient structure to support the function of "peering into the well," in connection with claim 5 of the '653 patent. In particular, the Court rejected Defendant's argument that the phrase's express statement is in a means-plus-function format, and, as a result, "telecentric lens" should be treated as a limitation to the claim. The Court, in reaching this decision, focused on the issue of whether the word "means" used in the claim language invokes the means-plus-function format 35 U.S.C. § 112 P6. (May 24 Op. at 16). Ultimately, the Court found that, in this case, it did not.

Defendant now argues that the Court's May 24 Opinion did not address all the functional language present in the claim limitation. In particular, Defendant argues that the Court only addressed a "truncated" version of the first part of the limitation - "telecentric lens for peering into the well" - and never addressed the latter part of the phrase which stated "in order to improve the collection of light therefrom." (Def. Br. at 14). According to Defendant, when the additional language is considered, it becomes apparent that the telecentric lens, alone, is not capable of achieving the function of "improving the collection of light" and that other unmentioned structures are thus necessary to accomplish this task. (Def. Br. at 15). Thus, Defendant argues, that because the claim does not contain sufficient structure to perform the function, the claim limitation should be construed in the means-plus-function format, under 35 U.S.C. § 112 P 6. (Id.).

In construing the term "telecentric lens" as a sufficient structure to support the function of "peering into the well," the Court's May 24 Opinion did not expressly address whether the term "telecentric lens" is a sufficient structure also for performing the function of "improving the collection of light therefrom." Therefore, the Court finds that reconsideration on this issue is warranted.

As set forth in the Court's May 24 Opinion, "an element in a claim for a combination may be expressed as a means or step
for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112 P 6. Additionally, "whether certain claim language invokes 35 U.S.C. § 112, [P] 6 is an exercise in claim construction and is therefore a question of law . . . ." Personalized Media Comm'ns, L.L.C. v. ITC, 161 F.3d 696, 702 (Fed. Cir. 1998).

Generally, use of the word "means" invokes a presumption that the patentee invokes the statutory mandate for means-plus-function clause. Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1302 (Fed. Cir. 1999), cert. denied, 528 U.S. 1115, 120 S. Ct. 933, 145 L. Ed. 2d 812 (2000). However, even where the claim element specifies a function, § 112, P 6 does not apply if it also recites sufficient structure or material for performing that function. Id. at 1302.

In its Opening Claim Construction Brief, Defendant provided a proposed construction for certain claim language in claim 1 of the '653. There, the claim language at issue was:

a telecentric lens suitable for imaging said multi-well plate positioned to collect light from said plate, the collection of light from said at least one sample being improved owing to the ability of the telecentric lens to peer into the well, the collected light being transmitted through said telecentric lens;

Interestingly, Defendant proposed the following construction of said claim language:

a telecentric lens that can be used for creating an image of a multi-well plate, and that is positioned so that it can collect light from the multiple-well plate, the collection of light from the plate being improved due to the ability of the telecentric lens to eliminate parallax error,

(Def. Claim Construction Br., App. at 1) (emphasis added).

Additionally, column 12, lines 39-48 of the '653 patent state the following:

The present lens is telecentric. A telecentric lens is free of parallax error. Images of deep, narrow targets, made with standard lenses, exhibit parallax error. Circular targets at the center of the image are seen as true circles. However, the lens peers into lateral targets at an angle. Therefore, these lateral targets are seen as semilunar shapes. In many cases, one cannot see the bottom of a well at all. A telecentric lens collects parallel rays, over the entire area of a well plate. Thus, it does not peer into any wells at an angle and is free of parallax error.

'653 patent, col. 12, In. 39-48 (emphasis added).

Having reviewed the language of the '653 patent, itself, as well as Defendant's proposed construction of similar language contained in claim 1 of the '653 patent, the Court determines that the "telecentric lens" contains sufficient structure to perform the additional function of "improv[ing] the collection of light," based on its ability to eliminate parallax error. Accordingly, the Court rejects Defendant's argument that "telecentric lens" should be construed as a limitation stemming from construing the phrase in a means-plus-function format of 35 U.S.C. § 112, P 6. Therefore, the conclusion reached by the Court in its May 24 Opinion remains unchanged, as the Court hereby construes that the term "telecentric lens" is a sufficient structure to support the function of "peering into the well," as well as the function of "improv[ing] the collection of light therefrom." As such, upon reconsideration, the Court affirms its May 24, 2006 Opinion and Order.

1. "Telescope"

The first term that the parties disputed was the word "telescope." "Telescope" appears in every claim in the patent, either expressly or by reference. Id. at 6:29-8:22. As used in the '908 Patent, this Court construes the term "telescope" to include both "reflecting telescopes," which use mirrors as optical elements, and "refracting telescopes," which use lenses as optical elements. n4
n4 It is also noted that prisms have been used as optical elements in both reflecting and specialized refracting telescopes. (See Markman Hearing, Def. Ex. B, Isaac Newton, Optics 422-23 (1717); Def. Ex. C, John Texreau, How to Make a Telescope 107 (1957); Markman Tr. at 19:14-21.)

Plaintiff contends that the term "telescope" should be restricted to a "Newtonian telescope." n5 (See Plaintiff's Reply Claim Construction Brief, Mar. 10, 2005, "Pl.'s Reply Br." at 3.) Defendant, in contrast, argues that "telescope" is much broader than plaintiff alleges, urging that the term be construed to include both "reflecting telescopes" and "refracting telescopes," thus comporting with the term's dictionary definition. (See Defendant's Brief Addressing Claim Construction, "Def.'s Opp. Br." at 3.) As discussed supra, a court must begin its claim construction analysis by analyzing the language of the claims themselves.

n5 For the most part, Newtonian Telescopes are a subgroup of reflecting telescopes. (Markman Tr. at 4:9-11.)

a. Doctrine of Claim Differentiation

"The doctrine of claim differentiation ... creates a rebuttable presumption that each claim in a patent has a different scope." Dow Chem. Co. v. United States, 226 F.3d 1334, 1341 (Fed. Cir. 2000). The doctrine is implicit in 35 U.S.C. § 112, P4, which states that "a claim in dependent form shall contain a reference to a claim previously set forth and then specify a further limitation of the subject matter claimed." (emphasis added). Thus, under the doctrine, a dependent claim and a corresponding independent claim should not be construed to have the same scope; the dependent claim should have an additional limitation. The Federal Circuit recently reaffirmed the doctrine of claim differentiation, without using that title, in Phillips, when it stated that "the presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." 2005 U.S. App. LEXIS 13954, 2005 WL 1620331, at *7 (citing Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004)). The doctrine precludes interpretations of claim language that render dependent claims too broad or independent claims too narrow, but it should not be used to interpret an independent claim too broadly either. See Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, (Fed. Cir. 1987) ("Whether or not claims differ from each other, one can not interpret a claim to be broader than what is contained in the specification and claims as filed.") (citation omitted).

b. Analysis

The doctrine of claim differentiation applies to this situation and resolves the dispute as to the definition of "telescope" in favor of defendant, i.e., that "telescope" includes both reflecting and refracting telescopes rather than being limited to Newtonian telescopes. The term "Newtonian telescope" appears in claim 5 of the '908 Patent. '908 Patent at 6:42-43 ("The method of claim 1, further comprising locating the optical element in a Newtonian telescope."). Claim 5 is dependant on claim 1, which describes: "[a] method of aligning an optical element in a telescope." Id. at 6:30 (emphasis added). The "Newtonian" limitation on the word "telescope" in claim 5 would be unnecessary if a person of ordinary skill in the art would have understood "telescope," as used in claim 1, to be restricted to Newtonian telescopes. Based on the doctrine of claim differentiation, the term "telescope" should not be restricted to "Newtonian telescopes."

The next question is what the term "telescope" includes, if it is not limited to Newtonian telescopes. Plaintiff argues that if "telescope" is not limited to Newtonian telescopes, it should be limited to "reflecting telescopes," which would include Newtonian telescopes as a subgroup. (Markman Tr. at 6:12-13.) n6 The doctrine of claim differentiation answers this question as well. The term "reflecting telescope" appears in claim 4. '908 Patent at 6:40-41. Claim 4 is "the method of claim 1, further comprising locating the optical element in a reflecting telescope." Id. (emphasis added). Applying the doctrine of claim differentiation, the term "telescope," as used in claim 1, presumptively cannot be limited to "reflecting telescopes," which is the limitation added in claim 4. Therefore, this Court looks to the specification to determine whether the term

- 4756 -
"telescope" includes refracting telescopes, as defendant suggests.

n6 Citations to the Markman hearing transcript reference the page and line numbers in the form Page(s):Line(s).

Plaintiff asserts that the specification "does not describe any method for using this invention to align a [refracting] telescope," and cites Phillips for the proposition that the claims must be consistent with the specification. (Markman Tr. at 6:4-5.) Nonetheless, as plaintiff concedes, the specification expressly states that "the present invention may be used to align refracting telescopes." '908 Patent at 6:11, 19-21 (emphasis added). In fact, the specification even provides a diagram of the invention being used with a refracting telescope. Id. at Fig. 15. Since the patent mentions refracting telescopes in the specification, included a drawing for the invention with a refracting telescope, and uses "reflecting telescope" as the limitation in a dependent claim, it is clear from the intrinsic evidence that the term "telescope," as used in the claims, includes both reflecting and refracting telescopes. n7

n7 Claims 10, 15, 18, and 20 use the term "telescope" without any dependent claims that limit the term; however, this is of no consequence because claim terms are to be construed consistently across all claims. See Southwall Tech., Inc. v. Cardinal IG Co. 54 F.3d 1570, 1579 (Fed. Cir. 1995); accord Phillips, 2005 U.S. App. LEXIS 13954, 2005 WL 1620331 at *6 ("Because claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claims.").

B. Claim 10

The parties also disagree on the proper construction of claim 10. The court repeats claim 10 here for ease of reference:

In a pull-type harvesting machine as claimed in [claims 1-9], said steering structure including telescoping linkage having a front pivotal connection with the tongue at a point which is at least approximately equidistant from said opposite ends of the telescopic section.

The parties join issue first on the meaning of the term "telescoping." Defendant argues that the term should be construed to encompass only linkages that have overlapping sections, as if in overlapping cylindrical sections. Plaintiff argues that the term is broader, and encompasses any sliding linkage allowing for the adjustment of length.

The court agrees with defendant and holds, as a matter of law, that the term "telescoping linkage" as used in the '859 patent means a linkage having overlapping cylindrical sections. The ordinary meaning of the term telescoping is "to slide or pass one within another like the cylindrical sections of a hand telescope." Webster's Third International Dictionary, 2351 (1986). The court believes the term telescoping is simply too narrow to encompass the entire class of sliding linkages which allow for the adjustment of length.

Gargoyles argues that "temples pivotally secured to the outer edge of the lenses" refers to conventional side pieces or arms
(that may include hinges with legs or end pieces), which are attached to the lenses rather than to a frame so that they can be folded and are located outside the wearer's field of vision.

Aearo contends that "temples," elements used to secure the lenses to the ears, as that term is used in the '611 Patent, cannot include end pieces and must be directly attached to the outer edge of the lenses rather than to the surface of the lenses inside the outer edge.

Neither the claims nor the Specification nor the PTO file of the '611 Patent expressly defines the word "temple." Dependent Claim 8, however, adds a relevant limitation with respect to the attachment of temples to the lenses:

The eyeglasses of Claim 1, further including a pair of mounting pads integrally formed at the outer edges of respective lenses, and a hinge having one mounting leg embedded in each mounting pad and another portion secured to a respective temple.

'611 Patent, col. 4, 11. 52-56. Because that dependent claim cannot exceed the scope of independent Claim 1, "temples pivotally secured to the outer edge of the lenses" must include temples secured to a hinge with a mounting leg, which are secured to mounting pads which are, in turn, integrally formed to the outer edge of the lens. In other words, a temple may be secured to the lens by an intervening means that allows it to rotate.

In the Specification, the description of the "Best Mode" of the invention reiterates that broad construction:

A pair of temples 18 of conventional design are secured to the lenses 12 with conventional hinges 20. One leg 22 of each hinge 20 is embedded in respective mounting pads 24 integrally formed along the outer edge of each lens. The illustration corresponding to that description depicts the "temples" as the sidepieces or arms of the glasses which would extend along a wearer's temples. The means of securing the temples is a separate piece, a conventional hinge with a leg, that permits the temple to rotate. In addition, the illustrations show that the point of attachment of each temple is inside of the outermost edge of the lenses so that, when the temples are in the fully opened position, the end of each temple touches, or almost touches, the outer edge of the lens. The use of the word "conventional" to describe both the design of the temples and the hinges suggests that neither the temples themselves nor the securing means are further limited to distinguish the disclosed invention from prior art.

Based upon the intrinsic evidence, this Court construes "temples pivotally secured to the outer edges of respective lenses" to mean sidepieces or arms extending along the wearer's temples which are fastened to the lenses by a means or method that allows them to pivot or rotate at a place on the exterior portion of those lenses near the wearer's temples.

Claim Term | Plaintiff's Proposed Construction | Defendants' Proposed Construction
--- | --- | ---
"temporarily" | "lasting or used for a limited time" | "used in connection with the elevator installation during modernization, and removed after modernization is complete"

Plaintiff notes that the term "temporarily" is not expressly defined in the specification and therefore cites to the dictionary definition of "lasting or used for a limited time." See American Heritage Desk Dictionary 843 (4th ed. 2001). Plaintiff asserts that the term "temporarily" is used to describe the (1) operation of an elevator during modernization, and (2) the connection of the modernizing device to an elevator control. ('861 Patent, col. 11:5-10; id. col. 12:49-53.) Plaintiff contends that its proposed construction is consistent with the claim language because it denotes that the use contemplated will only persist during the limited time of the modernization process.

Defendants concede that Plaintiff's construction comports with the dictionary definition of "temporarily." Defendants argue, however, that the meaning of "temporarily" must be construed in the context of the patents in order to provide the
appropriate meaning. Defendants note that the construction provided by Plaintiff does not provide any definitive time limitation (e.g., one month or one year), and therefore it is too vague. Defendants argue that the only proper context for understanding the term "temporarily" is to link it to the modernization process itself. Thus, Defendants' proposed construction defines the term with respect to its relation to the modernization process.

Although Plaintiff's proposed construction is consistent with the ordinary meaning of the term "temporarily," the term is best understood as measuring the time in which the modernization process takes place. Plaintiff concedes that the relevant guidepost for understanding the term "temporarily" relates to the time during which the modernization steps are completed. Therefore, Defendants' proposed construction best comports with the scope of the term "temporarily" by tying it directly to the process to which the term applies. See Toro Co. v. White Consol. Indus., Inc., 199 F.3d 1295, 1299 (Fed. Cir. 1999) ("[W]ords of ordinary usage must nonetheless be construed in the context of the patent documents."). In other words, the best (and seemingly only) way to comprehend the meaning of "temporarily" is to relate it to the process which will determine how long "temporarily" will actually be. As explained by the Federal Circuit in Toro:

As this case well illustrates, the dictionary definitions of common words are often less useful than the patent documents themselves in establishing the usage of ordinary words in connection with the claimed subject matter. This is not an issue of the richness of language, or variety or imprecision in the usage of words. Determining the limits of a patent claim requires understanding its terms in the context in which they were used by the inventor, considered by the examiner, and understood in the field of the invention.

In judicial "claim construction" the court must achieve the same understanding of the patent, as a document whose meaning and scope have legal consequences, as would a person experienced in the technology of the invention. Such a person would not rely solely on a dictionary of general linguistic usage, but would understand the claims in light of the specification and the prior art, guided by the prosecution history and experience in the technologic field.

Id. In light of the context provided by the Patents-in-Suit, the Court finds that the term "temporarily" means "used in connection with the elevator installation during modernization, and removed after modernization is complete."

C. "temporarily adhering"

The term "temporarily adhering" can be found in the '697 patent, and Plaintiffs propose the following construction of the term: "To temporarily hold fast or stick by or as if by gluing, suction, grasping, fusing or otherwise." JCC at 7:12-19. On the other hand, Defendants simply incorporate by reference their proposed construction of "temporarily coupling." Id. ("temporary physical securing, adhering, or affixing, not mere physical contact, between the leading end of the outer label and the inner label"). Although there seems to be no genuine dispute as to the meaning of the term "temporarily adhering," the Court adopts Plaintiffs' proposed construction of the term because it is consistent with the relevant definition contained in Merriam-Webster's Collegiate Dictionary ("to hold fast or stick by or as if by gluing, suction, grasping, or fusing").

The '037 Patent is a continuation of the '578 Patent. The application leading to its issuance was filed on October 6, 1997. It was issued on July 20, 1999.

The only Claim of the '037 Patent over which there is a dispute is Claim 6, which provides:

A wire for use in formation of an occlusion within a cavity used in combination with a catheter comprising:

a core wire having a tip portion end; and

a detachable elongate tip portion extending said core wire adapted to being packed into said cavity to form said occlusion

- 4759 -
in said cavity, said detachable elongate tip portion being temporarily coupled to said distal end of said core wire and detachable from said core wire without applying any force by said distal tip to any surface within said body cavity, whereby occlusion of said cavity can be performed.

The parties dispute the proper construction of the phrase "temporarily coupled to." "Temporarily" is a common adverb meaning "for a time only; for the time being." See Webster's New Twentieth Century Dictionary, 1878 (2d ed. 1983). The phrase "coupled to," is a commonly used non-technical phrase meaning "attached to."

The language of Claim 6 supports giving the phrase "temporarily coupled to" its common meaning. The phrase is used with respect to the relationship between the "elongate tip portion" and the "distal end of the core wire." The two are "temporarily coupled" and are "detachable." Further, except for its use in the claims, the phrase "temporarily coupled to" is not used or otherwise defined in the specification. A person of ordinary skill in the art would give the phrase its plain and commonly understood meaning.

The Court construes "temporarily coupled" as it is used in Claim 6 of the '037 Patent to mean: attached to until detached from.

B. "temporarily coupling"

The term "temporarily coupling" is used throughout both patents. 6 Merriam-Webster's Collegiate Dictionary defines "coupling" as "to fasten together." However, the parties' dispute more precisely relates to the definition of "temporarily." Plaintiffs contend that "temporarily coupling" means "joiner, pairing, or bringing together to momentarily connect." JCC at 8:12-20 (emphasis added). On the other hand, Defendants argue that the "term requires a temporary physical securing, adhering, or affixing, not mere physical contact, between the leading end of the outer label and the inner label." Id. (emphasis added). However, the definition of "temporarily"--"lasting for a time only"--is broad enough to encompass both "momentary" contact as well as "physical securing, adhering, or affixing." See The Merriam Webster Dictionary, Home and Office Edition, 1995. Consequently, the term is not limited in the way Defendants suggest. In fact, based on this definition, the only limitation on "temporarily" is that it not be permanent., i.e., eventually allowing the outer label to rotate about the inner label and/or container.

This definition is also consistent with the respective patent specifications. The '269 patent specification describes several methods of temporarily coupling the leading end of the outer label with the inner label, including (1) a blast of air or other gas; (2) moisture; (3) a holding or pressing apparatus; (4) vacuum pressure; or (5) a static electric charge. Id. at 5:61-6:13. 7 The '697 patent, on the other hand, describes a method by which "a release tab is removably attached to a rotatable label to facilitate attachment of the label to a container. The release tab is adhered to the container, or to a label affixed to the container, to secure the label to the container while the label is wrapped around the container. The release tab is then detached from the label once the label is wrapped about the container to permit the label to rotate about the container." Id. at 1:64-2:4.

This definition is also consistent with the respective patent specifications. The '269 patent specification describes several methods of temporarily coupling the leading end of the outer label with the inner label, including (1) a blast of air or other gas; (2) moisture; (3) a holding or pressing apparatus; (4) vacuum pressure; or (5) a static electric charge. Id. at 5:61-6:13. 7 The '697 patent, on the other hand, describes a method by which "a release tab is removably attached to a rotatable label to facilitate attachment of the label to a container. The release tab is adhered to the container, or to a label affixed to the container, to secure the label to the container while the label is wrapped around the container. The release tab is then detached from the label once the label is wrapped about the container to permit the label to rotate about the container." Id. at 1:64-2:4.

7 The '269 patent specification also states that "[a] leading end is temporarily affixed to the container while the outer label is wrapped around the container." '269 patent at Abstract (emphasis added).
Therefore, the Court construes "temporarily coupling" to mean the following: to fasten together for a limited time, and, upon uncoupling, allowing the outer label to rotate about the inner label and/or container.

4103

"Tension"

Here too no Markman-type construction seems to be required that would add a definition beyond the ordinary English language meaning of the term "tension." Once again Dometic offers up an artificial construct to advance its position, a construct in which the connector that is the subject matter of the invention must support the entire weight of the awning (repeating the notion of the "series" connector), although the patent claims do not prescribe any limitations in terms of weight—let alone the quantity of weight involved. In short, the '172 Patent's references to "tension" will go to the jury without the interposition of any judicial gloss.

4104

1. "tension member"

Schindler proposes that "tension member" be construed to mean "structure which is stretched taut." Schindler's construction is premised upon the WEBSTER'S DICTIONARY definition of the term, which defines tension as "the act of stretching or the condition or degree of being stretched to stiffness: tautness." In its responsive brief, Otis suggests that the Court construe "tension member" as a "structure which during use is stretched or under stress."

Each parties' proposed construction will be adopted in part. The Court adopts Schindler's interpretation that requires the tension member to be "stretched taut." However, as Otis argues, the phrase "during use" is necessary to provide a clear definition of the term. The Court will, thus, construe "tension member" as a "structure which, during use, is stretched taut."

3 Otis asserts that including the word "taut" will lead to a dispute over the definition of "taut." This result, however, is no different than if the Court were to use other words that have been proposed such as "under stress" or "stiffness."

4105

1. "Terminal"

In the Markman proceeding, KEI took the position that "terminal" was appropriately construed as a structure "attached to the end of an elongated barrier that is anchored" to prevent an impacting vehicle's perpendicular movement, but asserted that the construction should be broad enough to include a device attached to the end of a truck or work vehicle parked in the roadway. 17 KEI's proposed claim construction defined "terminal" as a device that attaches to the "end of an elongated barrier or other similar roadside hazard." Trinity's proposed claim construction defined "terminal" as "a device attached to the end of an elongated barrier. . . . A device attached to a truck or work vehicle is not a terminal." (Docket Entry No. 90, p. 19). This court rejected Trinity's and partially adopted KEI's proposed construction. This court construed "terminal" as "a
A device attached to the end of an elongated barrier that is anchored to the roadside, or attached to the end of a fixed roadside hazard, that prevents an errant vehicle's movement perpendicular to the roadway and . . . absorbs energy when a vehicle hits the terminal itself.” (Id.).

A review of the record reveals that this court's construction of "terminal" is consistent with the interpretive principles explained in Phillips. The specification of the 003 Patent consistently describes a "terminal" as attached to structures that are anchored or fixed along the roadway. In one embodiment, the roadside obstacle is a guardrail, a longitudinal barrier, connected to the ground by posts. (Docket Entry No. 65, Ex. 1, 003 Patent, col. 4, ll. 6-7, Figs. 1-4). In another embodiment, the roadside hazard is a "hard structure such as an overpass or the like." (Id. at col. 8, ll. 5-7, Fig. 14).

In the Markman analysis, this court drew on definitions in the Transportation Research Board National Research Council National Cooperative Highway Research Program Report 350 ("NCHRP Report 350"). This court looked to the Report 350 as evidence of the ordinary meaning of "terminal" in the field of highway safety design. The definition of "terminal" that this court found supported by the Report 350 is consistent with the use of the term in the patent claims and specification. Use of the Report 350 in the claim construction analysis is consistent with Phillips.

The NCHRP Report 350 was published by the Transportation Research Board in 1993 to provide "recommended procedures for evaluating the safety performance of various highway safety features." (Docket Entry No. 146, Ex. 15, T00517). The Federal Highway Administration requires roadway safety devices used on the national highway system to meet performance standards set out in the NCHRP Report 350. Id. ("This report is recommended to highway design engineers, bridge engineers, safety engineers, researchers, hardware developers, and others concerned with safety features used in the highway environment."). 18 Dr. Sicking was an author of the report. The glossary of the NCHRP Report 350 includes the following definitions:

Crash Cushion A device designed primarily to safely stop a vehicle within a relatively short distance. A redirective crash cushion is designed to contain and redirect a vehicle impacting downstream from the nose of the cushion. A nonredirective crash cushion is designed to contain and capture a vehicle impacting downstream from the nose of the cushion.

Terminal A device designed to treat the end of a longitudinal barrier. A terminal may function by (a) decelerating a vehicle to a safe stop within a relatively short distance, (b) permitting controlled penetration of the vehicle behind the device, (c) containing and redirecting the vehicle, or (d) a combination of a, b, and c.

Longitudinal Barrier A device whose primary functions are to prevent vehicular penetration and to safely redirect an errant vehicle away from a roadside or median hazard. The three types of longitudinal barriers are roadside barriers, median barriers, and bridge rails.

Truck-Mounted Attenuator (TMA) An energy-absorbing device attached to the rear of a truck or utility vehicle. A TMA is designed to provide a controlled stop of a vehicle impacting the rear of the truck.

(Id., T00695-96). According to the Report 350, "terminals" are only applied to the end of longitudinal barriers-roadside barriers, median barriers, and bridge rails -- that are attached or anchored to the road. Such devices are distinct from energy-absorbing devices that are designed to be attached to the rear of a truck or utility vehicle. Not only are these uses of the term "terminal" consistent with the use of the term in the claims and specification of the 003 Patent, the Report 350 involves none of the problems in using dictionaries that the court identified in Phillips.
In Phillips, the court identified several reasons why extrinsic evidence is often considered less reliable than the intrinsic evidence of the patent itself. Extrinsic evidence "does not have the specification's virtue of being created at the time of patent prosecution for the purpose of explaining the patent's scope and meaning." 415 F.3d at 1318. Extrinsic publications may not be written by or for skilled artisans in the field of art of the patent. And extrinsic evidence such as expert reports and testimony that is generated at the time and for the purpose of litigation, can suffer from bias not present in intrinsic evidence. Id. Dictionary definitions can be overly broad:

The problem is that if the district court starts with the broad dictionary definition in every case and fails to fully appreciate how the specification implicitly limits that definition, the error will systematically cause the construction of the claim to be unduly expansive. The risk of systematic overbreadth is greatly reduced if the court instead focuses at the outset on how the patentee used the claim term in the claims, specification, and prosecution history, rather than starting with a broad definition and whittling it down.

Dictionaries, by their nature, provide an expansive array of definitions. General dictionaries, in particular, strive to collect all uses of particular words, from the common to the obscure. By design, general dictionaries collect the definitions of a term as used not only in a particular art field, but in many different settings. In such circumstances, it is inevitable that the multiple dictionary definitions for a term will extend beyond the "construction of the patent [that] is confirmed by the avowed understanding of the patentee, expressed by him, or on his behalf, when his application for the original patent was pending."

Id. at 1321 (quoting Goodyear Dental Vulcanite Co. v. Davis, 102 U.S. 222, 227, 26 L. Ed. 149, 1881 Dec. Comm'r Pat. 131 (1880)).

The NCHRP Report 350 -- a technical report commonly used to test highway safety devices -- does not present the overbreadth problems encountered when using a general dictionary with multiple definitions. The definitions contained in the report were selected by experts in the roadside safety field, including Sicking, one of the inventors listed in the 003 Patent and the 820 Patent. The Report 350 was intended to be used by designers and engineers in the highway safety industry. The Report 350 was published in 1993, and Sicking and Pfeifer filed the application for the 003 Patent on November 7, 1994; the period between the two was short. The reliability concerns articulated by the court in Phillips -- timing, audience, and bias -- are not present to undermine the probative value of the definitions used in the Report 350. Given the purpose of the Report 350, Sicking's role as an author, and the publication date, this court's use of the report is consistent with the rule that a claim term must be construed as it is understood by a person of ordinary skill in the art at the time the application was filed, with primary emphasis on the specification and prosecution history. The Report 350 provides contemporaneous technological context to the disputed term, "terminal," and is consistent with the use of the term in the claims, the specification, and the file history. See Moba, B.V. v. Diamond Automation, Inc., 325 F.3d 1306, 1315 (Fed. Cir. 2003) ("The best indicator of claim meaning is its usage in context as understood by one of skill in the art at the time of invention."). In short, the analysis used in the construction of "terminal" is not inconsistent with the court's instruction in Phillips.
This term appears in Claims 1 and 16. Plaintiff's proposed construction is as follows: "a device attached to an electrical apparatus for convenience in making connections, such as a tang." Defendants assert that this phrase does not need to be construed, but, alternatively, offer the following construction: "point of connection." Both parties cite general purpose dictionaries in support of their proposed constructions, and Plaintiff also references the language of the claims and the specification. The Court finds that construction of "terminal" is appropriate, and also finds that this is a situation where "claim construction . . . involves little more than application of the widely accepted meaning of commonly understood words." Phillips, 415 F.3d at 1314. Webster's College Dictionary, cited by Defendants, sets forth twelve definitions for the word "terminal," the most relevant being "the mechanical device by which an electric connection to an apparatus is established." Similarly, Webster's Ninth New Collegiate Dictionary, cited by Plaintiff, has among its several definitions of the word "terminal" the following: "a device attached to the end of a wire or cable or to an electrical apparatus for the convenience of making connections." Additionally, looking at both the context of the language of Claims 1 and 16 as well as the specification of the '015 Patent, a "terminal" in the '015 Patent includes a tang attached to the commutator bar for allowing a connection between the armature wire and the commutator bar. Accordingly, the Court shall construe "terminal" consistent with Plaintiff's proposed construction as "a device attached to an electrical apparatus for convenience in making connections, such as a tang."

B. Does the MPS 350 Have a "Terminal"?

KFI defines "terminal," as follows:

The claimed "terminal" is a part that forms the end of an elongated barrier or other similar roadside hazard, and cooperates with the barrier or hazard to absorb energy when a vehicle hits the terminal itself. (See, e.g., '003 Patent at col. 1, lines 7-12.) The claimed terminal must also include an impact head, and numerous other requirements as follows [in the further language of Claim 6].

(Def.'s Prel. Inj. Hrg. Ex. 68, Pl.'s Answers to Def.'s Interrogatories at 3). KFI relies, in part, on the following language from the specification in the '003 Patent:

In one class of guardrail system, each guardrail system includes an elongated barrier and at least one energy absorbing terminal. The elongated barrier extends parallel to the roadway along the side of the roadway and ends in a terminal. The terminal cooperates with one or more components of the barrier to absorb energy when a vehicle hits the terminal itself.

(Docket Entry No. 33, Ex. A, col. 1, ln. 7-13). KFI also relies on extrinsic evidence, including the testimony of the inventor, Dr. Dean L. Sicking. Dr. Sicking testified that a person of ordinary skill in the art would understand "terminal" as used in claim 6 to include a device used to treat the end of guardrails, bridge rails, and other "roadside hazards" such as a truck or a sign.

Trinity defines "terminal" as:

A device designed to treat the end of a longitudinal barrier . . . . [A] longitudinal barrier is a safety device whose primary functions are to prevent vehicular penetration and to safely redirect an errant vehicle from a roadside hazard or median hazard. The three types of longitudinal barriers are roadside barriers, median barriers, and bridge rails . . .

(Def.'s Prel. Inj. Hrg. Ex. 70, Def.'s Answers to Pl.'s Interrogatories at 5). In support of its proposed interpretation, Trinity cites to extrinsic evidence, including the glossary of the National Cooperative Highway Research Program ("NCHRP") Report 350, (Def.'s Prel. Inj. Hrg. Ex. 11), and the testimony of Maurice Bronstad as to how a person of ordinary skill in the art would understand the claim term "terminal."

The crux of the parties' dispute is whether a "terminal" includes a device used to treat the end of a truck or work vehicle, such as the MPS 350. KFI asserts that the "MPS 350 truck mounted attenuator is a 'terminal' that forms the end of an
The '003 Patent does not define "terminal." KKI relies, in part, on the "Background of the Invention" in the '003 Patent to support the argument that a terminal includes the end of a truck or work vehicle, as opposed to a fixed barrier such as a guardrail. The relevant portion of the "Background of the Invention" Section states as follows:

This invention relates to guardrails intended to be positioned along a highway to reduce injury to the driver and passenger of vehicles that may accidentally tend to leave the highway.

In one class of guardrail system, each guardrail system includes an elongated barrier and at least one energy-absorbing terminal. The elongated barrier extends parallel to the roadway along the side of the roadway and ends in a terminal. The terminal cooperates with one or more components of the barrier to absorb energy when a vehicle hits the terminal itself.

The terminal is constructed to stop the vehicle without subjecting the occupant to excessive forces and to avoid impaling the passenger compartment of the vehicle or redirecting the vehicle in a dangerous direction or permitting the vehicle to continue in a dangerous direction at a dangerous speed when the vehicle hits the terminal itself. The barrier is designed to redirect the vehicle in a safer direction and impede its progress when the vehicle hits the barrier itself.

The terminals and barrier of the energy-absorbing guardrail are designed so that: (1) when the vehicle hits the barrier itself, the barrier is anchored by a cable or similar component with tensile strength to support the vehicle from moving excessively in a direction perpendicular to the roadway; and (2) when the vehicle hits the terminal, the cable or other support member is released to avoid pulling the barrier out of its alignment with the terminal which would prevent movement of the terminal and barrier together to absorb energy.

(Docket Entry No. 33, Ex. A, col. 1, ln. 1-30).

The applicants used the word "terminal" to refer to the end of an "elongated barrier." The applicants described an elongated barrier that is "anchored" to prevent the vehicle from moving perpendicular to the roadway. The specifications and preferred embodiments refer to "guardrails." However, the prosecution history shows that while the applicants initially limited their claims to a device used to cut a "guardrail," in February 1997, the applicants broadened their claims by changing "guardrail" to "cutable member." (Docket Entry No. 47, p. 15, ln. 8-23, p. 17, ln. 5-10). One of the embodiments shows a "concrete structure" rather than a guardrail. (Docket Entry No. 33, Ex. A, Fig. 14). The word "terminal" clearly is not limited to the end of a guardrail.

Although the '003 Patent is not limited to a guardrail, the patent does not state or suggest that a "terminal" includes the end of a truck or a work vehicle on or alongside a road. The language in the specification describes a terminal at the end of an "elongated barrier" that is itself "anchored." The applicants did not use the word "terminal" to refer to the end of a moving or moveable truck or work vehicle. A truck, or work vehicle, even when parked, is not ordinarily described as an "elongated barrier," and is not "anchored" to the roadside. Unlike guardrails and other structures that are ordinarily described as "elongated barriers," the MPS 350 may be attached to, and used by, a slowly moving truck that is at the end of, or follows behind, a group of work vehicles. The intrinsic evidence, particularly the specification in the '003 Patent, does not support the contention that the word "terminal" applies to the end of a truck or work vehicle.

The parties presented conflicting expert testimony as to the meaning of the word "terminal." Dr. Sicking, the inventor of the '003 Patent, testified that a "terminal" is "a device used to mitigate the hazard associated with the end of the barrier or another roadside obstacle and cooperate with the barrier end or the other roadside obstacle to reduce the injury and fatalities associated with ran-of-road accidents." (Docket Entry No. 42, p. 66, ln. 5-9). When asked how he "arrived at that definition," Sicking responded: "That's the definition of a terminal, as I understand it, in our industry as we -- as we, basically, laid out in the '003 patent." (Id. at 135, ln. 6-8). When asked to describe "what kinds of things are roadside obstacles," Sicking answered: "Well, you have bridge piers. You have large mass signing. You have culverts. You have -- in
the case of work zones, you have trucks, equipment, trailers. There are just a wide variety of roadside obstacles, sign supports, luminary supports." (Id. at 132, ln. 9-14).

Trinity argues that Dr. Sicking's testimony is "improper extrinsic evidence." (Docket Entry No. 59, p. 19). In Vitronics, the Federal Circuit held that the trial court erred in relying on the inventor's testimony as to claim interpretation because the patent specification and other intrinsic evidence clearly defined the term. 90 F.3d at 1583-84. The court noted that the inventor's definition was inconsistent with the specification and would have rendered one of the preferred embodiments uncovered by the patent. Id. While a court may rely on expert testimony to resolve ambiguities remaining after considering intrinsic evidence, a court may not use extrinsic evidence to contradict or vary the claim language. Id. at 1584. "Nor may the inventor's subjective intent as to claim scope, when unexpressed in the patent documents, have any effect." Id.

In Markman, the Federal Circuit found that the meaning of the disputed term was "clear" from the patent and prosecution history. 52 F.3d at 983. The court held that the district court appropriately "exercised its discretion in finding unhelpful [the expert/inventor's] testimony that he meant [the term], or that one of ordinary skill in the art would understand [the term], to mean something to the contrary, and furthermore the district court rejected the testimony as conflicting with the meaning derived from the patent and prosecution history." Id.

Dr. Sicking testified that a "terminal" could include any "roadside obstacle," including a sign, a vehicle, or a sign support. KKI's evidence limited the definition of "terminal" to roadside hazards that are "similar" to elongated barriers in critical aspects, including the aspects of being a structure, fixed in place, designed to stop and redirect impacting vehicles. To the extent that Dr. Sicking testified as to his own broader definition, his testimony is irrelevant to the inquiry. To the extent that Dr. Sicking testified as to how he interpreted the '003 Patent to use the word "terminal," as opposed to how "terminal" is generally understood by a person of ordinary skill in the art, his testimony is irrelevant to the inquiry. See Vitronics, 90 F.3d at 1584 (inventor's subjective intent may not be used to alter scope of claim); Markman, 52 F.3d at 983 (inventor and expert's testimony as to how claim should be construed based on text of patent is "legal opinion" and inappropriate extrinsic evidence in construing a claim).

Maurice Bronstad, Trinity's expert witness, testified that Trinity's definition is the "usual" definition of the word "terminal," as understood by a person skilled in the art. Bronstad testified that while he "wouldn't say [he] necessarily disagreed with [KKI's definition]." KKI's definition is not the "normal" definition because of the "roadside hazard" language. Bronstad testified that a "roadside hazard" could include anything -- a tree, an embankment, or a vehicle, to which the word "terminal" would not apply. (Docket Entry No. 47, pp. 109-111). Bronstad testified that the NCHRP Report 350 definition of "terminal" is how the term is reasonably understood by a person skilled in the art, and that Trinity used a "nearly identical" definition.

The NCHRP Report 350 was published by the Transportation Research Board in 1993 to provide "recommended procedures for evaluating the safety performance of various highway safety features." (Def.'s Prel. Inj. Hrg. Ex. 11, T00517). The Federal Highway Administration requires all roadway safety devices used on the national highway system to meet performance standards set out in the NCHRP Report 350. (Docket Entry No. 47, pp. 150-51). Dr. Sicking was an author of the report. (Def.'s Prel. Inj. Hrg. Ex. 11, T00515; Docket Entry No. 42, p. 135, ln. 17-19). The glossary of the NCHRP 350 includes the following definitions:

- Terminal A device designed to treat the end of a longitudinal barrier. A terminal may function by (a) decelerating a vehicle to a safe stop within a relatively short distance, (b) permitting controlled penetration of the vehicle behind the device, (c) containing and redirecting the vehicle, or (d) a combination of a, b, and c.

- Longitudinal Barrier A device whose primary functions are to prevent vehicular penetration and to safely redirect an errant vehicle away from a roadside or median hazard. The three types of longitudinal barriers are roadside barriers, median barriers, and bridge rails.

- Truck-Mounted Attenuator (TMA) An energy-absorbing device attached to the rear of a truck or utility vehicle. A TMA is designed to provide a controlled stop of a vehicle impacting the rear of the truck.

(Def.'s Prel. Inj. Hrg. Ex. 11, T00695-96).
The NCHRP Report 350 defines a "terminal" as attached to a "longitudinal barrier," which includes "roadside barriers, median barriers, and bridge rails." This is consistent with the '003 Patent's use of "terminal" to refer to the end of a "guardrail" or an "elongated barrier" that extends parallel to the roadway along the side of the roadway and is "anchored" to the roadway to prevent perpendicular movement of a vehicle leaving the roadway. The NCHRP Report 350 distinguishes between a "longitudinal barrier" and a "roadside hazard." A longitudinal barrier's "primary functions are to prevent vehicular penetration and to safely redirect an errant vehicle away from a roadside or median hazard." The longitudinal barrier keeps the vehicle from hitting the roadside hazard; the hazard itself is not the barrier. The NCHRP Report 350 discusses truck mounted attenuators in a separate section from the section on "terminals and crash cushions." (Id. at T00520-21). The glossary defines a "truck mounted attenuator" as a "device attached to the rear of a truck or utility vehicle . . . designed to provide a controlled stop of a vehicle impacting the rear of the truck." The glossary does not include a "truck" in the definition of "terminal" or "longitudinal barrier." Devices attached to the ends of longitudinal barriers--"terminals"--are different from those devices attached to trucks and working vehicles. The NCHRP Report 350 provides support for Trinity's position that a "terminal" refers to the device at the end of a "longitudinal barrier," not to the back of a truck or work vehicle.

Trinity argues that this court should adopt the NCHRP Report 350 definition as "the ordinary and accustomed meaning of the word 'terminal' in the roadside safety device field." (Docket Entry No. 59, p. 19). In Vitronics, the court stated that "although technical treatises and dictionaries fall within the category of extrinsic evidence, as they do not form a part of an integrated patent document, they are worthy of special note." 90 F.3d at 1584 n.6. The court described treatises and dictionaries as "more objective and reliable guides" than expert testimony. Id. at 1585. "Unlike expert testimony, these sources are accessible to the public in advance of litigation. They are to be preferred over opinion testimony, whether by an attorney or artisan in the field of technology to which the patent is directed." Id.

The intrinsic evidence, particularly the specification, suggests that a "terminal" is attached to an elongated barrier that is anchored to prevent the impacting vehicle's perpendicular movement and does not include a truck or work vehicle. Bronstad testified that the term "terminal" would not ordinarily be understood to describe the end of a truck. The MPS Report 350 definition supports this testimony. The patent language does not suggest that the applicants intended "terminal" to include the end of a truck or work vehicle. See Markman, 52 F.3d at 980 ("[A] patentee is free to be his own lexicographer. . . . The caveat is that any special definition given to a word must be clearly defined in the specification.") (internal citation omitted). No special definition is provided here. However, this court notes that even if KKI's proposed definition was adopted, a truck or work vehicle is not "similar" to an "elongated barrier."

The parties do not dispute that the TRACC contains a "terminal." The issue is whether the MPS 350 also contains a "terminal." The MPS 350 truck-mounted attenuator is attached to a truck, not to a roadside barrier, median barrier, or bridge rail. Unlike longitudinal barriers such as a guardrail, median barrier, or a bridge rail, a truck or work vehicle is not anchored to the roadside. A truck or work vehicle is not designed to redirect and stop an impacting vehicle. A truck or work vehicle is a roadside hazard, not a barrier designed to prevent an impact with a hazard. The MPS 350 may be used not only when the truck to which it is attached is stationary, but also when the truck is traveling slowly behind a group of vehicles. None of the traditional longitudinal barriers, such as a guardrail or bridge rail, is attached to a moving object.

This court finds that KKI has failed to make a clear showing of a reasonable likelihood of success in proving that the MPS 350 includes a "terminal."

3. Terminal Portion

This term is used in asserted Claim 1 in reference to "the driven lug engaging a terminal portion of the appendage during rotation of the handle means about the axis of rotation." 086 patent, col. 6, 11. 61-64. In relevant part, "terminal" means "of or relating to an end, extremity, boundary, or terminus." Webster's Third, Gerdes Ex. 241. The ordinary definition of "portion" is "a part of a whole." Webster's Third, Gerdes Ex. 237. Thus, the ordinary meaning of "terminal portion" is the part of the whole at the end, extremity, or boundary of the whole.

Again, Gerdes contends that the court should restrict the definition of this term based on the depiction in Figure 2.
Specifically, Gerdes states that in that drawing one can see that the lug contacts the lower unattached portion of the appendage, including the unattached end point of the appendage. Thus, Gerdes urges that the "terminal portion" should specifically include the unattached end point of the appendage. As with the term "lug," however, Gerdes provides the court with no reason to import such a limitation from the specification into the terms of the claims themselves. See Texas Digital Systems, Inc., 308 F.3d at 1204 (finding that the presumption that a term is given its ordinary meaning is only overcome if in the specification the patentee "clearly set[s] forth an explicit definition of the term different from its ordinary meaning"). Gerdes also attempts to use the prosecution history to support its argument that "terminal portion" should be given special meaning, but admits that the remarks to the amendment provide no reasoning for why the term was added to the claim. Thus the court is unable to derive anything about the meaning of the term from this amendment.

As stated above, absent an explicit reason to do so the court cannot read into the claim terms a limitation found only in the preferred embodiment of the patent. Advanced Cardiovascular Sys., Inc., 261 F.3d at 1338-39. Therefore, because the court finds no such explicit directions in the specification of the 086 patent to deviate from the ordinary definition of the term "terminal portion," the term, when used in Claim 1, must be used according to its ordinary meaning. Thus, the "terminal portion" means the part of the appendage at the end, extremity, or boundary of the appendage.

6. "Testing"

According to the method taught by Claim 1, the bringing step is followed by "testing said corresponding contact surfaces for the existence of correct alignment and electrical contact between said corresponding contact surfaces." Col. 9, Ins. 67-68; Col. 10, Ins. 1-2. The parties dispute, what is tested, when it is tested, and how it is tested.

The issue of what is tested -- "corresponding contact surfaces" -- has been resolved above: more than one but not necessarily all contact surfaces. One skilled in the art would be able to practice this method to determine electrical contact and correct alignment without testing each and every surface. The language does not compel the limitation that all surfaces be tested. See also Col. 6, Ins. 57-62 ("To test whether or not the electric contact has been well established, it suffices to read the content of the first address.").

5 As to when testing begins, Thomson again argues that under § 112 P 6, "testing" is too broad and indefinite and must be limited to the test set forth in the specification -- i.e., a continuous test. That reading, however, is inconsistent with the terms of Claim 5 (dependent from Claim 4, which is, in turn, dependent from Claim 1), which teaches steps a-c practiced in sequence. As Claim 5 is narrower than Claim 1, limiting Claim 1 to a continuous test would conflict with the terms of Claim 5. The Court is not persuaded that a continuous testing limitation must be imported to save Claim 1, step(b) from invalidity. Cf. Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1248-49 (Fed. Cir. 1998) ("Without any claim term that is susceptible of clarification by the written description, there is no legitimate way to narrow the property right.").

The substantial dispute between the parties concerns how testing occurs. To resolve this dispute, two other terms must be construed.

The test in step (b) tests for "the existence of correct alignment and electrical contact between said corresponding contact surfaces." The parties appear to agree that the test is at least to determine the presence of two conditions vis-a-vis the corresponding contact surfaces: (1) correct alignment; and (2) electrical contact. According to the Commission, "the ALJ construed the testing limitation of step (b) to require a test that is expressly for the purpose of determining proper alignment and correct electrical contact. . . . We agree with and adopt the ALJ's construction [not challenged]." ITC at 23.

The test is conjunctive, and the implication is that if either condition is not met, the test fails. However, testing is followed by the "displacing" step (c) "if said testing determines non-alignment and non-existence of correct electrical contact." (emphasis added). Innovation urges the Court to convert "and" into "or", as one skilled in the art would do. See Tr. (June 30,
1998, p.m.) at 53-54 (Dr. Kuc). Otherwise, steps (b) and (c), read literally, leave a gap. The method would be practiced by bringing the contact surfaces into contacting relationship, testing the surfaces, and no further action taking place, even if the test revealed the non-existence of correct electric contact -- the very purpose of the patented method -- so long as the other condition (correct alignment) was present. The same result would follow from the inverse situation.

As anomalous as this reading may seem, Thomson argues that Innovation is stuck with Moreno's poor drafting. Moreover, that drafting was the product of an agreement made with the Patent and Trademark Office ("PTO"). The term "non-alignment and non-existence of electrical contact" was drafted in response to the examiner's indefiniteness objection. The examiner wrote:

Applicant's attorney provisionally agreed [sic] amending Claim 19 [issued Claim 1] to include limitation of alignment in Claim 19, paragraph b after "correct" and in Paragraph C to include "non-alignment and" after "determines" and in penultimate line to recite "alignment and". The remaining claims will be amended as per attached draft. The specification will be amended accordingly.

464 Patent Prosecution History [hereafter "Prosecution History"] at II0150 (Tab 14) (emphasis added). Neither the disclosure of the invention, nor its preferred embodiment in the specification requires a positive test for non-alignment and non-existence of electrical contact. See, e.g., Col. 2, lns. 18-24; Col. 6, lns. 57-62.

Where the literal language of a claim, read in isolation, leads to an absurd result -- a method that would patently fail to achieve its purpose; where the file wrapper indicates that the specification would reflect the bargain made with the PTO; and where the specification suggests that displacing occurs in the absence of either correct alignment or electrical contact, the Court is persuaded that one skilled in the art would read "non-alignment and non-existence of electric contact" to mean "non-alignment or non-existence of electric contact." See Renishaw, 158 F.3d at 1250 ("Ultimately, the interpretation to be given a term can only be determined and confirmed with a full understanding of what the inventor actually invented and intended to envelop with the claim.").

In sum, the term "testing" in Claim 1, step (b) comprises a single, express test for correct alignment and electrical contact. The displacing step, Claim 1, step (c), is triggered if the test in step (b) fails because one or both conditions are not satisfied.

3. "a textile material"

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiff's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>a textile material</td>
<td>A woven, knitted, nonwoven or extruded material.</td>
<td>A single protective element formed of a woven synthetic material such as polypropylene formed in a monofilament and woven into a geotextile.</td>
</tr>
</tbody>
</table>

At the hearing, Defendants maintained that the parties' proposed constructions are "not too far apart." A comparison of the parties' proposals, however, tends to show otherwise. In the end, the Court concludes that Plaintiff's proposed construction is proper. Patent '085's summary of the invention states that the "invention contemplates the use of a flexible barrier of woven synthetic textile." Patent '085, col. 1, Ins. 65-66. The specification later discloses figure 7 as illustrating a preferred construction of the "textile material of this invention" and states that a "suitable material" for use as the textile material "is polypropylene formed in a monofilament and woven into a geotextile." Patent '085, col. 5, Ins. 19-22. That very same paragraph goes on to state that "[w]hile a woven material is shown [in figure 7], the material may be knitted, nonwoven or extruded with apertures formed therein." Patent '085, col. 5, Ins. 25-30. It is clear that Defendants' proposed construction selectively excludes this latter portion of the paragraph and, thus, improperly confines the claim language to a narrow version of the preferred embodiment.

The Federal Circuit consistently emphasizes that courts may not limit a claim to a particular embodiment appearing in the
written description when the claim language is broader than the embodiment, i.e. courts may not import limitations from the specification into the claim. See Varco, 436 F.3d at 1373 ("this court will not at any time import limitations from the specification into the claims"); Resonate Inc. v. Alteon Websystems. Inc., 338 F.3d 1360, 1364-65 (Fed. Cir. 2003) ("a particular embodiment appearing in the written description may not be read into a claim when the claim language is broader than the embodiment"). In this case, the term "textile material" encompasses a broader meaning than that which is set forth by Defendants. The Court concludes that Plaintiff's interpretation is more accurate and, thus, construes "a textile material" as meaning "a woven, knitted, nonwoven or extruded material."

C. "Textured"

The parties agree that "textured" is the opposite of "non-textured." Accordingly, based on the Court's determination that "non-textured" means "smooth," "textured" means "not smooth."

2. The Retrieving Steps

"Retrieving one of the sets [of] data from the memory (86) representing one of the fuel delivery limit curves when the cruise control (44) is engaged;"

"Retrieving the other set of data from the memory (86) representing the other fuel delivery limit curve when the cruise control (44) is not engaged"

The parties propose very different interpretations of the retrieving steps of the '597 patent. Detroit Diesel contends that the retrieving steps require the retrieval of one set of data representing a fuel delivery limit curve if the cruise control is engaged, and the retrieval of a different set of data representing a different fuel delivery limit curve if the cruise control is not engaged. Detroit Diesel bases its interpretation on the plain language of the claim and on the dictionary definition of "other." Detroit Diesel also refers the court to what it deems an admission by Caterpillar to the European Patent Office during prosecution of the same claim with that office that the claim is invalid unless the retrieving steps are limited to mutually exclusively retrieving one set of data or the other set of data depending on whether the cruise control is engaged. In response to an objection from the EPO, Caterpillar inserted a reference to prior art WO-A-8403911 (the Thompson Patent European counterpart), explaining in its letter to the EPO presenting the amended application that the reference "does not suggest using a high horse power curve during cruise control engagement and a lesser horsepower curve simply because the cruise control is engaged." Caterpillar amended the claim to explain that WO-A-8403911 "does disclose limiting fuel supply to a to a lower range of values … when cruise control is off than when it is on, even though the limitation to using a lower range of values is not primarily determined by whether or not the cruise control is engaged or disengaged." See Exh. F to Detroit Diesel's Motion.

Caterpillar, on the other hand, contends that when properly interpreted in their open format, the retrieving steps are not limited in the manner Detroit Diesel proposes. Caterpillar claims that the first retrieving step can only be interpreted to require retrieval of at least one set of data, representing one or more fuel delivery limit curves, when the cruise control is engaged. Caterpillar explains that the lower limit curves (which would, under Detroit Diesel's interpretation, be available only when cruise control is not engaged) may also limit the command signal if cruise control is engaged, as shown in the preferred embodiment, in which the additional power is not retrieved unless power above the lower limit curve is needed to maintain the cruise set speed:

Higher rated rack limits, and thus higher engine output torque and horsepower levels, are made available when: (1) the cruise control is engaged; (2) the cruise control set speed is greater than a minimum predetermined speed; and (3) the vehicle speed is less than the cruise control set speed plus a predetermined value.
If any of the questions posed by the blocks 130, 132, or 134 [of Figure 3] is answered in the negative, then it has been determined that the increased rack limits represented by the torque curves 120A, 122A and respective horsepower curves 120B and 122B are not to be used.

'597 Patent, Col. 6, lines 23-29 and 62-66. Caterpillar thus concludes that the specification itself contradicts Detroit Diesel's interpretation because it describes a situation where cruise control is engaged but the upper limit curve is not retrieved. The preferred embodiment thus evaluates conditions other than whether the cruise control is engaged before selecting a particular set of data. Because the claim is written in an open format, Caterpillar argues, it will read on devices that include additional elements not referenced in the claim.

According to Caterpillar, the second retrieving step must be read to allow the retrieval of more than one set of data from memory when cruise control is not engaged, and cannot be read as restricting retrieval of the second (lower) fuel delivery limit curve to when the cruise control is not engaged. Claiming to construe the patent practically and in accordance with its purposes, Caterpillar asserts that the second retrieving step may properly be construed to require retrieval of the lower fuel delivery limit curve where power is demanded through the throttle (where by definition the cruise control is not engaged), and to "preclude throttle retrieval of the higher curve in other circumstances."

Caterpillar objects to Detroit Diesel's reliance on the EPO documents, claiming they are presented out of context and in edited form, and are not legal admissions by Caterpillar, and do not support Detroit Diesel's arguments. The correspondence, Caterpillar claims, merely shows its disagreement with the EPO about whether the Thompson Patent European counterpart taught use of the cruise control as a determining step for accessing additional power.

Lastly, Caterpillar argues that the court cannot accept Detroit Diesel's interpretation of Claim 1 because it would mean that "the fuel delivery limit curves in Figures 2A and 2B are mutually exclusive," which in turn would make Claim 3 11 of the patent directly contradicted by Claim 1 and rendered meaningless. Detroit Diesel's reply seems to accept Caterpillar's assertion that its interpretation of Claim 1 would make Claim 3 contradicted by Claim 1 and rendered meaningless, but points out that claim differentiation 12 is a "guide, not a rigid rule." See Autogiro, 384 F.2d at 404.

--- Footnotes ---

11 Claim 3 of the '597 patent provides: "3. The method of claim 1, including the further steps of determining whether the speed of the vehicle is less than the set speed plus a predetermined value and retrieving at least a portion of the other set of data from the memory (86) when the vehicle speed is not less than the set speed plus the predetermined value."

12 The doctrine of claim differentiation is a canon of claim construction which holds that when a patent contains both broad and narrow claims, the additional limitation of the narrow claim should not be read into the broad claim. The doctrine embodies the common sense notion that ordinarily language of one claim should not be so interpreted as to make another claim, such as a claim dependent on the first claim, identical in scope. Motorola, Inc. v. Interdigital Technology Corp., 930 F. Supp. 952, 965 (D.Del. 1996) (quotations and citations omitted).

--- End Footnotes ---

Detroit Diesel's reply brief makes two points relevant to construction of the retrieving steps. Detroit Diesel criticizes Caterpillar's interpretation of the retrieving steps as doing "violence to language as a tool for communication" by effectively eliminating the determining step altogether since, according to Caterpillar, the same sets of data may be retrieved without regard to whether the cruise control is engaged. Detroit Diesel also presents the deposition testimony of the first named inventor of the '597 patent, Michael Moncelle, who explains:

Q. So the first and second retrieving steps are mutually exclusive of one another depending on the answer to the determining step; is that accurate?

A. (Mr. Moncelle): Yes, they are mutually exclusive. You choose one or the other.
Moncelle Dep. at 31. In his affidavit, Mr. Moncelle explains that the steps are mutually exclusive in that one or the other sets of data is retrieved (engine fuel delivery necessarily is restricted at any point in time by one of the limit curves), but that this does not mean that the higher fuel delivery curve is the only accessible curve during cruise control engagement. Moncelle Aff., PP 10-11.

After examining the claim and the entire specification and considering the parties' arguments, the court agrees with Detroit Diesel's construction of the retrieving steps of the '597 patent. The claim states that one of the sets of data representing one of the fuel delivery limit curves is retrieved when cruise control is engaged, and the other set of data representing the other fuel delivery limit curve is retrieved when the cruise control is not engaged. As Detroit Diesel argues, the claim allows for the cruise control to be in one of two states (engaged or not engaged), and one of two different sets of data is retrieved depending on whether the cruise control is engaged or not engaged. By its own words, the claim sets up two mutually exclusive possible situations.

The court cannot reconcile Caterpillar's urged interpretation with the language of the claim. Caterpillar argues that because the claim is written using "comprising," i.e. in open format, limitations that are not present in the claim's language cannot be read into the claim. While it is true that a claim written in open format does not exclude additional unrecited elements, see Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1271-1272 (Fed. Cir. 1986), Caterpillar's interpretation is not based on additional unrecited elements. Caterpillar argues for an interpretation of the retrieving steps in which neither step is limited even to the language set forth in the step. The claim's words must be given their ordinary and accustomed meaning unless it appears that the inventor used them differently. ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579 (Fed. Cir. 1988); Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759 (Fed. Cir. 1984). The first retrieving step provides for retrieval of one set of data when the cruise control is engaged, and the second step provides for retrieval of the other set when the cruise control is not engaged. Caterpillar now argues that either set may be retrieved when the cruise control is engaged, and that when the cruise control is not engaged, the first set may nonetheless be retrieved, such as during power take-off. Caterpillar's asserted construction of Claim 1 may make sense in a vacuum, and even jibe with the purposes of the patent (making additional power available when necessary to maintain the set speed), but it finds no support in the claim's language. 13

13 The court does not rely on the EPO documents in reaching this conclusion, and determination of their meaning and status as "admissions" is not necessary.

Caterpillar's reference to portions of the preferred embodiment to support its interpretation is likewise unconvincing. The portion of the preferred embodiment Caterpillar references supports its assertion that in the preferred embodiment additional power is not retrieved unless power above the lower limit curve is needed to maintain the cruise set speed, but the portions Caterpillar cites recite additional steps (corresponding to blocks 132, 134, and 136 of Figure 3) that are not contained in Claim 1, but rather can be seen in the language of Claims 2 and 3 of the patent.

Lastly, Caterpillar's claim differentiation argument does not alter the court's conclusion. Caterpillar contends that Claim 1 cannot be interpreted in the manner urged by Detroit Diesel--"that the fuel delivery limit curves in Figures 2A and 2B are mutually exclusive"--because it would make Claim 3 of the patent directly contradict Claim 1. Caterpillar has not, however, explained how or why Detroit Diesel's interpretation would render Claim 3 contradicted by Claim 1 and "meaningless", and the answer is not obvious to the court.

4113

Gathering parts-related information for one or more parts within the plurality of parts which meets the customer's requirements

Defendants urge the Court to construe this term as "gathering information about parts that meet the customer's requirements from the electronically specified part information." Defendants argue this construction is necessary to define what is meant
by "the plurality of parts," which refers to the parts that were defined in element (b) of claim 1 with the language "electronically specifying information identifying a plurality of parts." Defendants' construction requires multiple parts to meet the customer's requirements; the claim language requires one or more parts. Defendants construction is also susceptible to being misunderstood. Orion seems to understand the construction to mean that the information is gathered from the electronically specified part information. Defendants contend that the plurality of parts are those that were electronically specified.

The Court agrees with Orion that this phrase does not require construction. In some contexts, "the plurality of parts" or similar terms may be confusing to a lay jury. Here, the antecedent "plurality of parts" is identified in the previous step. Given the close proximity of the phrases, it is highly unlikely to be confusing.

4114

9. "the polygon further comprises a first wall having a concave shape and a second wall having a convex shape"

This phrase is found in claims 58-75 of the '037 patent, and in claims 14, and 19-25 of the '255 patent. See Joint Statement, '037 and '255 Patents. Plaintiffs contend that "the polygon further comprises a first wall having a concave shape and a second wall having a convex shape" should be construed to mean "the polygon having a first wall with an apex directed toward the interior of the polygon and a second wall, also with an apex, directed away from the interior of the polygon." Defendants and the intervenor contend that the phrase should be construed to mean "the first wall of the polygon connecting the pair of side walls consists of a concave shape and the second wall of the polygon connecting the pair of side walls consists of a convex shape."

Preliminarily, the central dispute here surrounds defendants' use of the phrase "consists of" in its proposed construction. Plaintiffs contend that the phrase improperly limits the claim language at issue to polygons with first and second walls consisting only of concave and convex shapes, whereas the intrinsic history demonstrates that the claim language at issue actually covers polygons with first and second walls that can include additional elements aside from concave and convex shapes. Defendants disagree, arguing that the intrinsic history cannot support plaintiffs' overly broad construction.

Beginning with the claim language, it is true that the claim language uses only the terms concave and convex, and might appear to limit the shapes of the polygons to such at first glance. See, e.g., Joint Statement, '037 Patent at 18:11-13. However, as plaintiffs point out, the specification and the figures all indicate that the side walls of the longitudinal portions at issue can include shapes other than just concave and convex. See, e.g., id. at 8:42-49. While the shapes claimed must include concave and convex elements, they are not limited to sole inclusion of just those elements.

This is apparent in figure 5 of the patent, for example, which discloses a polygon that includes a straight portion of the otherwise concave and convex side walls. See Joint Statement, '037 Patent at 9:2-5 ("alternatively, more than three segments can be used to define concave-shaped wall 50 and/or convex-shaped wall 60").

Moreover, the court is not persuaded by defendants' and the intervenor's contrary arguments. First, while defendants rely on the prosecution history for support of their arguments, the evidence they rely on does not, in the court's view, require that the claimed polygon shape be expressly limited to convex and concave walls connecting pairs of side walls, as defendants and the intervenor propose. Second, defendants' and the intervenor's primary objection appears to be that, if plaintiffs' proposed construction is adopted, the claims at issue will cover polygon shapes consisting of upper and lower walls that are 'undulating' -- i.e., comprised of wave-like alternating apexes -- on the premise that each wall's 'undulation' includes both concave and convex elements. See Defs. Opp. Br. at 29:25-27. In defendants' and the intervenor's view, this would fly in the face of the intrinsic evidence, since the claims limit the first wall to a single "concave" shape and the second wall to a single "convex" shape. This argument is not particularly compelling, however, for it is not immediately apparent to the court how plaintiffs' proposed construction -- which expressly requires "an apex" directed toward the interior of the polygon, and a second apex directed away from the interior of the polygon -- lends itself to the conclusion defendants' suggest in view of the presence of multiple apexes depicted in defendants' depicted "undulating" shape. At any rate, defendants' issue is more appropriate for the summary judgment or trial stage of litigation, and ultimately, it is the province of the jury to determine whether an accused device reads upon a claim limitation, as properly construed.
For these reasons, the court hereby adopts plaintiffs' proposed construction and construes "the polygon further comprises a first wall having a concave shape and a second wall having a convex shape" as: "the polygon having a first wall with an apex directed toward the interior of the polygon and a second wall, also with an apex, directed away from the interior of the polygon." 5

5 Defendants have also argued that claims 17 and 18 of the '255 Patent should be found void for indefiniteness, an argument that plaintiffs only summarily deal with. The court would prefer the benefit of more complete briefing on the matter before rendering a determination. Accordingly, the court defers consideration of this issue until the parties are able to submit more complete arguments at the dispositive motion juncture.

4. "The wall has a thickness of greater than 0.018 inch"

The next claim term for which the parties dispute the proper construction is "the wall has a thickness of greater than 0.018 inch," which is found in claims 5 and 11 of the '668 patent. The parties' competing constructions of this claim term are shown in the following chart:

<table>
<thead>
<tr>
<th>THE '668 PATENT</th>

<tr>
<td>d. The wall has a thickness of greater than 0.018 inch (In claims 5 and 11)</td>
</tr>
</tbody>
</table>

a. Arguments of the parties

Rivard's argument in support of its construction of this claim term is comparatively concise. Rivard contends that the pertinent claims recite thickness of the needle "wall" using the singular form, while claims 4 and 11 of the '196 patent, in contrast, specify "combined" thickness of the needle "sidewalls." This difference in language leads Rivard to the conclusion that only one "wall" is at issue in claims 5 and 11 of the '668 patent. Rivard also points out that the Detailed Description refers to "inner" and "outer" sidewalls, suggesting that these inner and outer surfaces would establish a thickness that is measured on one side of the lumen, not both. Thus, in Rivard's view, the claims and specification establish that the thickness of the wall is measured on one side of the lumen, not by adding together the thickness of the wall on both sides of the lumen.

Ideal contends that this claim term is clear and unambiguous, and that its meaning is readily apparent within the context of the '668 patent. Ideal also argues that the prosecution history establishes that the examiner and the patentee understood this claim phrase to have its customary meaning, and that the scope of the term was not expressly limited during patent prosecution. Ideal argues that Rivard's proposed construction improperly narrows and rewrites the claim language by reference to the '196 patent. Ideal points out that the pertinent claims of the '668 patent, and the independent claims from which they depend, refer only to "the wall" or "at least one wall." Consequently, Ideal argues that the plain language of the claim is not limited to only one wall having a thickness of 0.018 inch, because the language of the related independent claims states "at least one wall." In light of this language, Ideal argues that restricting the claim term to one wall being more than 0.018 inch thick is not permitted. Ideal also points out that none of the phrases that Rivard uses to define this claim term can be found anywhere in the prosecution history. If any construction is required, Ideal contends that its construction of the term as "needle wall thickness greater than 0.018 inch" is well supported by the claim language and intrinsic evidence.

b. Analysis
i. Relationship to independent claims. In construing this claim term, the court finds that it must not only begin with the words of the claim term presently at issue, see Nystrom, 424 F.3d at 1142 (courts must "begin [their] claim construction analysis with the words of the claim"), but with the words of the independent claim from which depend the dependent claims in which that claim term is found. This is so, because dependent claims are to be construed to incorporate by reference all the limitations of the independent claim from which they depend. See, e.g., Robotic Vision Sys., Inc. v. View Eng'g, Inc., 189 F.3d 1370, 1376 (Fed. Cir. 1999) ("Claims 11 and 12 are dependent claims of claim 1 and are to be construed to incorporate by reference all the limitations of claim 1," citing 35 U.S.C. § 112 (1994)).

Dependent claim 5, in which the claim term at issue is found, depends from independent claim 1 (or independent claim 2, which is not at issue in this litigation), while dependent claim 11, in which the claim term at issue is also found, depends from independent claim 7 (or independent claim 8, which also is not at issue in this litigation). Claim 1 claims, inter alia, "an injection means comprising a tubular needle defined by at least one wall forming the tube. . . . " Dependent claim 5 then claims "[t]he method of claim 1 or 2 wherein the wall has a thickness of greater than 0.018 inch." Similarly, claim 7 claims, inter alia, a "needle [that] has at least one wall. . . . " Dependent claim 11 then claims "[t]he method of claim 7 or 8 wherein the wall has a thickness of greater than 0.018 inch." The Federal Circuit Court of Appeals has explained that "[t]he phrase 'at least one' in patent claims typically is construed to mean 'one or more.'" Biagro Western Sales, Inc., 423 F.3d at 1304. Thus, the pertinent independent claims claim a needle with "one or more" walls. Logic suggests that "the wall" referred to in the dependent claims is each and every one of the walls comprising "at least one wall" of the needle claimed in the independent claims. Consequently, the thickness of "the wall" referred to in the dependent claims is the thickness of each and every one of the walls comprising "at least one wall" of the needle.

ii. Other intrinsic evidence. Other intrinsic evidence suggests the correctness of this construction. In reference to Figure 1, which "schematically illustrates a needle assembly," the Detailed Description states that the needle cannula, inter alia, "has a sidewall 17 with an outer sidewall 17A and inner sidewall 17B theretwixt having a lumen 18 extending therethrough defining a longitudinal axis." The '668 patent, Detailed Description, Col. 4, ll. 20-22. Rivard is correct that Figure 1 to the '668 patent does not show numbers 17A and 17B, but Figure 1 to the '196 patent, which is otherwise identical, does show numbers 17A and 17B near the distal end 16 of the needle cannula. Figure 1 illustrates a cylindrical tubular needle cannula, which has one and only one, and therefore "at least one," sidewall forming the tube. Indeed, the description of Figure 2 10 in the Detailed Description explains that, "[p]referably, the needle cannula of the present invention has a circular cross-section," suggesting a cylindrical tubular needle. The '668 patent, Detailed Description, Col. 4, ll. 59-61. The thickness of this sidewall is necessarily the distance between the inner sidewall 17B and the outer sidewall 17A. Even in the absence of numbers 17A and 17B, the same conclusion could be drawn from Figure 2, as shown in the '668 patent, which illustrates the sidewall 17, and the companion description in the '668 patent, which explains that, for a 16 gauge embodiment, "the sidewall 17 has a thickness greater than 0.46 mm (0.018 inch), preferably a thickness of 0.64 mm (0.025 inches)." Id., Col. 4, ll. 55-57. As illustrated, the "thickness" of sidewall 17 is the distance from the inner sidewall, that is, the wall of the lumen 18, to the outer sidewall of the needle cannula. It is equally clear that, if the needle cannula were not a cylindrical tube, and could, therefore, have more than one sidewall, the thickness of each sidewall would still be the distance between the inner sidewall 17B, that is, the wall of the lumen 18, and the outer sidewall 17A for each such sidewall. No other reference to the thickness of the sidewall elsewhere in the Detailed Description appears to the court to suggest any other manner for measuring the "thickness" of the one or more sidewalls of the needle cannula.

9 Figure 1, as shown in the '196 patent, is found in this opinion at page 10.

10 Figure 2 is found in this opinion at page 11.

Ideal appears to argue, however, that the thickness of the wall necessarily refers to the combined thickness of all sidewalls, when Ideal argues that, because the language of the related independent claims states "at least one wall," restricting the claim term to one wall being more than 0.018 inch thick is not permitted. The court does not find such an argument persuasive, however.
Such a construction would make the claim term "the wall has a thickness of greater than 0.018 inch" in claims 5 and 11 of the '668 patent synonymous with the quite different language in claims 3 and 10 of the '196 patent, which claim "the sidewalls flanking the lumen has [sic] a combined thickness of greater than 0.018 inch." One of the few differences between the specification of the '668 patent and the specification of the '196 patent is precisely in the description of sidewall thickness. The Summary of the Invention in the '668 patent states, "the sidewall has a thickness greater than 0.46 mm," and twice states, "the wall ha[s] a thickness of greater than 0.018 inch." The '668 patent, Col. 2, ll. 18, 32-33, 61-62. The comparable portions of the Summary of the Invention in the '196 patent, however, state "the two opposed sidewalls flanking the lumen have a combined thickness greater than 0.46 mm," and "the two opposed sidewalls flanking the inside diameter have a combined thickness greater than 0.018 inch." The '196 patent, Col. 2, ll. 18-19, 33-35, 62-64. Similarly, the Detailed Description in the '668 patent describes the 16 gauge embodiment of the claimed needle as a needle in which "the sidewall 17 has a thickness greater than 0.46 mm (0.018 inch), and preferably a thickness of 0.64 mm (0.025 inch)," the '668 patent, Col. 4, ll. 55-57, while the comparable portion of the Detailed Description of the '196 patent describes the 16 gauge embodiment of the claimed needle as a needle in which "the sidewalls 17 flanking (opposite each other) the lumen 18 have a combined thickness which is greater than 0.46 mm (0.018 inch), preferably a combined thickness of 0.64 mm (0.025 inch)." The '196 patent, Col. 4, ll. 56-59.

The court concludes that the quite different language in the two patents means different things. For the reasons stated above, reading the dependent claims in the '668 patent in light of the independent claims from which they depend, the language of the '668 patent unambiguously refers to the thickness of "the sidewall," meaning "each and every sidewall," not to the "combined thickness" of "the sidewalls flanking the lumen." Just as clearly, the '196 patent refers to "combined thickness" of "the sidewalls flanking the lumen."

Ideal might, nevertheless, argue that the Detailed Description supports its interpretation by pointing out that it describes the "outer diameter" as the sum of the "lumen diameter" and the "sidewall thickness," not as the sum of the "lumen diameter" and twice the "sidewall thickness," as would be the case if the "thickness greater than 0.018 inch" were meant to refer to the thickness of each and every sidewall, rather than to the combined thickness of all sidewalls. Specifically, the Detailed Description of the '668 patent explains how the "outer diameter" is derived, as follows:

In the case of the 16 gauge embodiment of the needle of the present invention, the sidewall 17 has a thickness greater than 0.46 mm (0.018 inch), preferably a thickness of 0.64 mm (0.025 inch) and the diameter of the lumen 18 is about 1.19 mm (0.047 inch). Thus, the outer diameter of needle 12 is about 1.8 mm (0.072 inch) [i.e., 0.64 mm (0.025 inch) + 1.19 mm (0.047 inch) = 1.83 mm (0.072 inch)].

The '668 patent, Detailed Description, Col. 4, ll. 54-59. The short answer to this argument is that the quoted portion of the Detailed Description contains an error, where it is otherwise clear from the claims and specification of the '668 patent that the "thickness of the sidewall" means the thickness of each and every sidewall, so that "outer diameter" should have been the sum of the "lumen diameter" and the sum of the combined thickness of the sidewalls on opposite sides of the lumen. Indeed, the Detailed Description of the '196 patent derives the same "outer diameter" for the claimed needle as the '668 patent, but based on the sum of the "lumen diameter" and the "combined thickness of the sidewalls on opposite sides of the lumen." See the '196 patent, Col. 4, ll. 55-61.

The upshot of this analysis of the differences in language between the two patents is that the sidewalls of the needle claimed in the '668 patent are twice as thick as the sidewalls of the needle claimed in the '196 patent. Although this difference may be an unintentional mistake of the patentee, it is nevertheless the result of the unambiguous language of the two patents, and hence, not a matter open to other construction.

iii. The court's construction. Thus, in light of the analysis of the proper construction of the claim term "the wall has a thickness of greater than 0.018 inch," found in claims 5 and 11 of the '668 patent, the court construes that term to mean the following: "Each and every one of the one or more sidewalls of the needle cannula has a thickness, measured from the inner sidewall (wall of the lumen) to the outer sidewall, of greater than 0.018 inch."
Step (c) reads: "Forming a second circumferential incision in the epidermis about 3 millimeters cranial to the first circumferential incision, thereby severing at least some of the subcutaneous fascia from the ungual crest ...." Defendant argues that Step (c) is invalid for indefiniteness in two ways.

First, Defendant asserts that the phrase "about three millimeters" provides no instruction to those skilled in the art and is thus indefinite. Defendant relies primarily on In re Oetiker, 23 U.S.P.Q.2d 1641 (Bd. Pat. App.1990) (finding indefinite the phrase "length on the order of 5 mm" to describe leg portions of a patent), and Ex parte Brummer, 12 U.S.P.Q.2d 1653, 1989 Pat. App. LEXIS 11 at *4 (Bd. Pat. App. 1989) (holding patent claims to a bicycle seat indefinite because the seat's measurements were based on a percentage of the rider's height and weight, reasoning "the same bicycle might fall within this language ... when ridden by a rider or one combination of weight and build, but not when ridden by a rider of another"). Plaintiff, pointing to the specification, argues that this terminology has a clear meaning. The specification explains: "The position of the second incision 3 millimeters cranial of the first incision is based upon the average size of the household cat. For smaller animals the distance will be smaller; and for larger animals the distance will be larger." Id.

As stated above, when a "word of degree" is used in a claim, a court "must determine whether the patent's specification provides some standard for measuring that degree." Datamize, LLC, 417 F.3d at 1349. In In re Oetiker, the court held "have a length of the order of 5 mm" indefinite because "there are no guidelines in appellant's specification to enable one skilled in the art to determine whether or not a given leg portion has a length of the order of 5 mm." 23 U.S.P.Q.2d 1641, 1990 Pat. App. LEXIS 37 at *15. In contrast, the '579 patent's intrinsic evidence provides at least some guidance as to the second incision's location and purpose. The specification, which is accompanied by Figure 2, explains:

The traction in the direction T causes the epithelium to release from its distal attachment and permits a second circumferential incision of the redundant epithelium approximately 3 millimeters cranial from the first incision along the line B-B. This second incision allows slightly deeper subcutaneous fascia to be moved cranially over the ungual crest as well.

The position of the second incision 3 millimeters cranial of the first incision is based upon the average size of the household cat. For smaller animals the distance will be smaller, and for larger animals the distance will be larger.

The Federal Circuit, considering similar allegations of indefiniteness, has permitted approximate measurements if the words used are "as accurate as the subject matter permits." See Orthokinetics v. Safety Travel Chairs, Inc., 806 F.2d 1565, 1576 (Fed. Cir. 1986). In Orthokinetics, the court found valid the term "so dimensioned," which the patent used to describe the measurements of a pediatric wheelchair that helped disabled children in and out of cars:

In a wheel chair having a seat portion, a front leg portion, and a rear wheel assembly, the improvement wherein said front leg portion is so dimensioned as to be insertable through the space between the doorframe of an automobile and one of the seats thereof whereby said front leg is placed in support relation to the automobile and will support the seat portion from the automobile in the course of subsequent movement of the wheel chair into the automobile .... Id. at 1568 (emphasis added). The court acknowledged that "one desiring to build and use a travel chair must measure the space between the selected automobile's doorframe and its seat and then dimension the front legs of the travel chair so they will fit in that particular space in that particular automobile," but found that "the claims were intended to cover the use of the invention with various types of automobiles" and that the phrase was "as accurate as the subject matter permits, automobiles being of various sizes." Id. at 1576. The court emphasized that "patent law does not require that all possible lengths corresponding to the spaces in hundreds of different automobiles be listed in the patent, let alone that they be listed in the claims." Id; see also Andrew Corp. v. Gabriel Elecs., 847 F.2d 819 (Fed. Cir. 1988) (finding the words "approach each other," "close to," "substantially equal to" and "closely approximate," which described the configuration of a horn reflector microwave antenna used in long distance telephone and data networks, specific enough because "it became very clear during trial ... that curves showing RPEs for horn antennas will never be identical."); Rosemount, Inc., 727 F.2d at 1547 (Fed. Cir. 1984) (finding the phrase "close proximity," which described the distance between a mounted transistor and high impedance material, acceptable because the description was "as precise as the subject matter permits").

In light of Orthokinetics, Andrew Corp. and Rosemount, the Court finds that Defendant has not proved by clear and convincing evidence the phrase "about three millimeters" is indefinite. The claim could be more definite, but in light of the
specification, Figure 2 and the variation inherent in cat sizes, the Court finds that one skilled in the art would know where to make the second incision. 8

8 At oral argument, Defendant presented an exhibit depicting five photographs of post-operative cat claws. Dr. Young testified that he believed the cat claws numbered 3 and 5 were larger-than-average; yet, when defense counsel measured the distance between the striation marks of the first and second incisions, it was less than 3 millimeters. Defendant argues that this in-court exercise demonstrates the indefiniteness of the 3 millimeter estimate and the specification's statement that "for smaller animals the distance will be smaller, and for larger animals the distance will be larger." Although the specification contains the preferred embodiment, which states that the distance between incisions correlates to the size of the cat, the Court will not narrow Claim 6, step (c) accordingly. While the phrase "about three millimeters" is not as precise as possible, the claim avoids indefiniteness because it is not "insolubly ambiguous." Honeywell Int'l, 341 F.3d at 1338; see also Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001).

Second, Defendant contends that Step (c)'s use of the word "epidermis" renders it indefinite. Defendant queries how the epidermis, which it defines as "the surface layer of the skin," can be incised in Step (c) if the epidermis has already been incised in Step (a) ("forming a first circumferential incision … in the epidermis …"), 9 noting that the top layer of skin cannot be incised twice. The specification only adds to the confusion, Defendant asserts, because it instructs the surgeon to make a "second circumferential incision of the redundant epithelium approximately 3 millimeters cranial from the first incision." Defendant notes that a medical dictionary defines epithelium as "the covering of internal and external surfaces of the body." See DORLAND'S ILLUSTRATED MEDICAL DICTIONARY 400 (26th ed. 1981). In other words, Defendant argues that the definitions of epidermis and epithelium are mutually exclusive because cutting into the epithelium requires cutting through the epidermis and the underlying layers; thus, both terms cannot be used to describe the skin to be incised in Step (c). Plaintiff counters that "epithelium" and "epidermis" can be used interchangeably when referring to a feline's claw.

9 Because of its use of the words "and then" between all steps, Claim 6 requires the surgeon to have completed Steps (a) and (b) before moving to Step (c).

A word will not render a claim invalid if it can be given any reasonable meaning: "If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds," Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1347 (Fed. Cir. 2005) (citing Exxon Research & Eng'g, 265 F.3d 1371, 1375 (Fed. Cir. 2001)). In this case, the '579 patent's subject matter, the other steps in Claim 6, the specification's language, and Figure 2, all taken together, adequately instruct a person skilled in the art that the word epidermis, as used throughout Claim 6, simply means "skin," and does not refer only to the skin's top layer. 10 The patent's intrinsic evidence conveys that the second incision must occur after the first incision during which some skin will have already been retracted. The intrinsic evidence also makes clear that the second incision's purpose is to retract more skin for covering the post-operative wound. Although the claim is certainly not an example of clear drafting, a person skilled in the art would be able to discern the meaning of the word "epidermis" as used in Step (c). Thus, the word does not render the claim indefinite.

10 Indeed, this more general definition has been used in at least one respected medical dictionary. See TABLER'S CYCLOPEDIC MEDICAL DICTIONARY (17th ed. 1993) (defining "epidermis" as "skin").
Here, the disputed terms are found in Claim 1 of the '476 patent, which states that the claimed device, "a portable rail grinding machine," comprises "means mounting the grinder on the frame for adjustably setting the stone between horizontal and vertical positions and therebetween . . . ." Id. (emphasis added). Portaco argues that the language "and therebetween" is a claim limitation, such that the grinder claimed under the patent must be adjustable to vertical and horizontal positions, as well as angles between vertical and horizontal.

The Court agrees with Portaco's proposed claim construction. Claim 1 of the '476 patent specifically states that the grinder includes a means to adjust the angle of the grinding stone "between horizontal and vertical positions and therebetween." The use of the word "and" before "therebetween" indicates that the ability to adjust the angle of the grinding stone to an angle between vertical and horizontal is a required claim element. Therefore, the Court construes the claim term "and therebetween" to mean: the angle of the grinding stone must be adjustable to vertical and horizontal positions, as well as angles between vertical and horizontal.

"Thereby"

At the charge conference, the district court explained to both parties that it would not construe the "thereby" clause because the claim limitation was clear in its meaning. The court explicitly instructed the jury on the term "continually," and then instructed that the jury should give the rest of the terms their ordinary meaning unless it appeared that the inventor used the terms differently. BSC argues that the court erred in leaving construction of the "thereby" clause to the jury because, by not specifically instructing on this limitation, the limitation was effectively read out of the claim. However, the court's instruction was proper, and the testimony of the expert witnesses at the hearing on claim construction supported the district court's conclusion that the limitation was clear in its meaning.

BSC's expert witness, a patent law expert, stated that the term "thereby" is a common expression and provided a simple and common definition for it. Bard's expert witness, a person of ordinary skill in the art of catheter design, stated that the "thereby" language is not redundant and further clarifies the claim. Because the trial judge need not repeat or restate every claim term in order to comply with the notion that claim construction is for the court, we see no error in the district court's instruction. See U.S. Surgical Corp., 103 F.3d at 1568, 41 U.S.P.Q.2D (BNA) at 1236.

D. "Thereby Prevent the Build-up of Electrostatic Charge in the Fuel and the Resultant Arcing Which Causes the Breakdown of the Polymer Material Comprising the Fuel Injection System Component"

Claim 1 recites that the fuel injection system component is made of a composite material with electrically conductive fibers to provide an electrically conductive path to ground and "thereby prevent the build-up of electrostatic charge in the fuel and the resultant arcing which causes the breakdown of the polymer material comprising the fuel injection system component."

Honeywell says that the plain meaning of the phrase is "preventing the accumulation of electrons sufficient to create an arc that causes the polymer material of the fuel injection system component to deteriorate." Defendants say that the phrase means "preventing the accumulation of charge in the fuel such that arcing and deterioration of the polymer material used to make the housing [of the fuel filter] are avoided."

The interpretations proffered by the parties are quite similar. Indeed, the specification of the '879 patent describes the arcing phenomenon as follows:

Most of the charge is concentrated in that part of the cavity 42 closest to the body 38. When a grounding plane, such as
the body 38, is within "striking" distance of a charged body, the plane itself is a target for electron current flow. The energy which makes up the charge will then no longer pass through the body in an evenly distributed manner. This absorption of energy breaks down the material of which the housing 12 is made and results in microscopic pin holes in the housing 12. When a large concentration of these pin holes occurs in a small area, the material comprising the housing 12 breaks down and the housing leaks. Tests have shown that the striking distance is always less than or equal to the radius of the curved body.

'879 patent, col. 3, ll. 26-40. The essential difference between the interpretations is that Honeywell uses "fuel injection system component" while defendants use "housing [of the fuel filter]." Because "fuel injection system component" has already been interpreted to mean "fuel filter," see supra, Part IV.A, defendants' interpretation is correct.

The phrase "thereby prevent the build-up of electrostatic charge in the fuel and the resultant arcing which causes the breakdown of the polymer material comprising the fuel injection system component" is interpreted as follows:

Preventing the accumulation of charge in the fuel such that arcing and deterioration of the polymer material used to make the housing of the fuel filter are avoided.

4120

j. "thereby simplifying assembly of said shifter"

The term "thereby simplifying assembly of said shifter" means allowing manual manipulation and positioning of the internal components of the shifter.

4121

The parties appear to dispute, for the two "surface temperature" claim limitations whether the temperature must be measured using a borehole reading. Defendants offer extrinsic evidence to support their proposal that the temperature readings can be made only at a borehole. Nowhere in the claims or specification, or as far as the Court can determine, in the prosecution history does the patentee use the word "borehole." Necessary to the invention is the reduction in temperature of the surface of the coal mine, not the borehole. The Court construes "reduction of the surface temperature of combustible material in said sealed portion to about 90° F" to mean "lowering of the surface temperature of material capable of burning in the sealed portion to approximately 90° F." The Court construes "thereby to lower the temperature at the surface of combustible material at said area" to mean "in order to lower the temperature at the surface of the combustible material at said area."

4122

A. "Therein"

The disputed term appears as follows: "a housing defining at least one compartment therein having an inlet aperture and an outlet aperture."

The parties agree that "therein" means that the housing consists of at least one compartment but may consist of multiple components. The parties dispute whether "therein" also means that the phrase "having an inlet aperture and an outlet aperture" applies to each of the one or more compartments that a housing defines, or only to at least one of the one or more compartments. Seitz contends that the term "therein" means that "[t]here are one or more compartments in the housing. The at least one (one or more) compartments each have an inlet aperture and an outlet aperture." (Docket Entry No. 76 at 4). Envirotech contends that the term means: "A single housing defines (marks the limits of) a single compartment or multiple compartments. Each compartment lies within the single housing. At least one compartment within the single housing has an inlet aperture and an outlet aperture. Other compartments, if any, may or may not have an aperture or apertures. The housing may or may not have an aperture or apertures." (Docket Entry No. 78 at 1).
As both parties read the words, "therein" at least means that a housing must have at least one compartment, but may have more than one compartment. The issue is whether the word "therein" means that the words "having an inlet aperture and an outlet aperture" refer to only one compartment in the housing, or to each of the more than one compartments in the housing.

The parties agree that if there is only one chamber in a housing, that chamber must have an inlet aperture and outlet aperture. The parties disagree as to whether, if there is more than one chamber, each chamber must have an inlet and outlet aperture, as long as at least one chamber is so equipped. The specifications make it clear that in a multi-chamber embodiment, each chamber has an opening to permit the water to flow in, to contact the heating element, and to permit the water to flow out, to the next successive chamber or to the outlet line that discharges the water from the housing. If there is more than one chamber within a housing, each chamber must have an opening for the water to enter and another opening for the water to flow out.

Claim 10 clearly states that if the housing consists of a single chamber, that chamber must have an inlet aperture and an outlet aperture. Claim 10 does not say whether, if the housing consists of more than one chamber, each chamber must have an inlet aperture and outlet aperture. The specifications refer to a series of reduced-aperture fluid couplings connecting one chamber to another. The terms "inlet line" and "outlet line" and "fluid outlet" refer to the flow of water into and out of the first chamber and the last chamber. (‘880 Patent, col. 7, ll. 49-59, col. 8, ll. 33-39; ‘971 Patent, col. 7, ll. 49-61, col. 8, ll. 36-39). In dependent claim 7 and dependent claim 16, the distinction between "inlet aperture" and "outlet aperture" on the one hand, and other openings or connections between or among a plurality of compartments is made even clearer. Claim 7 defines the "heater as defined in claim 1, wherein: the housing defines a plurality of compartments therein each fluidly connected in the series between the inlet aperture and the outlet aperture." (‘880 Patent, col. 22, ll. 28-31; ‘971 Patent, col. 21, ll. 54-57). Claim 16 describes "[t]he heater as defined in claim 10, wherein: the housing defines a plurality of compartments therein each fluidly connected in the series between the inlet aperture and the outlet aperture." (‘880 Patent, col. 23, ll. 17-20; ‘971 Patent, col. 22, ll. 49-51). It appears, from the limited submissions the parties have provided, that "inlet aperture" and "outlet aperture" refer to the initial and last opening that is in one chamber when it is the only one, and into the first chamber and out of the last chamber when there are a plurality of chambers. On this reading, Claim 10 does require that in a single-chamber embodiment, the chamber must have an inlet and outlet aperture, but does not require that every chamber in a multi-chamber embodiment must have an inlet and outlet aperture.

Envirotech's argument that the words "having an inlet aperture and an outlet aperture" cannot refer to the housing is supported by neither the claim language nor the specifications. The specifications describe water flowing into a chamber through a fluid inlet line and into the bottom of a chamber to contact the heating element. In a multi-chamber embodiment, the water flows through a series of reduced-aperture fluid couplings that link one chamber to another. The water is discharged from the last chamber through a fluid outlet line and into the fluid outlet. (‘880 Patent, col. 7, ll. 55-67; ‘971 Patent, col. 7, ll. 53-67).

The plain meaning of the words is that a housing must consist of at least one compartment that has an inlet aperture and an outlet aperture. Claim 10 does not state whether each of the compartments in a multi-compartment configuration must have an inlet aperture and outlet aperture, although it appears clear that each chamber must have openings for the water to flow from one chamber to the next, through that chamber, and into the following chamber. To the extent Envirotech argues for a construction that the housing "may or may not have an aperture or apertures," it is rejected as inconsistent with the claim language and specifications.

This court construes the term "therein" in Claim 10 of the '880 and '971 patents to mean that a housing must have at least one compartment or chamber within it that has an inlet aperture and an outlet aperture. A housing may have more than one compartment or chamber. A housing must have an inlet aperture and an outlet aperture.

All claims call for a receiving aperture with either a projection or a recess "therein." Zettl and Defendants disagree as to whether the claims thus allow for a projection or recess to be located at the very beginning of the aperture, or whether such
projection or recess must always be located some distance away from the beginning, inside the aperture.

The Court finds that the plain meaning of "therein" would ordinarily encompass situations where the projection or recess was located at the beginning of the aperture. "Therein" means in or into that place. Webster's, at 2372. A projection located at the aperture's edge is still a projection "therein," as it would be if the projection were moved a fraction of a centimeter inside the edge. This common understanding is best illustrated by analogy to sports. A ball is ordinarily considered still to be "within" bounds and "in" play even if the ball is right on the boundary line of the field of play.

Having said that, the Court must, however, consider whether Zettl abandoned the broader meaning of "therein" and chose, instead, to adopt a narrower understanding in an effort to distinguish its patent from prior art. The Zur patent, which preceded the '664 patent, discloses an earring composed of two ornamental components, hinged together on one side, with a fastening device located on the opposite ends of each of the components. The fastening device consists of a pin attached to a structure extending away from the end of one ornamental component and a simple hole located on another structure extending away from the end of the other ornamental component. The earring is engaged in the ear by inserting the pin through a perforation in the ear and latching the pin to the edge of the hole by means of a recess near the terminal end of the pin.

During reexamination, the Examiner initially rejected Claim 1 of the '664 patent in light of the Zur patent, remarking, among other things, that "the edge of the aperture 12 (the "Zur hole") can be considered to be a projection of the wall of the aperture." (Office Action in Reexamination, June 22, 1998, at 4). Zettl responded by insisting that the edge of Zur's hole cannot be, at the same time, the edge of the aperture and its projection. (Amendment, Sept. 9, 1998, at 22-23). Zettl argued that the '664 patent shows three separate and distinct components to the fastening means: a recess, an aperture, and a projection. (Id.) Zettl concluded that if, as the Examiner stated, "the recess engages the length of the wall, the edge of the aperture is not the projection which holds [the recess on the pin]." (Id. at 23) (emphasis in original).

Contrary to the arguments of Defendants, Zettl's statements to the Examiner was not an admission that the projection or recess cannot be located at the edge of the aperture. Rather, the statements merely clarified that the projection or recess must be a structure that is distinct from the surface of the ornamental component that gives the aperture its shape. Therefore, the Court finds that the '664 patent calls for a projection or recess to be located anywhere in the aperture, including at the beginning of the aperture, as long as the projection or recess is a structure that is distinct from the surface of the ornamental component that gives the aperture its shape.

C. "Thereon"

Tessera proposes that the TI construction of "thereon" be applied here: "The terminals are on or upon a single layer of the sheetlike element. When there are multiple layers in the sheetlike element and the terminals are thereon one of the layers, they are thereon the sheetlike element even though they must also be under another of its layers." See TI Order at 15. Samsung's proposed construction of "thereon" is "on or upon."

In urging the Court to adopt the TI construction, Tessera argues that Samsung seeks to ignore the "layering" issue that was previously argued and resolved by this Court in the TI Order. However, Tessera's proposed construction for "thereon" would also effectively mean "therein," which is inconsistent with the specifications. See '977 patent col. 10:31-33; 14:8-10. Thus, the Court construes "thereon" to mean "on or upon." 2

--- Footnotes ---

2 The Court acknowledges that the adopted construction deviates from that in the TI Order.

--- End Footnotes ---
2. "having a pressurizable member of a medical apparatus for interacting with the patient's body resting thereon"

KCI does not dispute Safe Bed's construction of most of this claim element. A "pressurizable member," in the context of the '939 patent, refers to a component or element that can be pressurized above atmospheric pressure, such as an inflatable turning device or a therapeutic air mattress. (Safe Bed's Mem., at 17-18; KCI's Mem., at 38-40). A "medical apparatus" refers to the hospital bed itself. (Safe Bed's Mem., at 17-18; KCI's Mem., at 38-40). KCI does dispute, however, Safe Bed's construction of the word "thereon" as used in the phrase "interacting with the patient's body resting thereon." The dictionary definition of "thereon" is simply "on that." WEBSTER'S, at 2372. In KCI's construction of the term, "thereon" indicates that there is contact between the patient's body and the pressurizable member. (KCI's Mem., at 39). According to Safe Bed, that contact is unnecessary. (Safe Bed's Reply, at 31).

Maintaining that "thereon" does not require direct contact but can refer to indirect contact between a patient's body and any structure underneath it, Safe Bed posits the example of a patient lying on a mattress covered by a sheet, noting that the patient would still be considered resting on the mattress, although not in direct contact with it. (Safe Bed's Reply, at 31). Arguing that there must be contact between the patient's body and the pressurizable member, KCI takes Safe Bed's argument to its logical extreme and submits that under Safe Bed's interpretation, a person walking on a raft floating on a river would be considered to be walking on the water. (KCI Mem., at 39). The parties' analogies, while creative, fail to resolve their dispute over this claim element.

This argument is really over whether this claim element can be construed to cover an inflatable turning device positioned underneath the mattress or patient support assembly. (KCI's Mem., at 38-39; Safe Bed's Reply, at 31). Obviously, focusing on the word "thereon" is of little aid in resolving this dispute. The remainder of the phrase, however, provides some clues. The patient's body must "rest" on the pressurizable member. "Rest" is defined as "to have place; sit or lie fixed or supported." WEBSTER'S, at 1935. If a person is resting on a mattress, one would not ordinarily consider that person to be resting on everything that might lie beneath the mattress as well. In addition, the pressurizable member must "interact" with the patient's body. That means the pressurizable member and the patient's body must "act upon each other" or "have a reciprocal effect or influence." WEBSTER'S, at 1176. An inflatable device that turns a mattress from underneath it might be considered to be acting upon that mattress, but would not ordinarily be considered to be acting upon a person lying on that mattress. The device exerts an influence on the mattress, which in turn exerts an influence on the person. The sense gained from the meanings of these other terms tends to support KCI's construction of this claim element. Accordingly, the Court adopts KCI's construction of this claim element to require the pressurizable member to be one on which the patient's body is resting.

2. Location of the Adjustment Means (claims 5 and 7).

The language at issue in claim 5 states: "said connection means having adjustment means thereon for infinitely adjusting the tracking of the mower by adjusting the output of one of said right and left hydraulic pumps." '961 Patent, col. 7, lines 1-4 (emphasis added). The language at issue in claim 7 states: "said connection means including adjustment means thereon for infinitely adjusting the tracking of the mower by adjusting the output of at least one of said right and left hydraulic pumps." '961 Patent, col. 8, lines 27-30 (emphasis added).

Toro maintains that while claim 5 does state that the connection means has the adjustment means "on" it, claim 7 states instead that the connection means "includes" the adjustment means. Toro says that the term "including" is not synonymous with the phrase "having thereon" -- the language in claim 5 which describes the relationship of the adjustment means to the connection means. Toro contends that the adjustment means could be physically attached to the connection means in any number of ways without being actually located on the connection means. Claim 5 is thus intended to represent a narrower limitation than claim 7, since "to be located on" is a narrower relationship than 'including,' meaning 'being a part of.'" Toro's Brief at 4. Toro contends that when claims use different language, the doctrine of claim differentiation provides that a
difference in meaning is intended. See Karlin Tech., Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-972 (Fed. Cir. 1999).

Scag, however, maintains that the language of the claims and the prosecution history of the '961 patent require me to find that the adjustment means must be literally "on" the connection means. Scag argues that the broad claims Exmark originally submitted to the PTO did not state that the adjustment means was to be located on the connection means. Exmark amended those original broad claims, however, when the PTO found they were anticipated by a Scag patent, U.S. Patent 4,967,543. Exmark therefore subsequently amended claim 5 to state the limitation that the "connection means having adjustment means thereon" and claim 7 to state the limitation that the "connection means including adjustment means." Exmark told the PTO that claim 5 "specifically describes that the connection means includes adjustment means," and that Scag's patent did not have a connection means that included an adjustment means. Exmark further told the PTO that claim 7 was "generally similar" to claim 5 and should be allowed for the same reasons as claim 5. Scag claims that these statements to the PTO estop Toro from contending that claim 5 somehow differs from claim 7.

The United States Supreme Court recently considered how patent claim amendments affect an alleged infringer's defense of prosecution history estoppel. The Court observed that if a patentee decides to amend a claim rejected by the PTO rather than appeal the rejection, the amended claim "is taken as a concession that the invention as patented does not reach as far as the original claim." Festo Corp. v. Shoketsu Kinzoku Kogyo Kabushiki Co., 152 L. Ed. 2d 944, 121 S. Ct. 1831, 1838 (2002). Prosecution history estoppel arises if the claim is amended "to secure a patent and the amendment narrows the patent's scope. . . . A patentee who narrows a claim as a condition for obtaining a patent disavows his claim to the broader subject matter, whether the amendment was made to avoid the prior art or to comply with § 112." 122 S. Ct. at 1840. The patentee must prove both that the claim was not amended "for a reason that would give rise to estoppel" and that "the amendment does not surrender the particular equivalent in question." 122 S. Ct. at 1842 (citing Warner-Jenkinson v. Hilton Davis Chem. Co., 520 U.S. 17, 33, 137 L. Ed. 2d 146, 117 S. Ct. 1040 (1997)).

The prosecution history here clearly indicates that Toro is estopped from asserting claims 5 and 7 have different meanings with regard to the location of the adjustment means. When the PTO rejected Exmark's broad claims that had not required the adjustment means to be physically located on the connection means, Exmark decided to limit the claims by situating the adjustment means on the connection means. Because Exmark's amendment narrowed the scope of the patent, Exmark cannot claim protection for the subject matter it surrendered in that amendment. I therefore find that claims 5 and 7 should be interpreted to mean the same thing: since the connection means includes the adjustment means, the adjustment means is physically located on the connection means.

The parties also dispute the meaning of "said handle and said rotatable joint having a common pivot axis therethrough." Both sides generally agree that the handle and the joint rotate around a shared axis. Rexon argues that because the claim expressly refers to the entire handle, and not merely a portion of the handle as described in other parts of the claim, the axis must pass "entirely through the handle." However, I do no disservice to the claim and its clear effort to distinguish between the handle as a whole and parts thereof by failing to construe the claim as Rexon proposes. Because the claim language refers simply to the handle and not any specific part of it, the axis must pass through the handle: not any particular part of it. Adding the word "entirely" imposes a limitation on the claim that is simply not contemplated by the claim language or the specification. The claim terms are construed as "an axis of rotation that passes through the handle and the rotatable joint."

The term "thermal adhesive net" is found only in the method claims of the patents-in-suit. For example, Claim 5 of the 779 Patent, a method claim dependent on Claim 1, requires that "said bonding element is a thermal adhesive net having a density of approximately 8 to 80 grams per square meter." 779 Patent at 7:5-7 (emphasis added). Claim 10 of the 779 Patent, another method claim dependent on Claim 1, requires that "said bonding element is a thermal adhesive web or net composed entirely of a thermal adhesive." 779 Patent at 7:25-28 (emphasis added). Claim 12 of the 615 Patent uses the term
in the exact same way as it was used in Claim 5 of the 779 Patent. 615 Patent at 7:36-39.

Taltech asks the Court to construe "thermal adhesive net" to mean "a regular array of thermal adhesive material." Taltech did not provide any new arguments regarding this term in addition to those presented for the term "thermal adhesive web." Esquel asks the Court to construe "thermal adhesive net" to mean "a two dimensional structure made by crossing thermal adhesive fibers at regular intervals." Esquel relies on the specifications and on general purpose and specialized dictionary definitions of "net." Both parties agree that "thermal adhesive net" has a "regular" element to it. Both parties use "thermal adhesive" in their proposed constructions of "thermal adhesive net." The parties' dispute centers on whether a "thermal adhesive net" must be fibrous and whether it must have openings.

The Court finds Taltech's less restrictive construction more persuasive. For the same reasons outlined above in the discussion of "thermal adhesive web," the Court rejects Esquel's requirements that the net be fibrous and have openings. The Court declines to impose any limitations from the dictionary definitions provided by Esquel onto the claims. As noted in the discussion of "thermal adhesive web," the specifications of the patents-in-suit distinguish a thermal adhesive "web" from a "net" by characterizing a net as being "more solid structured" than a web. 779 Patent at 3:53-4:2; 615 Patent at 3:54-4:3. The Court incorporates this language into its construction of the terms "thermal adhesive web" and "thermal adhesive net." Nothing in the claims indicates that "net" should not be interpreted as being more solid structured than a "web" across all claims.

Accordingly, the Court adopts Taltech's proposed construction, with modification, and construes the term "thermal adhesive net" to mean "a regular array of thermal adhesive material that is more solid structured than a thermal adhesive web."

12. "Thermal Adhesive Web"

The term "thermal adhesive web" is found in both the method and product claims of the patents-in-suit. For example, Claim 10 of the 779 Patent, a method claim dependent on Claim 1, requires that "said bonding element is a thermal adhesive web or net composed entirely of a thermal adhesive." 779 Patent at 7:25-28 (emphasis added). Claim 11, a method claim dependent on Claim 10, states that "said thermal adhesive web is composed of a plurality of adhesive filaments having a diameter ranging approximately between 20 to 80 microns." 779 Patent at 7:29-33 (emphasis added). Claim 12, another method claim dependent on Claim 10, states that "said thermal adhesive web has a density of approximately 10 to 100 grams per square meter." 779 Patent at 7:34-37 (emphasis added). Claim 27 of the 779 Patent, a product claim dependent on Claim 20, states that "said bonding element is a thermal adhesive web composed entirely of thermal adhesive." 779 Patent at 9:3-5 (emphasis added). Claims 2-4 of the 615 Patent use the term exactly as it was used in Claims 10-12 of the 779 Patent. 615 Patent at 7:1-10. Claim 20 of the 615 Patent uses the term exactly as it was used in Claim 27 of the 779 Patent. 615 Patent at 8:34-36.

Taltech asks the Court to construe "thermal adhesive web" to mean "a random array of thermal adhesive material." Taltech relies on the claims, on the specifications, and on the opinion of Taltech's expert, Dr. David Hall. Esquel asks the Court to construe "thermal adhesive web" to mean "a two dimensional structure made by randomly crossing thermal adhesive fibers" to create openings. Esquel relies on the specifications and on specialized dictionary definitions of "web." Both parties agree that "thermal adhesive web" has a "random" element to it. Both parties use "thermal adhesive" in their proposed constructions of "thermal adhesive web." The parties' dispute centers on whether a "thermal adhesive web" must be fibrous (i.e., containing filaments) and whether it must have openings.

Esquel asserts that a "thermal adhesive web" must be fibrous. The Glossary of Fusible Interlining Technology defines "adhesive web" as "an adhesive resin in form of a fibrous network." INDA, Ass'n of the Nonwoven Fabrics Indus., Glossary of Fusible Interlining Technology, Bobbin, Oct. 1981, at 57 (docket no. 97, Ex. J at 57). The Man-Made Textile Encyclopedia defines "web" as "[a] random fibrous structure used in the manufacture of nonwoven textiles." Man-Made Textile Encyclopedia 901-02 (1959) (docket no. 97, Ex. B at 901-02). Despite the reference to "fibrous" structures in these definitions, the Court reads the term "thermal adhesive web" to require fibers or filaments only when the claims themselves use such language. As outlined above, Claim 11 of the 779 Patent, which has not been placed directly at issue here, defines thermal adhesive web as being composed of filaments having a certain diameter. In contrast, the language in Claim 10 of the
779 Patent merely requires that the thermal adhesive web be composed "entirely of thermal adhesive." The inclusion of the specific "filaments" limitation in Claim 11 indicates that the limitation does not properly belong in all claims. The Court applies the principles of claim differentiation to give the other claims a broader scope because to read otherwise would make Claim 11 redundant. See Phillips, 415 F.3d at 1324-25.

In its effort to construe "thermal adhesive web" to include fibers (i.e., filaments), Esquel argues that the 779 Patent specification's "preferred embodiment" refers to "the adhesive web" as being "manufactured from a plurality of filaments. . . ." 779 Patent at 3:62-63 (emphasis added). The Court refuses to import limitations from a "preferred embodiment" outlined in the specification into the claims. See Eolas Techs. Inc. v. Microsoft Corp., 399 F.3d 1325, 1337 (Fed. Cir. 2005) (commenting that it is improper to limit claims to the preferred embodiment).

In addition to a fibrous structure, Esquel proposes a construction that would require openings in the thermal adhesive web. The patents-in-suit do not discuss or illustrate "openings" of any kind in the thermal adhesive. As a result, the Court does not interpret the term to require openings.

The specifications of the patents-in-suit distinguish a thermal adhesive "web" from a "net" by characterizing a net as being "more solid structured" than a web. 779 Patent at 3:53-4:2; 615 Patent at 3:54-4:3. The Court incorporates this language into its construction of the terms "thermal adhesive web" and "thermal adhesive net." Nothing in the claims indicates that "net" should not be interpreted as being more solid structured than a "web" across all claims.

Accordingly, the Court adopts Taltech's proposed construction, 10 with modification, and construes the term "thermal adhesive web" to mean "a random array of thermal adhesive material that is less solid structured than a thermal adhesive net."

10 In adopting Taltech's proposed construction, the Court does not rely on the opinion of Taltech's expert, Dr. Hall, see Hall Decl., docket no. 95, PP 5-6, because it is merely conclusory. See Phillips, 415 F.3d at 1318.

4130

Thermal Characteristic

The Thermal Characteristic Patents' claims require the PCD body to exhibit a "thermal characteristic such that a 950 degrees C. temperature at the working surface results in a temperature of less than 750 degrees C. at the depth." ReedHycalog argues this term does not require construction. Defendants contended the claimed thermal characteristic is indefinite and, in the alternative, argue the term is not enabled. The Court addressed this dispute in Tyler I, concluded the claimed thermal characteristic was definite, and found the term did not require construction. Defendants do not raise any new or persuasive arguments in this case.

The Thermal Characteristic is Definite

The Thermal Characteristic Patents claim a PCD element or method to produce a PCD element such that "said bonded diamonds exhibit a thermal characteristic such that a 950 degrees C. temperature at the working surface results in a temperature of less than 750 degrees C. at the depth." E.g., '447 Patent, col. 14:24-33. The claim language exactly defines the claims' bounds--a 950 [degree] C temperature at the working surface results in a temperature less than 750 [degree] C at the depth from the working surface. Defendants argue that an ordinarily-skilled artisan would not know if a partially-leached PCD element contains the claimed thermal characteristic because the specifications do not disclose the conditions, tests, or methods to measure the claimed "thermal characteristic."

Defendants' arguments are without merit. A claim is invalid as indefinite under 35 U.S.C. § 112 P 2 if the claim fails to particularly point out and distinctly claim the subject matter the applicants regard as the invention. The primary purpose of the definiteness requirement is to ensure public notice of the scope of the patentee's legal protection, such that interested members of the public can determine whether or not they infringe. Halliburton Energy Servs., Inc. v. M-I, LLC, 514 F.3d 1244, 1249 (Fed. Cir. 2008). Thus, the definiteness inquiry focuses on how a skilled artisan understands the claims, and a claim is indefinite if the accused infringer shows by clear and convincing evidence that "a skilled artisan could not discern
the boundaries of the claim based on the claim language, the specification, and the prosecution history, as well as her knowledge of the relevant art area.” Id. at 1249-50.

A claimed parameter is definite “when the relevant values can be 'calculated or measured.’” Marley Mouldings Ltd. v. Mikron Indus., Inc., 417 F.3d 1356, 1360 (Fed. Cir. 2005) (quoting W.L. Gore & Assoc., Inc. v. Garlock, Inc., 721 F.2d 1540, 1558 (Fed. Cir. 1983)). However, a claim's bounds are not sufficiently defined where the number of methods used to measure the claimed parameter, the different results each method yields, and the uncertainty as to which method to use render the parameter insolubly ambiguous and effectively incapable of measurement. Honeywell Int'l, Inc. v. Int'l Trade Comm'n, 341 F.3d 1332, 1339-41 (Fed. Cir. 2003); Halliburton, 514 F.3d at 1249; see also Marley Mouldings, 417 F.3d at 1360. Thus, a claimed parameter is indefinite where the accused infringer shows by clear and convincing evidence: (1) persons of ordinary skill in the art, at the time the application was filed, knew of multiple methods to measure the claimed parameter; (2) the different methods yield significantly different results such that the claims are insolubly ambiguous as a result; (3) and the intrinsic record or knowledge of the relevant art area do not sufficiently define the bounds of claim by specifying to a skilled artisan which method or method of set of measurement methods to use. See Kinetic Concepts, Inc. v. Blue Sky Med. Group, Inc., 554 F.3d 1010, 1022 (Fed. Cir. 2009); Marley Mouldings, 417 F.3d at 1360; Honeywell, 341 F.3d at 1339-41; Halliburton, 514 F.3d at 1249-50; In re Gabapentin Patent Litig., 395 F. Supp. 2d 164, 173 (D.N.J. 2005).

Defendants merely state the specifications do not describe a method to test for the claimed thermal characteristic. Defendants do not explain why that alleged omission is fatal--Defendants do not show that skilled artisans were aware of multiple methods to measure the claimed thermal characteristic and that the methods produced significantly varied results such that the thermal characteristic cannot be calculated or measured. See Honeywell, 341 F.3d at 1340-41. Without such a showing, it is irrelevant that the specifications allegedly do not disclose a method to test the claimed thermal characteristic. See Marley Mouldings, 417 F.3d at 1358, 1360; Gabapentin, 395 F. Supp. 2d at 173.

Further, Defendants' allegations do not show by clear and convincing evidence that the intrinsic record or knowledge of the relevant art area do not specify to a skilled artisan which method or method of set of methods to use. The specifications describe using a wear test to calculate a wear index for a partially-leached PCD element. '447 Patent, col. 10:21-col. 11:11. During these tests, friction at the working surface inputs heat into the PCD element, and the tests allow a skilled artisan to calculate a wear index for the PCD element. Id. at col. 10:20-37, col. 11:1-11. The higher the wear index from this test, the more heat the leached portion of the PCD element can withstand before it degrades. Id. at col. 10:34-37, col. 10:66-col. 11:26.

A person of ordinary skill can infer the working surface's temperature when he performs the wear test. ReedHycalog's expert in Tyler I, David Hall, declared that the leached portion of the PCD element emits different colored light depending on its temperature during the wear test. Tyler I Claim Construction Opinion & Order, 6. Hall further declared that those skilled in the art know that emissions of orange light and white-hot light indicate the working surface of the PCD element is 950 [degree] C. Id. Defendants do not argue or submit evidence to the contrary.

The specifications also explain how an ordinarily-skilled artisan can infer that the temperature of the unleached portion of the PCD element did not reach 750 [degree] C during the wear test. The specifications detail the two modes of thermal degradation of unleached PCD elements, due to different thermal expansion rates (at about 400 [degree] C) and graphitization (at about 750 [degree] C). '447 Patent, col. 2:31-47, col. 9:12-34. Of interest here, the diamond in unleached PCD elements begins to graphitize as the temperature of the unleached PCD element approaches 750 [degree] C. Id. at col. 9:24-33. Thus, a person of ordinary skill could, after the wear test completes, inspect the PCD element for graphitization and infer whether the temperature of the unleached portion reached 750 [degree] C during the wear test. Tyler I Claim Construction Opinion & Order, 6. Defendants do not raise any arguments or present any evidence to the contrary.

In total, Defendants have not shown by clear and convincing evidence that the term "thermal characteristic such that a 950 degrees C. temperature at the working surface results in a temperature of less than 750 degrees C. at the depth” is indefinite. Thus, the Court concludes the term is definite. In addition, the claim language is clear and does not require construction. See Tyler I Claim Construction Opinion & Order, 8-9, 11.

4131

B. "automated thermal cycler"
Applera asks the court to construe this term as "an instrument for use in a nucleic acid amplification reaction comprising multiple thermal cycles for alternately heating and cooling samples." Stratagene advocates defining the term as "an instrument that can be programmed to heat and cool a surface or vessel." I adopt Applera's definition.

To define "automated thermal cycler," I must determine how a person trained in the art would have understood the term in 1991. In doing so, I must define the term in a manner consistent with the scientific and technical context in which it is used in the patent.” See AFG Indus., Inc. v. Cardinal IG Co., 239 F.3d 1239, 1248 (Fed. Cir. 2001).

Although the specification does not define "automated thermal cycler," it uses the term in a way consistent with Applera's proposed construction. Every reference to "thermal cycler" or "thermocycler" appears to identify an instrument used for conducting nucleic acid amplification reactions comprising multiple thermal cycles.

At the Markman hearing, Applera presented the testimony of Dr. Carl Batt, who testified that persons trained in the art in 1991 would have understood "automated thermal cycler" as a specialized instrument for use in a nucleic acid amplification reaction comprising multiple thermal cycles for alternately heating or cooling samples. I credit his testimony. Based on the fact that he authored a paper describing PCR technology submitted for publication in 1991 (see Tr. 74-76), I find that he was trained in the art in 1991 and is qualified to testify on this issue. Stratagene has presented no evidence suggesting that persons trained in the art of nucleic acid amplification in 1991 would have understood this term in any other way.

I acknowledge the Federal Circuit's admonition that extrinsic evidence is less reliable than intrinsic evidence. Phillips, 415 F.3d at 1318. In Phillips, the Federal Circuit advised courts to discount expert evidence at odds with the intrinsic evidence. Id. Nonetheless, consulting extrinsic evidence is appropriate when the internal evidence is ambiguous. See Storage Tech. Corp. v. Cisco Sys., Inc., 329 F.3d 823, 832 (Fed. Cir. 2003). Dr. Batt's testimony does not contradict the internal evidence; to the contrary, it is consistent with the specification's use of the term.

Stratagene's proposed construction is too broad and does not reflect the scientific and technical context of the patent. Stratagene's only support for its proposed construction is the specification's reference to "a spectrafluorometer capable of heating and cooling a surface, or vessel." (Col. 12, Ins. 14-15.) The specification contrasts this to a spectrafluorometer housed independently of a thermocycler. As Stratagene itself notes in its post-hearing brief, the specification was first drafted for the method patent application. For this reason, the specification reads more broadly than the claim itself. For example, as discussed below, the specification refers to various methods of DNA amplification, including isothermal reactions. But the claimed instrument is limited to reactions comprising multiple thermal cycles. Likewise, the specification refers to various methods of detecting nucleic acid amplification, even if the claimed instrument performs only one such method. My conclusion that the amplification reaction must comprise multiple thermal cycles reinforces the proper construction of "thermal cycler." The evidence shows that a person trained in the art in 1991 would have understood "thermal cycler" or "thermocycler" in the context of amplification reactions comprising multiple thermal cycles in the way suggested by Dr. Batt.

After reviewing the claim language, the specification, and the extrinsic evidence (i.e., Dr. Batt's testimony), the only conclusion consistent with the context of this patent is that "thermal cycler" refers to "an instrument for use in a nucleic acid amplification reaction comprising multiple thermal cycles for alternately heating or cooling samples."

DuPont asks the Court to construe the term "thermal distortion" as meaning "[t]he magnitude of change in the machine and transverse direction caused by thermal development of the flexographic printing plate." (DuPont Responsive Br. at 13.) But MacDermid advances the following construction of this term: "The magnitude of plate image distortion in the machine and transverse direction caused by thermal development of the flexographic printing plate that is measured by comparing the developed image of the flexographic printing plate with the image of the negative phototool." (MacDermid Opening Br. at 20.)
DuPont contends that its proposed construction should be adopted because it is: (1) supported by the plain language of claim 1 itself, which refers to thermal distortion "in both the machine and the transverse directions" ('758 Patent at col. 8, lines 21-22); (2) consistent with the specification, which states that the "[t]he thermal distortion (includes both elongation and shrinkage) of the plate in both the machine and the transverse directions is less than 0.03%" (id. at col. 2, lines 22-24) and (in Example 1) that "[t]he amount of distortion was well balanced between the machine and transverse directions" (id. at col. 5, lines 44-46); and (3) "[s]imple and straightforward" (Tr. at 84). (DuPont Responsive Br. at 12; Tr. at 84-88.)

As to MacDermid's proposed construction, DuPont argues that: (1) the '758 patent and its prosecution history are not limited to phototools or analog printing plates; (2) although the '758 patent contains no express "digital" references, "[i]t is well settled law that the '758 patent does not have to expressly describe embodiments directed to digitally imaged flexographic printing plates for the claims to be construed to cover digitally imaged plates" (DuPont Responsive Br. at 14 (citations omitted)); and (3) the proposed construction would require use of a single measuring technique even though the specification provides several examples of how to measure thermal distortion. (DuPont Responsive Br. at 13-14; Tr. at 84-88.)

DuPont counters MacDermid's assertions that DuPont's proposed construction would render the '758 patent insolubly ambiguous and indefinite by arguing that: (1) "[t]hermal distortion of an analog plate, a digitally imaged plate or the individual polymeric substrate are all easily measured by comparing the dimensions of the plate or substrate before and after being developed with heat" (DuPont Responsive Br. at 15); (2) in contrast to the infringer in Honeywell v. International Trade Commission, 341 F.3d 1332 (Fed. Cir. 2003), "MacDermid can only point to the arguments of its attorneys, not credible factual evidence, to support its contention that the particular method used to determine thermal distortion is 'critical' to determining thermal distortion" (DuPont Responsive Br. at 16); and (3) the patent does not have to describe a specific and exclusive measurement technique, as a person of ordinary skill in the art would know how to conduct the proper measurement and, at a trial, the parties' experts will explain how they measured the distortion. (Id. at 15-16; Tr. at 182-86.)

MacDermid defends its proffered construction on the grounds that: (1) the specification "only describes analog plates, analog imaging, and a measurement technique for thermal distortion of analog imaged plates" (MacDermid Opening Br. at 21); (2) the measurement of thermal distortion of the plate is only described in Examples 3 and 4 of the specification, and, in both instances, the method measures the developed image against the image on the "negative" ('758 Patent at col. 7, lines 16, 58-59); (3) the measurement technique identified in Examples 3 and 4 in the specification cannot be used with digitally imaged plates because "the in situ mask is thermally processed (and destroyed) during development" (MacDermid Opening Br. at 22); (4) the prosecution history confirms that the exclusive method of measuring thermal distortion is found in Examples 3 and 4, with the applicants stating "that Examples 3 and 4 additionally provide support and enablement for the invention as described in Claim 1" to overcome the examiner's enablement rejection (Prosecution History at 7-3); and (5) any construction of "thermal distortion" to include digital flexographic plates would render the claims invalid for failure to meet the enablement requirement and invalidate the claims of the subsequent '859 patent on anticipation grounds. (MacDermid Opening Br. at 20-23; MacDermid Reply Br. at 9-10; Tr. at 142-54.)

MacDermid also argues that DuPont's proposed construction of "thermal distortion" must be rejected because it would "render the claim limitation 'insolubly ambiguous' and indefinite." (MacDermid Opening Br. at 23.) Specifically, it contends that:

First, as noted, the '758 specification fails to describe any measurement technique of "thermal distortion" of a printing plate other than comparing the imaged surface to the analog phototool. Second, one could conceive of innumerable measurement techniques for "thermal distortion" of an imaged plate. Third, and most significant to the Court's evaluation of indefiniteness, these measurement techniques can result in varied and disparate results.

(Id. at 24.) According to MacDermid, the Court confronts a situation similar to the one addressed in Honeywell:

[T]here are two possible constructions of "thermal distortion" - the first is an "any one method" and the second is an "all methods." No guidance is given to the Court (or the public) as to which construction is correct, particularly, in the context of a digitally imaged plate. Moreover, different and potentially contradictory results are reached depending on the measurement method employed and/or the equipment used.

(Id. at 25-26.) MacDermid also contends that Examples 1 and 2 of the '758 patent, cited by DuPont, provide two methods to
measure the thermal distortion of the substrate, but that claim 1 is concerned with the thermal distortion of the plate while claim 19 expressly addresses the "distortion" in the "said polymeric substrate" (’758 Patent at col. 10, lines 4-5). (Tr. at 142-52.) MacDermid asserts that DuPont's proposed construction fails to define what should be measured and how it should be measured, and that DuPont improperly leaves it up to a jury to decide which measurement methodology is correct and thereby usurps the Court's responsibility of defining the scope of a patent claim. (Id.)

The parties present the Court with a difficult choice with their contentions. But the Court agrees with DuPont's arguments and adopts its simple and common-sense construction, which also has substantial support in the intrinsic evidence. It would be inappropriate to strike down this construction as indefinite, at least at this juncture. Thus, "thermal distortion" is construed to mean "the magnitude of change in the machine and transverse direction caused by thermal development of the flexographic printing plate."

Thermal stresses

The term "thermal stresses" is used in claim 16 of the '990 Patent. At the hearing, counsel for both parties stipulated to accept the following definition offered by the Court:

Forces, induced by heat, which tend to deform a body.

B. Claim 51

The parties also dispute the meaning of independent claim 51. The disputed element of this claim involves the same process step at issue in claims 1, 25, 32 and 34: the exposure of component materials to imaging radiation. Unlike those claims, claim 51 does not contain an homogenization requirement. It reads as follows:

A method for forming an integral object from a composition in a layer-by-layer process wherein properties within said object are changed, said process comprising the steps: providing a layer of composition; thermally changing the properties of the regions of the layer of composition by exposing the composition to imaging radiation and repeating steps a-b with subsequent applications of composition and exposure …; wherein the properties within said integral object are changed by varying the imaging radiation time, temperature, and/or intensity.

(’875 Patent, Col. 20, ll. 24-40) (emphasis added).

Defendants argue that the words "thermally changing the properties of the regions of the layer of composition by exposing the composition to imaging radiation" must be construed as requiring the formation of an alloy between substances, i.e., homogenization. They identify two aspects of the patent that purportedly mandate this construction. First, they claim that the specification does not teach a process of forming objects by means other than homogenization. Second, they claim that Lawton limited the scope of his invention to processes involving homogenization, as evidenced by language in the specification.

1 Defendants also point to the prosecution history in support of their argument. In the original patent application, each claim submitted by the inventor included a "homogenizing" step. In response to the Examiner's initial rejection of the claims, Lawton argued that the homogenizing step of his invention distinguished his claims from prior art. Those claims were eventually approved. When Lawton applied for a reissue patent, he included all of the claims from his original patent and twelve new claims, two of which (proposed independent claim 32 and dependent claim 33) omitted the "homogenizing" step. The Examiner initially rejected the newly proposed claims and rejected claim 32 on several grounds, including its
For these reasons, I find that the intrinsic evidence does not support a construction that would narrow claim 51 to require

anticipation by two prior art patents. In response, Lawton amended claim 32 by adding several limitations, including the step of "homogenizing the composition." Lawton asserted that the homogenizing step distinguished the claim from prior art and the Examiner allowed claim 32 to issue. With respect to dependent claim 33, the inventor responded to the initial rejection by converting the claim into independent form. That claim was issued as claim 51. Defendants argue that the Examiner's decision to allow the claim with little discussion, and the inclusion of a homogenization requirement in each of the other independent claims, is evidence that the claim implicitly includes an homogenization requirement; or alternatively, that the Examiner was hoodwinked into approving an independent claim unsupported by the specification.

Imagecure counters Defendants' proposed construction with the axiom that limitations from the specification cannot be imported onto a claim. See, e.g., Arlington Indus., Inc. v. Bridgeport Fittings, Inc., 345 F.3d 1318, 1327 (Fed. Cir. 2003). Nonetheless, there are many cases in which claims capable of being read broadly are instead held to narrower constructions based on statements in the specification. In Watts v. XL Sys., Inc., 232 F.3d 877, 883 (Fed. Cir. 2000), an invention--described broadly in the claims--was limited to particular structures identified in the specification because the specification stated that "the present invention utilizes [the structures]." In Kinik Co. v. ITC, 362 F.3d 1359 (Fed. Cir. 2004), the Federal Circuit ruled that a method claim for the manufacture of abrasive articles, whose plain language called for the use of a mixture of liquid binder and powdered material, was limited to mixtures containing a larger volume of liquid binder than powered material. The court limited the broader claim language because of language in the specification stating that volume of the liquid binder "substantially exceeds" the volume of the powder. Id. at 1364 (noting that the limitation was also found in the summary of the invention and was quantified in a detailed description of the embodiments). See also Toro Co. v. White Consol. Indus. Inc., 199 F.3d 1295, 1301 (Fed. Cir. 1999) (in which a claim was construed to encompass a particular structure when the specification described a particular structure as "important to the invention").

Those cases began, however, as all cases must: with the language of the claims. See, e.g., Watts, 232 F.3d at 882 (holding that the disputed claim language was not clear on its face before narrowing the claim language based on limitations in the specification). In this case, Defendants have not shown that the language of claim 51 should be given anything other than its ordinary meaning to one skilled in the art. Given the parties' agreement that Lawton acted as his own lexicographer with respect to the term homogenization, I am hard-pressed to believe that one skilled in the art would construe the language of claim 51 as implicitly requiring homogenization.

The structure of Defendants' argument belies the nature of their objection to this claim. Defendants compare the words of claim 51 ("thermally changing the properties of regions of the layer of composition") with the words of the other independent claims, such as claim 34 ("thermally homogenizing the dispersion by applying imagewise radiation"). They ask me to find that homogenization is implicitly incorporated by claim 51, notwithstanding its omission from the claim language, and they do so without identifying any language in the claim that would be ambiguous to one of ordinary skill in the art. Though Defendants raise a reasonable argument when they suggest that processes other than homogenization are not enabled by the specification, 2 that objection is properly raised in the context of the '875 patent's validity.

2 Throughout the specification, the invention is discussed in terms of, or with reference to, homogenization. For example, the "Field of the Invention" states: "The invention relates to a process of making models . . . using an imagewise exposure of a dispersion of components to radiation. The process is based on homogenizing the components of the dispersion to form an alloy which have properties different from the properties of the dispersion or its individual components." (‘875 Patent, Col. I, ll. 10-16.) Similarly, the "Summary of the Invention" states that "the invention comprises a process . . . comprising the steps of . . . homogenizing the dispersion." (Id. at Col. 2, ll. 9-15.) Within the specification the inventor distinguishes the "homogenization process of the invention" from the prior art of selective laser sintering, another process for manufacturing parts using layer-by-layer solid imaging. (Id. at Col. 4, ll. 9-10.) Nonetheless, the language of the specification does not exclude the process outlined in claim 51, and for the reasons discussed herein, I find no reason to read the homogenization requirement into the ordinary meaning of the claim.

For these reasons, I find that the intrinsic evidence does not support a construction that would narrow claim 51 to require
1. "thermally insulated brewing device"

a. The Parties' Proposed Construction

The parties dispute whether the phrase "thermally insulated brewing device" limits the scope of the claim. Capresso argues that "brewing device" refers to the coffee maker and asserts that the entire coffee maker must be "thermally insulated" or have some sort of protection to protect heat loss. DeLonghi argues that the limitation lacks support in the specification and is indefinite under 35 U.S.C. § 112, P 1. Sunbeam, in contrast, maintains that the phrase is part of the preamble and is not limiting.

According to Capresso, even if the term is part of the preamble, it is still a claim limitation which must be found within the accused device. See Seachange Int'l, Inc. v. C-Cor Inc., 413 F.3d 1361, 1375-76 (Fed. Cir. 2005) (preamble operates as a claim limitation of independent claim if it helps determine the scope of the claim and the claim that depends from it). Capresso notes that the limitations in the body of claims 1 and 7 both derive antecedent basis from the preamble. Claim 1 ("A thermally insulated brewing device comprising a thermal carafe. . ."); Claim 7 ("[t]he brewing device of claim 1, further comprising . . ."). Therefore, Capresso maintains that the preamble is an essential structure of the claims. Further, Capresso argues that "brewing device" should not be construed as the carafe because a thermal carafe is described later in the claim. Whenever the patent specifications or claims refer to the carafe, they do so by using the word "carafe," not "brewing device." Accordingly, Capresso argues that "thermally insulated brewing device" should be construed as "thermally insulated coffee maker."

Sunbeam makes two main arguments in response to Defendants' construction: (1) the disputed phrase is part of the preamble and does not limit the scope of the claim and (2) assuming arguendo that the preamble does limit the claim, a proper interpretation requires only the carafe and lid to be insulated.

First, Sunbeam argues that "thermally insulated brewing device" is not part of the claimed invention. It asserts that the phrase is a "work piece" or a "reference point" for the claimed invention. A "work piece" is an element necessary to describe an invention, but not a necessary element. SDS USA, Inc. v. Ken Specialties, Inc., 107 F. Supp. 2d 574, 593 (D.N.J. 2000) (holding that the term "ribbon stock" in the independent claims' preambles described the intended use of the apparatus but was not a claim limitation). Sunbeam advances two Federal Circuit cases for the proposition that a claim preamble has the import that the claim as a whole suggests for it, and a work piece does not limit the scope of a claim. See Schumer v. Lab. Computer Sys., Inc., 308 F.3d 1304 (Fed. Cir. 2002) (holding that the preambles at issue -- "point of origin," "angle of rotation," and "scale" -- did not limit the scope of the digitizer invention but simply described features that necessarily exit in any coordinate system for a digitizer); Vaupel Textilmaschinen KG v. Meccanica Euro Italia S.P.A., 944 F.2d 870 (Fed. Cir. 1991) (holding that the terms "breast beam" and "breast plate" were not structural limitations of the patented weaving machine and method but merely reference points to fix the direction of movement from the loom).

Sunbeam maintains that the purpose of the '719 patent was to provide a brewing device with a thermal carafe having insulated walls and an insulated lid. Sunbeam argues that a plain reading of the of the '719 patent makes clear that it pertains to thermally insulated carafes adapted for use in connection with an automated brewing device. Sunbeam directs the Court's attention to the introduction to the summary of the invention in the patent:

The present invention substantially improves upon the prior art by providing a thermal carafe brewing and dispensing device which has a brew-through lid which includes a liquid pressure controlled and activated valve to provide a unidirectional flow path into the carafe. In accordance with one aspect of the invention, a thermal carafe adapted for use in connection with an automatic drip brewing device includes a vessel with thermally insulated walls. . . (emphasis added).

Col. 1, lines 45-58. Sunbeam argues that the patentee did not intend to protect a brewing device that is insulated but instead a brewing device having a thermal carafe that is insulated.
Second, Sunbeam argues that even if the court finds that the preamble does limit the claim, the phrase "thermally insulated brewing device" does not require the entire coffee maker to be insulated but only a portion of it, namely the thermal carafe and lid. Sunbeam argues that this interpretation is consistent with the patent specifications and drawings. See FIG 1 and col. 2 lines 52-67 & col. 1, lines 1-34.

Sunbeam maintains that the fact that the specification does not refer to the "thermal carafe" as a brewing device does not render its interpretation invalid. The purpose of a preamble is to set out in terse terms what will be described in the claim language itself. The phrase "thermally insulated brewing device," it argues, merely indicates that some portion of the coffee maker described in limiting terms will have an insulated component. The claim language shows that two components are in fact insulated -- the carafe and the lid.

Finally, Sunbeam argues that insulating the entire coffee maker would serve no practical function and would exclude all of the embodiments of the invention disclosed in the '719 patent. Sunbeam points out that there is no need to insulate the brewing area, the base, or many other components of the coffee maker in order to achieve the goals of the patent. Sunbeam directs the Court's attention to the patent specification which describes the preferred embodiment to include only insulated carafes and lids. FIGS 1-6 & col. 2-5. Sunbeam cites Howe v. Medical Components, Inc., for the proposition that an interpretation which excludes the preferred embodiments cannot be sustained. 814 F.2d 638, 643-44 (Fed. Cir. 1987).

b. The Court's Construction

The key inquiry is whether "thermally insulated brewing device" is a claim limitation which limits the scope of the invention or whether it is merely a reference point. In Bell Comm'n's Research, Inc. v. Vitalink Comm'n's Corp., the Federal Circuit advised: "A preamble has the import that the claims as a whole suggests for it." 55 F.3d 615, 620 (Fed. Cir. 1995). A preamble limits an invention if it recites structural limitations of the claimed invention or if it is necessary to give life, meaning and vitality to the claim. Seachange Int'l, Inc., 413 F.3d at 1375 (citations omitted). However, where a patentee uses a preamble only to state a purpose or intended use for the invention, the preamble is not a claim limitation. Rowe v. Dror, 112 F.3d 473, 478 (Fed. Cir. 1997). Where the language of the body of the claim "sets out the complete invention in that it provides in detail the functional attributes of the device that performs the methods... the language of the preamble is superfluous" and is not a claim limitation. Schumer v. Lab. Computer Sys., Inc., 308 F.3d 1304, 1310 (Fed. Cir. 2003); Bristol-Myers Squibb Co. v. Ben Venue Labs., Inc., 246 F.3d 1368 (Fed. Cir. 2001). However, if limitations in the body of a claim rely upon and derive antecedent basis from the preamble, the preamble acts as a necessary component for the claimed invention. See Seachange Int'l, Inc., 413 F.3d at 1375-76.

Here, the preamble is the only antecedent basis to understand claim 7. Claim 7 states: "The brewing device of claim 1, further comprising. . ." The term "brewing device" is not used anywhere else in the claims or specifications. Consequently, it is an essential structure for the claims.

The issue, then, is how the preamble phrase affects the scope of the invention, and in particular, whether the preamble requires the entire coffee maker to be insulated or whether it is sufficient that the carafe and lid are insulated. Words of a claim are "generally given their ordinary and customary meaning." Philips, 415 F.3d at 1312 (citing Vitronics, 90 F.3d at 1582). However, claim terms must be read not only in the context of the particular claim in which the disputed term appears but in the context of the entire patent, including the specifications. Id. at 1313. The interpretation of the preamble should be consistent with the patent specifications which describe the preferred embodiments.

Capresso would have this Court interpret "thermally insulated brewing device" to mean a coffee maker whose entire structure is insulated. Although the Court agrees that the ordinary meaning of "brewing device" is coffee maker, it is unreasonable, in light of the purpose of the patent, the specifications, and the drawings to suggest that the invention is limited to coffee makers where all component parts are insulated. The purpose of the patent is to prevent heat loss from the brewed beverage. To fulfill this goal, there is simply no need to insulate the brewing area, base, or many other components. The claim indicates that two components of the coffee maker are to be insulated -- the carafe and the lid. The preferred embodiments likewise describe coffee makers with insulated carafes and lids. FIGS 1-6 & col. 2-5. Nowhere does the patent suggest that the entire structure is insulated. Accordingly, the Court finds that "thermally insulated brewing device" refers to a coffee maker that has some components which are insulated -- the carafe and the lid.
II. Part a) -- "50 to 95% cotton fibers...

A. Relevant Claim Language

The relevant language for this section consists of the following: "50 to 95% cotton fibers; 5-30% non-flame-retardant thermoplastic fibers in which warp yarns for woven fabrics are comprised of 50 to 95% cotton and 5 to 30% non-flame-retardant thermoplastic fibers." ('545 Patent, col. 8, lns. 30-34).

B. Parties' Positions

Defendants take issue with the term "thermoplastic fibers." They do not argue that the term is unclear or indefinite, but instead assert that the term, as used in Claim 1, must be construed with the following limitation - "thermoplastic fibers with a melting point above 200 degrees Celsius." In support of their assertion, Defendants point to the following language in the specification of the '545 Patent:

Thermoplastic fibers with a melting point above 200 deg C. such as 66 and 6 nylon, polyethylene terephthalate and other polyesters, must be used to prevent loss of fabric durability well below the degradation temperature of cotton. ('545 Patent, col. 3, lns. 32-36) (emphasis added).

In their rebuttal brief, Plaintiffs state, "While the specification does provide an example of thermoplastic fiber melting points required when a specific situation is desired, it makes no clear intention that all fabrics or all embodiments of the fabric require thermoplastic fibers with such specific melting points." (Pls.' Rebuttal at 10). Plaintiffs argue that this language "simply provided one exemplary situation where such fibers 'must' be used -- that is, situations in which the loss of fabric durability well below the degradation temperature is not desired (such as, for example, protection against prolonged radiant heat, molten splash, or in flash fires)." (Id. at 11). Furthermore, Plaintiffs point out that "the corollary to [the previous] statement is also supported by the specification -- that is, if loss of fabric durability below the degradation temperature of cotton is not a problem, then thermoplastic fibers without such specific melting point may then be used (such as, for example, where exposure is less intense, less prolonged, and less likely)." (Id. (internal citations omitted)).

C. Court's Construction

We agree with Plaintiffs. We conclude that the term "thermoplastic fibers" carries the ordinary meaning understood by people in this field: "fibers made from a plastic material that becomes soft when heated and hard when cooled." (Pls.' Rebuttal at 12). The term is not limited to a type of thermoplastic fiber with a specific melting point. The melting point of 200 degrees Celsius is only mentioned once in the '545 Patent -- no other instance in which thermoplastic fibers are discussed do the inventors mention any specific melting point. Moreover, when the statement referring to the melting point is read in its entirety, it is clear that the phrase "must be used" does not mean that a material with this melting point "must always be used," but rather that a material with this melting point must be used to achieve one specific purpose -- "to prevent loss of fabric durability well below the degradation temperature of cotton." We agree with Plaintiffs' assessment that the statement at issue "clearly does not rise to the level of a clear or unequivocal statement that a specific melting point of the thermoplastic fibers is required for all embodiments of the claimed invention." (Pls.' Rebuttal at 11.)
A steam cooking utensil comprising:

[A] a base;

[B] a boiling water reservoir defined by the base;

[C] a heater, mounted in the base to heat liquid in the boiling water reservoir;

[D] thermostat means, mounted in the base and coupled to the heater, for switching off the heater when all the liquid in the boiling water reservoir has evaporated therefrom;

[E] a condensate trough, defined by the base and thermally insulated from the heater; and

[F] a food tray comprising an imperforate surface and a drainage surface, said food tray supported above the reservoir and trough such that said imperforate surface is aligned with the boiling water reservoir, said drainage surface is aligned with the condensate trough, and water flows from the imperforate surface to the drainage surface into the condensate trough, said reservoir, trough and tray cooperating substantially to prevent the flow of water from the imperforate surface into the reservoir.

Claim 2:

The invention of claim 1 wherein the food tray comprises a surface shaped to facilitate radial drainage to the drainage surface and into the condensate trough.

Claim 3:

The invention in claim 1 wherein the food tray defines a central baffle, vertically aligned with the heater, said baffle operative to direct heated water back to the vicinity of the heater in order to accelerate steam formation.

Claim 6:

The invention of claim 1 wherein the imperforate surface defines a multiplicity of raised surfaces effective to facilitate radial drainage through the drainage surface into the condensate trough.

Claim 31:

A steam cooking utensil comprising:

[A] means for defining a boiling water reservoir;

[B] a heater mounted adjacent a central portion of the reservoir to heat water contained in the reservoir;

[C] means for supporting food to be steamed above the reservoir, said supporting means defining an imperforate surface above the heater; and

[D] a baffle which extends downwardly from the supporting surface over the heater, said baffle shaped to define a partially enclosed region of the supporting surface in alignment with the heater;

[E] said baffle effective to impede the outward flow of water, heated by the heater and splashed by the heater against the partially enclosed region, radially away from the partially enclosed region.

Claims 1 and 31 are independent claims. Claims 2, 3 and 6 are dependent claims, being dependent upon Claim 1.

B. Markman Hearing
On November 18, 1997, this Court held a Markman hearing. See Markman v. Westview Instruments, 52 F.3d 967 (Fed. Cir. 1995) af’d, 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). Markman sets forth a two-step process for resolving patent infringement claims. The first step requires that claim construction (determination of the meaning and scope of the claims) is an issue of law for the district judge to decide. 52 F.3d at 979. The second step is that of the jury looking at the claims and the court-determined definitions in order to determine whether an infringement of the patent took place.

Prior to the Markman hearing, this Court required the parties to brief the type of evidence to be heard at a Markman hearing, to identify any disputed language in the claims, the type of evidence used to resolve any disputes and to offer proposed definitions of the claims. The proposed definitions of both parties greatly assisted this Court during the claim construction phase.

Both Rival and Sunbeam agreed with that only "intrinsic" evidence should be used to construe the disputed claims. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Intrinsic evidence is made up of (1) the claims, (2) the patent specification, and (3) the prosecution history. 6 Markman, 52 F.3d at 979. However, the claims should always be the first place a court looks to determine the scope of the claim. Vitronics, 90 F.3d at 1576.

Extrinsic evidence is anything external to the patent, i.e. expert testimony, dictionaries, technical treatises and articles. Markman, 52 F.3d at 980. Even the plaintiff's product is extrinsic evidence. SRI Int'l v. Matsushita Elec. Corp. of America, 775 F.2d 1107, 1118 (Fed. Cir. 1985). Extrinsic evidence is only to be relied upon to resolve any ambiguity in a disputed claim term. CVI/Beta Ventures, Inc. v. Tura L.P., 112 F.3d 1146, 1153 (Fed. Cir. 1997); Vitronics, 90 F.3d at 1583.

The theory behind the admission of intrinsic evidence, and the exclusion of extrinsic evidence, has been explained by the Federal Circuit 7 in the following manner:

competitors are entitled to review the public record, apply established rules of claim construction, ascertain the scope of the patentee's claimed invention and, thus, design around the claimed invention . . . . Allowing the public record to be altered or changed by extrinsic evidence . . . would make this right meaningless.

Vitronics, 90 F.3d at 1583.
create or form the outline of the shape of the boiling water reservoir.

2. "Thermostat means . . . for switching off the heater when all the liquid in the boiling water reservoir has evaporated therefrom" : a thermostat that automatically switches off the heater when all of the water in the reservoir has boiled dry.

3. "thin" as used in claim 11

Plaintiff's construction: No construction necessary or, having a thickness that is less than the width and length

Defendant's construction: Indefinite

Defendant argues that the term "thin" in "a thin layer of tooth whitening substance" is not defined in the claim language or in the specification and is insolubly ambiguous. As I noted in discussing the term "strip of material," a party that argues that a terms is indefinite bears a heavy burden. It must show that "no narrowing construction can properly be adopted." Exxon Research and Engineering Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001). Although defendant is correct that the term "thin" is not defined explicitly in the patent, the term is not hopelessly ambiguous. At the same time, I agree with defendant that plaintiff's proposed construction has no basis in either the claim language or the specification and I will not adopt it.

The '579 patent is intended to create a product that contains "a non-bulky active containment . . . that will permit the wearer to use the system during social discourse without interfering with the wearer's speech or appearance." '579 Pat., col 1, lns. 26-28. Therefore, the patent reveals that a "thin" layer of "tooth whitening substance" is a layer that does not impede speech or affect appearance. Otherwise, the purpose of the invention would be frustrated. Although this does not offer a precise measurement, it suggests a range of measurements. It is not so broad and infinite that the term is indefinite.

A. Claim Limitation 7(e): "thin membrane having attachable means for attaching said thin membrane to an inner surface of said closure"

Claim limitation 7(e) claims a "thin membrane having attachable means for attaching said thin membrane to an inner surface of said closure." There are two significant aspects to this claim limitation. First, the court construed the phrase "thin membrane having attachable means" to mean "a thin, soft, pliable sheet with a wall around its perimeter. The thin membrane itself may take any of a variety of shapes." Jury Instructions (doc.# 232), at 18. Second, the phrase "means for attaching said thin membrane to an inner surface of said closure" is a means-plus-function claim limitation. The court instructed the jury that "[t]he structure disclosed in the patent specification for performing that recited function is an interlocking snap fit formed by a groove on the exterior of the wall around the perimeter of the thin membrane which abuts and is affixed to a ridge on the interior of the spout." Id.

2. "Thin-walled."

Consistent with the court's previous construction, 21 "thin-walled" is construed to mean "the wall of the tubular member must have little extent from one surface to its opposite at both its first and second diameters."

--- Footnotes ---

3. "Thinner than G-29"

The dispute here is whether the claim language "thinner than G-29" and "[a] needle thinner than a G-29 needle" means all needles thinner than 29 Gauge. Novo argues that this Court should construe the term "thinner than G-29" according to its plain meaning. Becton argues that there is no plain meaning for this claim, because it is an "open-ended range" with no defined upper limit on the needle's thickness. That is, this limitation might read on a 35 gauge needle, a 50 gauge needle, or even a 100 gauge needle, etc., as they are all "thinner than 29 gauge."

Novo's support for this limitation is the originally-claimed 30 gauge needle, and one phrase of a single sentence in Novo's patent which states: "The present invention is based on the surprising recognition that needles thinner than G 29 may be used for injecting insulin." However, this is only a generalized statement referring to a range which cannot be seen as corresponding to the content of the application at that time, because only one single value of this range, G30, has been consistently defined. Construing the patent, this Court comes to the same conclusion as the European Patent Office: that the aim of the application was to use needles thinner than G-29, and the result of this "wish" was the possibility of having a G-30 needle. Only a G-30 needle is allowable in this context. As a result, this Court construes "thinner than G-29" to be thinner than 29 gauge, but not thinner than 30 gauge.

G. Claim 39

A device as in claim 37 wherein the differential expansion portion is thinner than the limited expansion portion.

The parties agree to the construction "a device as in claim 37 wherein the differential expansion portion has comparatively lesser overall thickness than the limited expansion portion."

5. Thread

"Thread" was not one of the terms sought to be construed by either party in the opening claim construction brief; however, defendants now contend it must be construed. Plaintiffs responded to defendants' proposed construction in its responsive brief and at the Markman Hearing.

Plaintiffs construe "thread" as "a yarn or yarns used in forming the stockinette member." It is undisputed that throughout the patent, "thread" is associated with the yarn used for forming the stockinette member. Defendants suggest that "thread" be construed as "yarn comprising cotton, polyester, nylon or other suitable materials, that is finer than the yarn used to form the netting arrangement," contending this construction falls within the "ordinary and customary meaning" of the term within the context of the specification, and is supported by plaintiffs' expert.
As noted in the above discussion of the term "strand," plaintiffs contend that the terms "strands" and "threads" are intended to do nothing more than describe the location of the yarns. "Strand" or "strands" refer to the netting arrangement; "thread" or "threads" refer to the stockinette member. Plaintiffs state they acted as their own lexicographers, which is permissible. But when acting as its own lexicographer, the patentee must set forth an explicit definition of the term different from its ordinary and customary meaning. Phillips, 415 F.3d at 1316. Plaintiffs have not done so here.

Under the ordinary and customary meaning to a person of ordinary skill in the art in question at the time of the invention, "thread" would likely be considered a finer gauge yarn than a strand. This is borne out by plaintiffs' expert's testimony that the threads of the stockinette are finer than the strands of the netting arrangement:

Q. So, I believe you're indicating that a thread and a strand are both yarns, is that correct?
A. Yes, sir.
Q. So how are they different?
A. To me, a thread is finer, a light yarn, a thin yarn.

(Defendants' Exh. F, Mademann Depo. at 66).

Only if plaintiffs made clear they were defining "thread" differently than its ordinary and customary meaning would "thread" not connote a finer gauge yard. Nevertheless, there is no requirement in the claim language or the specifications that require the yarns used to make the netting arrangement be heavier than those used to make the stockinette member which is clear in reference to the second preferred embodiment: "the strands of the netting arrangement are finer than the strands of the netting arrangement:

Q. So, I believe you're indicating that a thread and a strand are both yarns, is that correct?
A. Yes, sir.
Q. So how are they different?
A. To me, a thread is finer, a light yarn, a thin yarn.

(Defendants' Exh. F, Mademann Depo. at 66).

The Court construes "thread" as "a yarn or yarns used in forming the stockinette member."

A. Motion for Reconsideration of Claim Construction

In an Order dated May 14, 1998, this court construed the claims of the '100 Patent as follows: 1). "Boring, when turned, a hole in bone mass" was defined as "making a cylindrical hole by the removal of material with a rotary tool." The court further held that "[a] drill means does not include a screw or a pin or a nail or a trocar tip or any other object that does not have cutting edges and flutes." (Slip Op. at 5-6). "Thread means that includes a plurality of thread flights formed in the anchor distal from said drill means end to turn into the bone mass following the drill means" was defined to include "thread means that overlap the drill means so long as a greater number of thread means are distal from the drill means."
3). "Means for securing a suture to said anchor to extend therefrom after said anchor is seated in the bone mass" was defined as "a structure having a suture permanently attached to a retention disk positioned internally within the anchor." In construing the claim this court relied on the claim itself, the specification and the prior art as revealed in the prosecution history. The court did not rely on extrinsic evidence except for a general understanding of the patent.

Mitek's Motion for Reconsideration of Claim Construction argues that the court committed errors in its construction of the terms "drill means" and "means for securing". Mitek does not request modifications of the court's definition of "thread means". Mitek argues that the question of whether or not a drill means includes a screw, a pin, a nail or a trocar tip is a question for the jury and not a question of law for the court. This court disagrees. Mitek argued and presented evidence at length to support its contention that a drill means includes a trocar tip, a pin, a nail or a screw and requested that this court construe the term "drill means" to include these devices. Only when this court disagreed with Mitek's definition did it argue that this was an issue for the jury. The conclusion that a drill means does not include objects that do not have cutting edges and flutes is fully supported by the intrinsic evidence. Further, the Federal Circuit has affirmed claim construction rulings that define functions or structures that are excluded from the coverage of a claim. See, e.g. The Gentry Gallery, Inc., v. The Berkline Corp., 134 F.3d 1473, 1477 (Fed. Cir. 1998) (term "console" construed to exclude tray unit) and General American
Transp. Corp. v. Cryo-Trans, Inc. 93 F.3d 766, 770 (Fed. Cir. 1996) (opening "adjacent" to a side was construed to exclude opening adjacent to an "end wall").

Mitek further argues that the court committed error in defining "means for securing" to exclude a freely sliding suture. As stated above, this court may properly define functions or structures that are excluded from the coverage of a claim. Mitek also argues that the court may not use the prior art to limit the range of structures that may be equivalent to the structure disclosed in a specification for performing an identified function. Once again, this court disagrees. It is well established that the prior art as cited by the applicant is part of the intrinsic evidence upon which the court must rely to construe the claims. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996). The prior art relied upon by the applicant "gives clues as to what the claims do not cover." Autogiro Co. of America v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 399 (Ct Cl. 1967). The holding that the structure of the means for securing cannot include an eyelet is full supported by the intrinsic evidence. Therefore, Mitek's Motion to Reconsider Claim Construction is denied.

ii. The Shores '786 patent. The Shores '786 patent, which figures so prominently in the prosecution history of the '007 patent, includes the following Figures illustrating the invention:

[SEE FIGURES IN ORIGINAL]

Declaration of Donald I. Chipman, Exhibit C (the Shores '786 patent) at 2. 10.

What is specifically claimed in the '786 patent, as it relates to attempts to overcome this prior art in the prosecution history of the '007 patent, is found in claims 1 through 8:

1. An adjustable peep sight for a projectile launching device, said sight including a housing defining an elongated passage extending therethrough, a pair of thin flexibly resilient and stiff material annular discs mounted from said housing in and transverse to said passage, each of said discs defining a central, generally circular opening formed therethrough and having a plurality of circumferentially spaced, generally radial slits formed therein defining generally radial, inwardly tapering fingers extending inward from the outer marginal portion of the corresponding disc to the central opening therein, said discs being mounted within said passage with said central openings axially registered and the width of said discs at least substantially axially abutted and the slits of one of said discs circumferentially spaced between the slits of the other disc, and wedge means mounted from said housing and adjustably shiftable along said passage, said wedge means including an annular abutment portion disposed in said passage on the side of one of said discs circumferentially spaced between the slits of the other disc, and which means being mounted from said housing and adjustably shiftable along said passage, said wedge means including an annular abutment portion disposed in said passage on the side of one of said discs remote from the other disc and facing and abuttingly engageable with the fingers of said one disc intermediate the opposite ends of the last-mentioned fingers to variably deflect the fingers of said one disc, and thus also the fingers of the other disc, along said passage, responsive to shifting of said wedge means in the direction in which said annular abutment portion faces, said housing including mounting means adapting [sic] said housing to be mounted from a suitable portion of said device.

2. The peep sight of claim 1 wherein said housing is generally cylindrical and said passage extends centrally therethrough, one end of said passage including a counterbore, said discs being seated in said counterbore and removably retained therein by a retaining sleeve removably secured in said counterbore outwardly of said discs.

3. The peep sight of claim 2 wherein said counterbore is threaded and said retaining sleeve is removably threaded in said counterbore.

4. The peep sight of claim 2 wherein the other end of said passage is threaded and said wedge means comprises a sleeve member adjustably threaded in said other end of said passage and said annular abutment portion comprises the end of said sleeve member opposing said one disc.
5. The peep sight of claim 4 wherein the said sleeve member is externally bevelled.

6. The peep sight of claim 4 wherein said sleeve member projects outwardly of the end of said cylindrical housing corresponding to said other end of said passage, and a lock nut threaded on said sleeve member and abuttingly engageable with said housing end.

7. The peep sight of claim 6 wherein said end of said sleeve member is externally bevelled.

8. The peep sight of claim 7 wherein said counterbore is threaded and said retaining sleeve is removably threaded in said counterbore.

The '786 Patent, claims 1-8.

--- End Footnotes ---

iii. Rejection and amendment. The examiner rejected claim 1 of the '007 patent as originally drafted in light of the Shores '786 patent, stating the following:

Shores, Sr. discloses a peep sight for an archery bow, comprising a base 28 a plurality of sight inserts 38, 40, 42, and 44. The insert 44 is selectively mountable in a prescribed position on the base 28 and defines a sight opening for the user to align with a front sight pin when aiming an arrow. The sight includes a releasable locking means 50 for locking the threaded insert 44 against rotation within the threaded base opening 30. The above described device of Shores, Sr. provides all of the structure recited in [application] claims 1, 2 and 4.

As to claim 3, the inserts 38, 40, 42 and 40 in the device of Shores Sr. each have different sized openings and have the capability to be used selectively under different field conditions to vary the size of the sighting aperture.

In response to this rejection of application claims 1 through 4, the applicants for the '007 patent filed an amendment on December 16, 1991, amending claim 1, in pertinent part, to include a limitation that the base member have "an internally threaded opening therethrough aligned with the sighting path when the bowstring is drawn for shooting, said threaded opening having a first prescribed diameter so that the user can sight through said threaded hole in low light conditions" and a limitation for "a plurality of externally threaded interchangeable sight inserts interchangeably and selectively mountable [in] to a prescribed sight position. . . ." Id. at 47 (underlining showing additions, brackets showing deletions). In support of the patentability of application claims 1 through 4, as amended, the applicants asserted the following:

The Examiner rejected Claims 1-4 under 35 U.S.C. § 102(b) as being anticipated by Shores, Sr. Claim 1 has been amended to specify that the inserts are interchangeable with the threaded opening through the base serving to as [sic] one sighting opening and with each of the inserts having a different size opening so that the size opening being used is determined by selecting the particular insert or the base member with the desired size opening and using it. This [is] quite unlike Shores, Sr. where the pieces must be screwed together to get the right size opening and the user must guess at the actual size opening that has been adjusted in that sight. While it is true that each of the members 38, 40, 42 and 44 each have a different size opening therethrough but [sic] it is respectfully pointed out that only the openings in members 38 and 40 serve to establish the variable sight opening. Thus, Shores, Sr. teaches just the opposite of the claimed structure, that is, the use of one set of members in the sight rather than interchangeable separate members and the use of a variable size sight opening rather than different fixed size sight openings in the different inserts. Therefore, it is submitted that Claim 1 is clearly patentable over the prior art.

Id. at 51. This prosecution history establishes that both the "threading" and the "interchangeability" limitations, which Kudlacek contends are absent from his device, were offered in an amendment seeking to obtain patentability over the Shores '786 patent. After this amendment, the examiner issued a Notice of Allowability for the '007 patent application on March 6, 1992, allowing amended claim 1. Id. at 56. Therefore, the critical question is, whether (and which parts) of the amendments were directed to distinguishing claim I of the '007 patent from the Shores '786 patent? See Fiskars, Inc., 221
iv. The scope of prosecution history estoppel. The '786 patent says nothing whatever about "a plurality of externally threaded interchangeable sight inserts," each of which "defines a [different] sight opening." Compare The '007 Patent, claim 1, with The Shores '786 Patent, claims 1-8 (supra, n.10). Rather, the '786 patent relies on a single threaded insert, or "wedge means" (44 & 46) that varies the size of the sighting window when it is "adjustably shifted along" the passage in the central cylinder (28), thereby deflecting the "fingers" (54) of the internal "discs" (38 & 40) a greater or lesser amount. See The '786 Patent, claim 1; see also The Shores '786 Patent, Fig. 3, supra at 106. However, the examiner for the '007 patent described both the "discs" (38 and 40 in the figures to the Shores '786 patent) and the "wedge means" (44 in the figures to the Shores '786 patent), as well as the "retaining sleeve removable secured in said counterbore outwardly of said discs" (42 in the figures to the Shores '786 patent), see The Shores '786 Patent, claim 2 (defining the "retaining sleeve" limitation), as constituting "a plurality of sight inserts." See Prosecution History File of The '007 Patent at 39-40 ("Examiner's Action" of September 16, 1991). The examiner for the '007 patent also described these "inserts" in the Shores '786 patent as "each having different sized openings and having the capability to be used selectively." Id. at 40. The examiner also noted that both the "insert 44" and the "base opening 30" were "threaded." See id. at 39.

Indeed, in their argument in support of the patentability of amended application claim 1, the applicants did not argue that the addition of the "threading" language was what made the amended claim patentable over the Shores '786 patent. The applicants' arguments for the patentability of the amended claim mention only in passing "threading" of the inserts and base member of their device, just as they mention only in passing that the parts of the device in the Shores '786 patent are "screwed together." See Prosecution History Of The '007 Patent at 51. In contrast, as Specialty argues, the applicants expressly argued that the "interchangeable" feature established the patentability of amended application claim 1. See id. The applicants expressly argued that "claim 1 has been amended to specify that the inserts are interchangeable with the threaded opening through the base," so that different size sight openings could be used under different conditions. See id. (emphasis added). The applicants explained that "this [is] quite unlike Shores, Sr. where the pieces must be screwed together to get the right size opening and the user must guess at the actual size opening that has been adjusted in that sight," because "Shores, Sr. teaches just the opposite of the claimed structure, that is, the use of one set of members in the sight rather than interchangeable separate members and the use of a variable size sight opening rather than different fixed size sight openings in the different inserts." Id. (emphasis added). The applicants acknowledge that, "while it is true that each of the members 38, 40, 42 and 44 [of the Shores '786 patent] each have a different size opening therethrough . . . it is respectfully pointed out that only the openings in members 38 and 40 serve to establish the variable sight opening." Id. The court concludes, in light of the examiner's grounds for rejection of the original claim and the applicants' arguments for patentability of the amended claim, that only the "interchangeability" amendment, not the "threading" amendment was directed to distinguishing the claim or claims of the patent-in-suit from the Shores '786 patent reference, and thus only the "interchangeability" amendment gives rise to any prosecution history estoppel as to claim 1. See Fiskars, Inc., 221 F.3d 1318, 2000 WL 1015080 at * (not every amendment gives rise to estoppel; amendments not directed to patentability do not give rise to estoppel).

This does not mean, however, that the "threading" language in the '007 patent is irrelevant to the construction of claim 1. Rather, "the central focus of the infringement analysis remains on the claim language," albeit claim language "as illuminated by the written description and the prosecution history." See KCJ Corp., 223 F.3d 1351, 2000 U.S. App. LEXIS 20963, *8, 2000 WL 1165522 at *3; Tate Access Floors, Inc., 222 F.3d 958, 2000 WL 1055981 at *4; Hockerson-Halberstadt, Inc., 222 F.3d at 956, 2000 WL 1035753 at *2; Optical Disc Corp., 208 F.3d at 1334. Indeed, "the claim language . . . defines the bounds of claim scope." Schering Corp., 222 F.3d 1347, 2000 U.S. App. LEXIS 18360, *13, 2000 WL 1055975 at *5 (quoting York Prods., Inc., 99 F.3d at 1572). Here, the limitations of claim 1 of the '007 patent expressly and unambiguously claim "threaded" inserts and a "threaded" base member. See The '007 Patent, claim 1. To ignore this "threading" language would be to read an express limitation out of the patent. 11 Thus, such "threading" is literally required by the patent...
language, although the prosecution history does not exclude non-threaded "equivalents" under the doctrine of equivalents. Moreover, the court notes that this identical "threading" of the hole in the base member and the exterior of the inserts is also indicated in the specification of the preferred embodiment in the '007 patent. See, e.g., The '007 Patent, "Detailed Description Of Illustrative Embodiments," at Col. 3, ll. 10-11 (the hole in the base member is "threaded with threads for use in mounting the inserts"), ll. 17-18 ("The insert 16 is externally threaded with threads 30 complementary to the hole threads 26"). Thus, to the extent that the specification of the preferred embodiment of the invention in the patent "illuminates" claim language, See KCI Corp., 223 F.3d 1351, 2000 U.S. App. LEXIS 20963, 2000 WL 1165522 at *3; Tate Access Floors, Inc., 222 F.3d 958, 2000 WL 1055981 at *4; Hockerson-Halberstadt, Inc., 222 F.3d 951, 2000 WL 1035753 at *2; Optical Disc Corp., 208 F.3d at 1334, the specification here confirms that the patented device literally requires "threading" of the hole in the base member and the exterior of the inserts.

11 This express statement of a particular structure in the claim itself in the '007 patent should be contrasted with the lack of any such specification of the number of parts that make up the "adjustment member" as defined in claim 1(d) of the '325 patent. As to claim 1(d) of the '325 patent, the court refused, above, to "read into" the patent a requirement that the claimed "adjustment member" had to be a single piece, even though the preferred embodiment indicated more narrowly that the "adjustment member" was a single piece, because it is improper to read narrower language from a description or specification into broader claim language. See KCI Corp., 223 F.3d 1351, 2000 U.S. App. LEXIS 20963, 2000 WL 1165522 at *4. As to the '007 patent, the court declines to "read out" of the patent a "threading" requirement specified in the claim language. The court notes that the specification of the preferred embodiment and the "threading" limitation in claim 1 of the '007 patent describe identical structures, rather than a preferred embodiment that is narrower than claim language. See, e.g., The '007 Patent, "Detailed Description Of Illustrative Embodiments," at Col. 3, ll. 10-11 (the hole in the base member is "threaded with threads for use in mounting the inserts"), ll. 17-18 ("The insert 16 is externally threaded with threads 30 complementary to the hole threads 26").

v. The resulting construction. In short, as to construction of the challenged portions of claim 1 of the '007 patent in light of prosecution history estoppel, the court concludes that the claim must be construed as literally requiring a base member with "an internally threaded opening therethrough" and "a plurality of externally threaded interchangeable sight inserts interchangeably and selectively mountable to a prescribed sight position in and substantially filling said threaded opening in said base, each of said sight inserts defining a sight opening therethrough." The '007 Patent, claim 1. Only equivalents of the "interchangeability" element are limited by the prosecution history of the patent; there is no such limit on the "threading" elements.

c. Construction of "threaded"

The court's construction of the claim is not finished, however, because the meaning of "threaded" must be construed, in light of Kudlacek's contention that his accused device has no threads and Specialty's contention that Kudlacek's base member has "one large thread." Even though the parties dispute the applicability of "threaded" to Kudlacek's peep sight, they do not dispute that "threaded" must be given its "ordinary meaning" in the '007 patent, nor do they dispute what that "ordinary meaning" is. Therefore, the court must briefly consider the "ordinary meaning" of "threaded" as it relates to the internally threaded hole in the base member and the externally threaded sight inserts claimed in claim 1 of the '007 patent.

As the parties apparently agree, there is no novel definition of "threaded" expressly stated in the '007 patent. Thus, the court must rely on the "ordinary meaning rule" to determine the proper construction of this term. See, supra, p. 37ff. The pertinent dictionary definition, for present purposes, of "thread," as a noun, is "a projecting helical rib (as in a fitting or on a pipe) by which parts can be screwed together: SCREW THREAD," while the pertinent definition of "thread," as a verb, is "to form a screw thread on or in." MERRIAM WEBSTER'S COLLEGIATE DICTIONARY (10th ed., 1995). The dictionary definitions proffered by the parties are comparable. Specialty, for example, proffers the definition of "thread" as a "helical or spiral ridge," citing AMERICAN HERITAGE DICTIONARY (2d ed.), and Kudlacek embraces that definition. "Helical" in turn means "of, relating to, or having the form of a helix; broadly: SPIRAL"; where "helix" is defined as "something spiral in form," such as "a coil formed by winding wire around a uniform tube," or "a curve traced on a cylinder or cone by the rotation of a point crossing its right sections at a constant oblique angle; broadly: SPIRAL"; and where "spiral" itself, as a
noun, is defined as "the path of a point in a plane moving around a central point while continuously receding from or approaching it," and as "a three-dimensional curve (as a helix) with one or more turns about an axis."

The court concludes that Specialty has ignored the "helical" or "spiral" meaning of "thread" and the meaning of the term that indicates that complementarily "threaded" parts must "screw" together by asserting that the patent term encompasses parallel ridges that form complete circles or segments of a complete circle. However, the court concludes that "threaded," "threads," and "threading" in the '007 patent, according to the ordinary meaning of the terms, require that the "threaded" parts have a continuous helical or spiral ridge or groove, around the inside of the hole in the base member (i.e., internally), or around the outside of each sight insert (i.e., externally), completing one or more turns around the central axis of the part, like the threading of a nut or bolt, respectively, and parts with complementary threads must be able to "screw" together.

4146
H. "End"

Mitek argues that the term "end" in the following clause in claim 1, "threaded back end" should be construed to mean the extreme or last part lengthwise. Mitek argues that the patent does not cover implants that have a head at the end. Mitek cites to the language in the Preferred Embodiments that the "[i]mplant 40 has a threaded proximal end and a threaded distal ends." (Doc. 140, Exh. 1 4:51). Arthrex argues that there is no support for Mitek's request to limit the implant to those that do not have a head at the end, and that this patent is directed to a method of ACL surgery and not to a specific type of implant used in that method.

In the Summary of the Invention, the patent provides that the "implant preferably is formed with back-biting threads: Accordingly, the implant easily can be impact driven into the repair site, and yet can be removed if necessary by rotation." (Doc. 140, Exh. 1, 3:6-9). The Preferred Embodiments provides that the implant "can be driving by impaction into bone, and then, if necessary can be subsequently removed by screw rotation as discussed below." (Doc. 140, Exh. 1, 4:60-62). The Court finds no language in the claim or the specification which limits the type of screw end. Relying on the language of the claim and the language in the specification, the Court determines that a "person of ordinary skill in the art" would construe the "ordinary and customary meaning" of the terms "threaded back end," to mean either a screw with or without a head that has a threaded back part.

GO BACK

4147
D. Three Dimensional Position

The parties present nearly identical definitions for "three dimensional position." Scanner asserts that the term refers to "the X, Y and Z values for the top of at least one ball of a ball grid array." (Scanner Post-Hr. Br. at 13). ICOS asserts the following definition: "the determination of the actual X, Y and Z coordinate positions of the balls." (ICOS Post-Hr. Br. at 23). Because these definitions are similar, it is apparent that the parties do not genuinely dispute the definition of the term as it applies to the patents at issue. The Court adopts the definition set forth by Scanner. Accordingly, for the purposes of this case, "three dimensional position" is defined as "the X, Y and Z values for the top of at least one ball of a ball grid array."

GO BACK

4148
The principal dispute at the Markman hearing concerned the proper construction of the term "3-end knit," which appears in claims 1 and 6 and their dependent claims. Southern Mills proposed that the term be construed to mean a "fabric containing yarns capable of serving one of three different functions in the fabric." That definition, Southern Mills contended, would include the use of either one, two, or three different yarns, as long as the yarns used in the fabric were collectively capable of performing the stitch, tie, and nap functions. Polartec argued for a narrower definition that would require the use of three different yarns, with each yarn performing only one of the specified functions.
The district court found the claim language to be inconclusive and accordingly looked to the specification. After conducting a detailed review of the specification, the court adopted Polartec's requested definition and construed "3-end knit" to mean "a knit formed of three different yarns, each serving one of three different functions: stitch, tie, and nap." The court explained that "[t]he very first sentence of the Detailed Description section reads: 'The 3-end knit structure comprises the interaction of three yarns each serving their own function.'" Moreover, the patent described the stitch yarn as being "the only yarn of the three that is visible from the face side of the cloth." The court noted that for each of the three functions, the patent provides a separate list of suggested materials and types of yarn, indicating that the patent contemplates the use of three different yarns in the knit structure.

The district court next construed the three different yarn functions. The court ruled that "stitch yarns" form the face side of the knit and are the only ones visible from the face side; that "tie yarns" attach the nap yarns to the back side of the knit and are not visible from the face side; and that "nap yarns" lie on the back side of the knit, are tied into the knit at periodic intervals by the tie yarns, and are not visible from the face side of the knit. The court based its construction on language in the claims as well as the specification. In particular, the court observed that claim 1 states that the "stitch yarns form the face side of the fabric," and that the "nap yarns are tied into the knit at periodic locations along the back side of the fabric by the tie yarns." See '401 patent, col. 5, ll. 59-62. The court also relied on language from the specification stating that "[t]he stitch or face yarn . . is the only yarn of the three that is visible from the face side of the cloth," and that "[t]he nap yarn . . . is attached to the knit by the tie or tie-in yarn which is not visible from the face side of the fabric." Id., col. 3, ll. 49-51, 65-67. The court added that its earlier construction of "3-end knit" foreclosed the argument that a single yarn could be used to perform both the stitch and the tie functions such that the tie yarn would also be visible from the face side.

After the court issued its claim construction order, the parties agreed that Southern Mills could not prove infringement under the claims as construed. The parties therefore consented to entry of a judgment of noninfringement so as to enable Southern Mills to obtain review of the court's claim constructions.

II

Southern Mills argues that the district court erred in limiting the invention to a knit formed of three different yarns. It contends that the portions of the specification that require the use of three different yarns represent only a preferred embodiment, and that a person skilled in the art would understand the patent to claim fabrics using fewer than three yarns.

A

The main thrust of Southern Mills' appeal is a challenge to the district court's claim constructions as applied to claims 1 and 6. Those claims and their dependent claims all recite that the claimed fabric is a "3-end knit." The specification defines a "3-end" fabric as a two-sided fabric that includes "a knit formed of a stitch yarn and a tie yarn, wherein the stitch yarn lies on the fabric face side. A nap yarn lies on the back side of the fabric and is tied into the knit at periodic intervals." '401 patent, col. 2, ll. 41-44. The specification adds that to manufacture the 3-end fabric, "a knit is formed of the stitch yarn, the tie yarn, and the nap yarn." Id., col. 2, ll. 56-58.

Southern Mills contends that the "3-end knit" does not require the use of three different yarns, as long as it consists of "yarns capable of serving one of three different functions." In so arguing, Southern Mills relies on the statement in the specification that "[t]he term '3-end' means that yarns serve one of 3 different functions in the fabric." '401 patent, col. 2, ll. 35-36. While it is true that the yarns must perform those three functions, it is also evident from the specification that those three functions are performed by three different yarns. That much is plain from the language of the specification that describes the 3-end knit structure as comprising a stitch yarn, a tie yarn, and a nap yarn, and from the repeated references in the specification to the stitch, tie, and nap "yarns" rather than "functions."

Perhaps the clearest statement to that effect is at the beginning of the Detailed Description section of the patent, where the specification states: "The 3-end knit structure comprises the interaction of three yarns each serving their own function." '401 patent, col. 3, ll. 22-23. Other statements in the specification make the same point. For example, the portion of the specification that describes the 3-end knit structure states that the "stitch or face yarn" is "the only yarn of the three that is visible from the face side of the cloth." Id., col. 3, ll. 65-67. That statement implies that the 3-end knit structure comprises three yarns, not one or two yarns that perform the three functions. As another example, the specification describes in detail the different preferred composition and weight of each of the yarns, id., col. 4, ll. 25-36, providing another indication that
the 3-end knit structure contemplates the use of three separate yarns.

Southern Mills attempts to downplay the significance of those statements from the specification by characterizing them as merely descriptions of a preferred embodiment, which therefore do not limit the meaning of "3-end knit." The characterizations of "3-end knit" in the specification, however, are distinctly definitional; they do not purport to describe one or more variants of a 3-end knit, but rather set forth what the patentee regarded as the meaning of the term "3-end knit" as used in the claims.

In support of its proposed construction of "3-end knit," Southern Mills relies principally on a sentence in the specification that refers to a "2-end fleece" pattern. In the course of describing a preferred embodiment of the 3-end knit structure, illustrated by Figure 1 of the patent, the specification states that "[t]he knit pattern shown in Fig. 1 is called a 3-end fleece pattern. Other patterns can be used, such as a 2-end fleece or a terry-cloth, for example." '401 patent, col. 4, ll. 48-51.

According to Southern Mills, that language reflects a distinction between "pattern" and "structure." The term "3-end fleece pattern," Southern Mills argues, refers to a fabric in which three yarns perform the three designated functions of the stitch yarns, tie yarns, and nap yarns, while "2-end fleece pattern" refers to a fabric in which two yarns perform those three functions. By contrast, the term "3-end knit structure" contemplates the use of yarn to perform the three designated functions, but does not require the use of three different yarns to do so. As interpreted by Southern Mills, the reference to "2-end fleece pattern" thus indicates that neither the patent as a whole, nor those claims that require a "3-end knit," require the use of three different yarns.

We agree with the district court that Southern Mills' argument regarding that passage of the specification is unpersuasive. The terms "2-end fleece" and "terry-cloth" are used only once in the patent and are not defined. Southern Mills makes no attempt to explain the meaning of the reference to terry-cloth; as to the term "2-end fleece," Southern Mills relies on the testimony of Dr. Adanur, its expert. Dr. Adanur's testimony, however, does not provide persuasive support for Southern Mills' position. As the district court explained, Dr. Adanur expressly acknowledged that the term "2-end" has no recognized meaning in the field of technical textiles. He simply asserted that, within the context of the '401 patent, the term has the meaning advocated by Southern Mills. Moreover, when he was directed to language in the specification that was contrary to his interpretation of the term "3-end," his response on each occasion was that the language in question referred to a preferred embodiment. As such, Dr. Adanur's testimony was unhelpful because it constituted only a recitation of how he would construe that term, not an explanation of its "accepted meaning in the field" to one skilled in the art. Symantec Corp. v. Computer Assocs. Int'l, Inc., 522 F.3d 1279, 1290-91 (Fed. Cir. 2008); see also Phillips v. AWH Corp., 415 F.3d 1303, 1318 (Fed. Cir. 2005) (en banc) ("'[C]onclusory, unsupported assertions by experts as to the definition of a claim term are not useful to a court."). Because the specification repeatedly makes clear that the 3-end knit structure requires three yarns to perform the three designated functions, it would be speculative to conclude that the unelaborated reference to a "2-end fleece" pattern teaches an embodiment of the 3-end knit structure that uses fewer than three yarns.

Southern Mills also relies on a statement in the Summary of the Invention that the yarns employed in the manufacture of the claimed fabric "may all be the same, but the 3-end structure allows the selection of the best yarn for each of the three functions: stitch, tie, and nap." '401 patent, col. 2, ll. 36-39. As the district court concluded, the most reasonable interpretation of the phrase "may all be the same," particularly in light of the remainder of the sentence in which the phrase appears, is that it refers to the type of material to be selected for each yarn, not to whether more than one of the yarn functions may be performed by a single yarn.

Accordingly, we conclude that the district court was correct in its construction of the term "3-end knit." We therefore affirm the district court's judgment as to asserted claims 1 and 6, and their asserted dependent claims.

Through

Arcom objects to Magistrate Judge Peebles' recommended construction of the term "through" as used in Claims 23 and 25 to describe the bore through the insulator member and the conductor extending through the bore. Magistrate Judge Peebles recommends that the term "through" in these contexts be construed as "traversing an element from one end to the other." Arcom argues that it should be construed as "traversing an element partially or completely."
As noted by Magistrate Judge Peebles, modifiers to the term "through" are used in the claims when something less than complete traversal of an element is intended. For example, Claim 23 claims an insulator member "extending through at least a portion of the passageway of the female connector" (emphasis added). And Claims 15 and 18 claim an insulator member extending "through substantially the entire length of the female connector"  (emphasis added). Thus, Magistrate Judge Peebles' recommended construction is supported by the general principle that a claim term "should be construed consistently with its appearance in other places in the same claim or in other claims of the same patent." Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed.Cir. 2001).

Arcom's other arguments are not persuasive. In particular, the Court agrees with Magistrate Judge Peebles' rejection of Arcom's contention that the recommended construction excludes the preferred embodiment. On de novo review, the Court adopts Magistrate Judge Peebles' recommended construction.

GO BACK

IV.

Like the other patents-in-suit, Devon's '592 patent relates to a receptacle for disposing of expendable items, such as hazardous medical waste, without allowing a user to contact previously accumulated waste. Figure 1 of the '592 patent illustrates the claimed features.

[SEE ILLUSTRATION IN ORIGINAL].

A container 10 has two baffles 11 and 12 that are used to close the container. Each baffle 11 or 12 has an opening 15 or 16 through which expendable items, such as used syringes, can be deposited. As discussed below, the claim requires that the openings be horizontally offset from one another to minimize the chance of a user coming into contact with previously deposited waste.

Claim 1, the only independent claim of the '592 patent, reads (with emphasis to highlight disputed limitations):

1. A receptacle for receiving expendable items, said receptacle including a container, a first baffle generally closing the top of said container and defining a first opening through said first baffle of such size and shape to receive said expendable items therethrough, a second baffle disposed below said first baffle, said second baffle defining a second opening therethrough of such size and shape to receive said expendable items, said second opening being horizontally displaced from said first opening, said first baffle and said second baffle defining a space therebetween sufficient to allow said expendable items to pass through said first opening, between said first baffle and said second baffle, and through said second opening to be received within said container.

For purposes of summary judgment, the parties have focused their dispute on the highlighted portions of the claim, specifically, the requirements (1) that the first and second openings pass "through" the first and second baffles, and (2) that the first and second openings be horizontally displaced from one another so that deposited waste travels laterally as it passes through the space between the two baffles. On these points, the district court properly interpreted the claims.

First, the claim requires that the first and second openings pass "through" the first and second baffles. The district court properly construed this term to mean that each opening extends from one side of the baffle to the other. See Webster's Third New International Dictionary (1981) (defining "through" as "into at one side or point and out at another, especially the opposite side of") (quoted by district court). Although there are other possible meanings for "through," including one cited by Devon that means something more like "allowing passage," these definitions are not used in connection with an "opening through" another structure, such as a baffle. Thus, the ordinary meaning of the claim term "through," which controls in the absence of an extraordinary usage by the patentee, see York Prods., 99 F.3d at 1572, 40 U.S.P.Q.2D (BNA) at 1622, requires that the first and second openings pass from one side of each baffle to the other.

The written description confirms this straightforward construction of the claim language. There, the patentee shows openings that pass "through" the baffles -- that is from one side of each baffle to the other. See '592 patent, figures 1-6. Also,
in describing the operation of the claimed receptacle, the written description says that "an item can be placed through the opening 15 as shown by the arrows [in Figure 3]." See id., col. 3, lines 39-41. The arrows shown in Figure 3 demarcate a path passing from one side of baffle 15 through the baffle to the other side of baffle 15. Finally, the written description also teaches forming the openings by "cutting" the baffle. See id., col. 3, lines 1-2. Such "cutting" would not be needed if, as Devon avers, "through" merely meant "past."

Finally, the prosecution history does not show any unique usage of the word "through" that would contradict its plain meaning. Rather, during the prosecution of the application leading to the '592 patent, the applicant referred to each baffle as a "flap having a hole therethrough." Amendment, filed August 3, 1981, p. 3 (emphasis added). That is, the applicant used the word "hole" as a synonym for "opening," thereby clearly indicating that an "opening through [a] baffle" extends from one side of the baffle to the other.

The parties also disagree about the meaning of "extend through." Osteonics maintains that extend through must mean that the rod passes the entire length of the isthmus of the femur. DCW replies that it need not extend all the way through. This particular dispute is harder to resolve; definitions of "through" typically imply the "penetration" or "passage within" another object, see Webster's Third New International Dictionary 2384 (G. & C. Merriam Co. 1981) and, in conjunction with the word "extend," would probably admit of either interpretation. Yet when viewed in conjunction with the claim's requirement that the central long axis of the femur passes through the central long axis of the inserted rod portion, the claims seem best understood along the lines Osteonics suggests.

The term "flow of said paint through said passageway, to said nib" appears in claim 1 and claim 12. Chip-Mender argues that the term means "flow of said paint through said channel to, not through, said nib." Sherwin-Williams asserts that it means "flow of paint through said passageway and to said nib. The paint may then travel through and/or around the nib in being transferred to the painted surface of a vehicle."

The parties do not dispute the plain meaning of "flow of said paint through," and while Chip-Mender defines "passageway" as "channel," and Sherwin-Williams stays with the original "passageway," the distinction between "passageway" and "channel" is not a point of contention. The only dispute is whether "flow… to said nib" means "flow… to, not through" the nib, or "flow… to said nib [and] then… through and/or around the nib."

Chip-Mender argues that "to the nib" means exactly what it says, and that defining "to the nib" as "to and/or through the nib" would be inconsistent with the claims and the specification of the '299 patent, because it might suggest that the claimed "nib" could be porous or that paint could flow "through" it. Chip-Mender also contends that the wording of the claim elements is controlling—noting that when the patent applicant meant "through," he said "through," not "to" (e.g., specifying "through said passageway" in element (d) of claims 1 and 12, rather than "to said passageway").

Chip-Mender asserts further that the language of element (e) of claim 12--"allowing it to open"--indicates that the nib must be non-porous, because something that is porous is already "open" by definition, and need not be "opened" to allow paint to flow. Thus, Chip-Mender argues, the nib must be non-porous in order that it can be "opened" to allow the paint to flow. Accordingly, nothing can flow "through" it. Chip-Mender asserts that the fact that the nib must be able to open and must regulate paint flow is established throughout the specification of the '299 patent (citing '299 patent, col. 2, II. 8-12, a description of the nib serving "as a regulator of the flow rate of paint composition"). Chip-Mender notes that the phrase "to the nib" appears repeatedly in the specification, without a single suggestion that what is really meant is "through the nib."

Finally, Chip-Mender points again to its cancelled claims 23-26, referring to the claim limitations "mov[ing] said nib from closed position to open" and "method of using sealed paint applicator." Chip-Mender also contends that its related Canadian
The patent explains in its abstract that the patent discloses "[a] paint applicator system utilizing a paint reservoir which is connected to a moveable nib which permits paint to pass through the reservoir to the exterior of the nib…. said nib serving to start and stop the flow of paint composition out of the reservoir, through the output end of the passageway onto the painted body."

In opposition, Sherwin-Williams relies on dictionary definitions of "to" from the American Heritage Dictionary--"in a direction toward; so as to approach or come near; in the direction of, so as to reach or terminate in; reaching as far as; through or terminating in"--and argues, based on these definitions, that the ordinary meaning of "to" does not exclude "through." Sherwin-Williams claims, for example, that driving "to" San Francisco does not exclude driving "through" San Francisco. Sherwin-Williams also argues that even if "to" does not expressly include "through," as in the idiomatic phrase "rotten to the core," the word "to" clearly does not exclude paint flowing "through" the nib. Sherwin-Williams contends that "to said nib" does not limit paint flow after the paint reaches or comes into contact with the nib, arguing that the claim term requires only that paint flow through the passageway and to the nib, with no limitation as to whether the paint also travels through and/or around the nib in being transferred to the painted surface.

Sherwin-Williams argues further that "open" in claim 12 does not define "nib" as solid, and that in any event, the term "open" can be applied to applicators with fibrous or porous nibs. Sherwin-Williams contends that it is the applicator that is "open" in claim 12, not the nib, but that even if Chip-Mender is correct that a porous nib is always "open," that would mean that a solid nib is always closed and could never be "open," and claim 12 could never be infringed by a solid nib.

Sherwin-Williams also asserts that the descriptions in the specification of a nib that "serves as a regulator" or that "tends to seal" are preferred embodiments that appear either in the "Preferred Embodiments" section of the specification, or following the "preferably constructed" language in the specification. Sherwin-Williams claims that none of the terms that Chip-Mender cites as support for its "solid nib" appear anywhere in the claim language--"regulator," "tends to seal," "sealed paint applicator," or "moved said nib from closed to open position." Sherwin-Williams argues that all these are terms that the inventor could have used in the claims but chose not to, and asserts that the court must construe the claims as written, not as the patentee wishes he had written them.

Finally, Sherwin Williams argues that cancelled dependent claims 23-26 and the Canadian patent preclude either a solid nib or a seal. Sherwin-Williams Claims that the fact that claims 23-26 specifically claimed a seal, but did not issue because they were cancelled, supports the proposition that Chip-Mender forever abandoned the ability to have claims limited to just a sealed applicator. Sherwin-Williams argues that these cancelled claims serve to emphasize that a seal or solid nib could have been, but were not, specified in the claims. Sherwin-Williams claims that under either the doctrine of claim differentiation or the common law doctrine of expressio unius est exclusio alterius, 5 solid or sealed nibs are not specified or required in the patent.

Footnotes

4 Under the doctrine of claim differentiation, two claims of a patent are presumptively of different scope. Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1366 (Fed. Cir. 2000). It isn't clear (and Sherwin-Williams does not elucidate) how the doctrine of claim differentiation applies here with regard to cancelled claims 23-26.

5 This "maxim of interpretation" holds that "to include or express one thing implies the exclusion of the other, or of the alternative…. For example, a rule that 'each citizen is entitled…' implies that noncitizens do not share in the entitlement." Bryan A. Garner, A Dictionary of Modern Legal Usage (Oxford, 2d ed., 2001). Sherwin-Williams does not explain how this maxim applies here.

End Footnotes

The court finds that "flow of said paint through said passageway, to said nib" means "flow of said paint through said channel to, not through, said nib." The central argument between the parties with regard to this claim term involves whether the paint flows "through" the nib.

There is no support anywhere in the patent for a construction of "to the nib" as meaning "through the nib." The court notes in particular that where the patentee meant to say "through" in the claims, as in "through the passageway," he said
"through." See '299 patent, col. 5, ll. 35-39; col. 6, ll. 17-20 ("flow of said paint through said passageway, to said nib"). Similarly, the specification describes the paint flowing "from the reservoir to the passageway and outwardly from the housing at the nib." Id., col. 2, ll. 9-10. This indicates that the paint flows from the reservoir to the passageway, then continues to the nib--i.e., through the passageway. Once it reaches the nib, flows "outwardly" from the housing.

The preferred embodiment is also consistent with this construction of "to the nib." "[W]hile it is of course improper to limit the claims to the particular preferred embodiments described in the specification, the patentee's choice of preferred embodiments can shed light on the intended scope of the claims." Astrazeneca AB v. Mut. Pharm. Co., 384 F.3d 1333, 1340 (Fed. Cir. 2004). A patent applicant need not expressly state "my invention does not include X" to indicate his exclusion of X from the scope of his patent. Id.

The "Detailed Description of the Preferred Embodiments" section of the '299 patent describes the operation of the paint applicator unit shown in Fig. 2 as follows:

A passageway 28 is included which permits the paint composition 24 to flow from reservoir 22 to chamber 30, and to a nib or stylus 32 is slidable within chamber 30 and biased downwardly by spring 34 into such a position, nib 32 tends to seal opening 20 to chamber 30. However, when an upward force is applied to the tip of nib 32, force arrow 36, nib slides upwardly and allows paint composition 24 to flow from reservoir 22, through passageway 28 and chamber 30 and outwardly from housing 18, arrows 38 and 40.

This preferred embodiment describes the paint flowing down through the passageway, to the nib and "outwardly" from the housing.

The primary dictionary definition of "to"--"in a direction toward; so as to approach or come near--is the only definition that is consistent with the intrinsic record. While "to" has literally dozens of meanings--depending on the semantic context or the syntactical structure of a given phrase--when used in conjunction with a verb that expresses movement or action (such as "flow"), it does not have the same meaning as "through." The word "to" when used with a verb that expresses movement (such as "flow") means "in a direction toward." See, e.g., Websters II New Riverside University Dictionary. "Through," on the other hand, which also has dozens of meanings, generally signifies "in one side and out the other side of or "in the midst of" or "by means of." Id.

The second step of Claim 13 recites:

(2) passing an amount of detergent solution through said wash load in excess of that necessary to saturate the wash load without mechanically agitating said wash load.

The parties dispute the meaning of "passing . . . through said wash load." Whirlpool contends that "passing an amount of detergent solution through said wash load should be construed as "spin washing the wash load by forcing an amount of detergent solution through the wash load by centrifugal force." Defendants contend that the ordinary meaning applies, i.e., that "passing through" requires the solution to pass "through" the clothes, but not over or around them. Passing through refers to a path that goes in one side of the clothes and out another.

With respect to this step, the specifications provide as follows:

Step 72 is to apply the concentrated detergent solution to a spinning wash load. This is referred [sic] to as the spin wash cycle in that the clothes load is not mechanically agitated, it merely is spun with the wash basket and held by centrifugal force against the basket wall during the spinning while the concentrated solution is applied to the spinning wash load.
'666 Patent, col. 5 ll. 35-41.

[D]uring the spin wash step 72 . . . spin speeds in the range of 420-640 RPM are desirable in order to cause the detergent solution to quickly and directly pass through the clothes load . . . .

[F]orcing the water through the fabric by centrifugal force causes it to take a relatively direct (radial) path through the fabric, as opposed to following a path of least resistance . . .

Whirlpool's definition of "passing . . . through said wash load" adds the concepts of spin washing, forcing, and centrifugal force. These concepts are found in the specifications and in Claim 8, but they are not are not found in Claim 13. Claim 13 simply recites "passing an amount of detergent solution through said wash load." The additional concepts Whirlpool introduces in its proposed construction are not justified by the language used in the claim.

Defendants' proposed construction, which requires the detergent solution to pass "through the wash load, not over or around it," (Def. Claim Constr. Br. at 18), is more true to the claim. Clearly, the intention is that most of the solution will take a direct route through the wash load. Nevertheless, Whirlpool objects to Defendants' introduction of a limitation -- "but not over or around them" -- because such a limitation is not justified by Claim 13 or the specifications. Claim 13 merely recites passing solution through the wash load. It does not state that all of the solution will pass through the wash load or that no solution will ever go over or around the wash load. The specifications also note that the solution will take a "relatively direct (radial) path" through the fabric. '666 Patent, col. 6 ll. 2-3 (emphasis added).

At oral argument Defendants introduced a proposed construction of "passing [detergent solution] through the wash load, not merely over or around." This construction captures the essence of the claim without prohibiting some solution from going around the wash load. Accordingly, the Court will adopt this construction.

GO BACK

4154

The final claims in need of construction in the '648 patent are Claims 36 and 37, as dependent upon 36. Claim 36 reads as follows: "A method of making a pre-slit injection site having a housing and a septum comprising the sequential steps of: 1) forming a fluid flow path through the housing; 2) inserting the septum into an end region of the housing; 3) applying radially directed resealing forces to the septum; and 4) forming a resealable opening at least partway through the septum either during or after the preceding step." The interpretation of the first three steps is at issue here.

There is very little guidance in the prosecution history or specification as to the proper construction of these phrases, except for step three, which will be discussed below. Therefore, the court had to construe the phrases in light of their ordinary, literal meaning and the context in which they are used in this claim.

First, Claim 36 is a method-of-manufacture claim, requiring that each step be done in order, or sequentially. What is being manufactured in this claim is the injection site. The first step requires the maker to form a fluid flow path through the housing. The parties disagree as to whether this means the flow path must go through the housing piece entirely or whether the path is only the area below where the septum will be placed during the next step. The court concludes, based upon the ordinary meaning of "through," that the fluid flow path must be formed from one end of the housing to the other.

"Through" is defined as: a penetration of or passage within, along or across an object, substance, or space usually from one side or surface to the opposite one; passage from one side to another of an object. This definition indicates that plaintiff meant to convey, in step one, that the fluid flow path was to run from one end of the housing to the other.

Further support for this conclusion can be found in the sequence of steps chosen by plaintiff in drafting the patent. This path is created before the septum is placed in the housing. It would not make sense to interpret the path as ending at an element of the invention that is not yet a part of the invention. In addition, for the path to end at a certain spot along the housing,
where the septum has not yet been put into place, the maker would have to erect a barrier at some point in the path. This would defeat the purpose for the invention: namely, this barrier would prevent the blunt cannula from entering the fluid flow path.

Support from the specification comes from plaintiff's repeated reference to a specific part of the housing when indicating where something is located in the housing. For example, column 2, lines 25-26, state: "The housing can also be formed with the first end including an annular channel," and column 7, lines 59-62, state: "Curved end regions of the members slidably engage the second end of the housing when the piercing member of the blunt cannula has been forced through the pre-formed opening…." A reference to which end of the housing has the fluid flow path is conspicuously absent from the first step of Claim 36. Instead, the claim states the path is formed through the housing.

Plaintiff points to other language in the specification, which it contends demonstrates that the flow path is only formed underneath the septum. Specifically, plaintiff references column 6, lines 52-53, which read: "The resealable septum closes the fluid flow path." Contrary to plaintiff's contention, the court concludes that this language further supports the court's construction of the claim. Closing a path implies that it was previously open. Therefore, the flow path was open until the second step, when the maker inserts the septum and closes it off.

Greenkeepers and Defendant ECCO contest whether the term "lateral stability and traction through the plane of a golf swing" is definite. The other Defendants did not propose a construction or address the definiteness of this claim term in their construction briefs, although they contend that once the word "to enhance" is added, the term is indefinite, a contention that the Court will address infra.

1. The Parties' Contentions

Greenkeepers contend that, under Federal Circuit law, the contested terms are entitled to a presumption of definiteness. (Pls.' Opening 19-21; Pls.' Resp. 22-23.) For "lateral stability and traction through the plane of a golf swing," Greenkeepers aver that the patent specification identifies as the preferred embodiment a set 37.5 degree of outward angulation, that provides a "defined reference baseline from which a person or ordinary skill in the art could determine how much outward angulation . . . is required to provide lateral stability and traction through the plane of a golf swing, without undue experimentation." (Pls.' Opening 20-21.) Greenkeepers continue that commonsense provides that "through the plane of a golf swing" refers to the time period during which a golfer swings. (Pls.' Resp. 25-26.)

ECCO urges the Court to find that "lateral stability and traction through the plane of a golf swing" is indefinite. For "lateral stability and traction," ECCO contends that these indicators are affected by multiple variables, including the orientation of the golf cleats, the action of the foot during the golf swing, and the weather and turf conditions. (ECCO Opening 33-35.)
ECCO continues that the '047 Patent's prosecution history concerns that there is no objective measure for lateral traction and stability, because Greenkeepers distinguished prior art McMullin cleats because there was "no basis" for finding that such cleats inherently enhanced lateral traction and stability, and "depending on the size of the angle, you might or might not achieve that function." (ECCO Resp. 26-28.) As for "through the plane of a golf swing," ECCO avers that this does not make any sense in the claim term, because the golf cleats can only provide traction and stability by interacting with the ground, but the plane of the golf swing does not go "anywhere near the shoes or cleats." (ECCO Opening 32-33 (emphasis omitted).) ECCO contends that Greenkeepers cannot rewrite their claims to replace "through the plane of a golf swing" with "during the golf swing." (ECCO Resp. 25-26.)

2. Analysis

Under 35 U.S.C. § 112, ¶ 2, the claims of a patent must "particularly point[ ] out and distinctly claim[ ] the subject matter which the applicant regards as his invention."

The primary purpose of the definiteness requirement is to ensure that the claims are written in such a way that they give notice to the public of the extent of the legal protection afforded by the patent, so that interested members of the public, e.g., competitors of the patent owner, can determine whether or not they infringe. That determination requires a construction of the claims according to the familiar canons of claim construction.

All Dental Prodx, LLC v. Advantage Dental Prods., 309 F.3d 774, 779-80 (Fed. Cir. 2002) (citations omitted). "A claim is considered indefinite if it does not reasonably apprise those skilled in the art of its scope." IPXL Holdings, L.L.C. v. Amazon.com, Inc., 430 F.3d 1377, 1383-84 (Fed. Cir. 2005). This construction must be understood "in light of the specification of which they are a part. Indeed, a patentee may be his or her own lexicographer by defining the claim terms." Oakley, Inc. v. Sunglass Hut Int'l, 316 F.3d 1331, 1340-41 (Fed. Cir. 2003). Also, a "patentee need not define his invention with mathematical precision in order to comply with the definiteness requirement." Id. at 1341. Because a claim is presumed to be valid, the accused infringer has "an evidentiary burden of clear and convincing evidence to show facts supporting a conclusion of invalidity," Cement Mfg. Corp. v. CTS Cement Mfg. Corp., 587 F.3d 1339, 1351 (Fed. Cir. 2009), and the claim "is indefinite only if [it] is insolubly ambiguous, and no narrowing construction can properly be adopted," Honeywell Int'l, Inc. v. Int'l Trade Comm'n, 341 F.3d 1332, 1338-39 (Fed. Cir. 2003) (quotations omitted).

The Court is not persuaded that "lateral stability and traction through the plane of a golf swing," is "insolubly ambiguous." Id. at 1339. Although "lateral stability and traction" appear to be affected by many different factors, such as weather and turf conditions, and the unique swing and foot action of the golfer, the parties have already agreed that "traction" means "the adhesive friction of a body on a surface" (Pls.' Opening, App'x I, at 1), and an ordinary person trained in the arts, employing commonsense, would understand that "lateral stability" refers to the ability to resist slipping to the side to permit the golfer to maintain balance and control while swinging. Moreover, ECCO's strained reading of "through the plane of a golf swing" as imposing a spatial rather than a temporal limitation, thereby rendering the term nonsensical (ECCO Opening 32-35), fails to show invalidity by clear and convincing evidence; rather, the term can be readily and reasonably understood as referring to lateral stability and traction as a golfer completes his or her golf swing. The Court, therefore, presumes that "lateral stability and traction through the plane of a golf swing" is definite, and adopts Greenkeepers' construction.

4156

5. through the tubular housing and over the pen to the outlet orifice

P&M construes "through the tubular housing and over the pen to the outlet orifice" as "along the housing and pen to the outlet orifice," meaning that "the air passes from the mouthpiece, over the pen's nib, via the housing." (Pls. Opening Mem. at 18.) Rose Art construes this term as "the passage of air from one end of the tubular housing or elongated hollow tubular casing, on or on top of the entire pen (not just the absorbent nib), and out the other end of the tubular housing or elongated hollow tubular casing," and contends that the term requires that "the air travels within the confines of the tubular housing and passes over the entire pen (not just the absorbent nib)." (Def. Pre-Markman Hr'g Brief at 25.)

Rose Art's suggested construction of the disputed term would exclude the fig. 8 preferred embodiment. In the fig. 8 embodiment: "air is blown through the mouth piece 27 and tube 26 into the barrel 20 from which it passes over the nib 24 to
remove ink particles therefrom which leave as fine spray within the air flow through the nozzle orifice 25." ('886 patent, col. 3, ll. 22-26.) Since the reservoir pen is not entirely encased within the housing in the fig. 8 embodiment, the air does not pass over the entire pen. Rose Art's suggested construction of the disputed term would limit the patent to the figs. 1 and 4 preferred embodiment. Consequently, the Court cannot adopt the construction urged by Rose Art because that construction would limit the meaning of claim 1 to one preferred embodiment. Rodime PLC, 174 F.3d at 1303. Accordingly, the term "through the tubular housing and over the pen to the outlet orifice" is construed as "along the housing and pen to the outlet orifice." Since the entirety of the intrinsic evidence with regard to this term is not ambiguous, the Court did not consider the extrinsic evidence submitted by the parties with respect to this term.

III. RELEVANT LANGUAGE OF THE PATENT-IN-SUIT

The parties agree that what remains at issue before the Court in this Markman process is the correct interpretation of the portion "throughhole passing through the dielectric layer" as used in the claims 1 and 15 of the '555 Patent. Specifically, the '555 Patent claims the following:

1. A deactivatable resonance label, comprising: a dielectric layer having first and second opposed faces;

   a first conducting layer on the first face of the dielectric layer, the first conducting layer being shaped to form an inductor and a first capacitor plate;

   a second conducting layer on the second face of the dielectric layer, the second conducting layer being shaped to form a second capacitor plate, the first and second conducting layers being at least partially superposed, said first and second conducting layers and said dielectric layer forming together and oscillating circuit; and

   shorting means for enabling creation of a short-circuit between the first and second conducting layers when it is desired to deactivate the oscillating circuit, the shorting means being comprised of at least one throughhole passing through the dielectric layer to provide a short circuit path between the first and second conducting layers.

15. A method for fabricating a deactivatable resonance label, said method comprising steps of:

   providing a planar dielectric layer having first and second faces . . . . and

   forming shorting means in the dielectric layer for enabling creation of a short-circuit between the first and second conducting layers when it is desired to activate the oscillating circuit, the shorting means being comprised of at least one throughhole passing through the dielectric layer to provide a short circuit path between the first and second conducting layers.

'555 Patent, col. 7, ln. 33-52; col. 8, ln. 33-34, 47-55 (emphasis added).

IV. CLAIM CONSTRUCTION

The scope of protection provided by a patent is determined by the language of the claims and the brief sentences or paragraphs which "particularly point[] out and distinctly claim[] the subject matter which the applicant regards as his invention." 35 U.S.C. § 112. The first step in determining the infringement of a patent is an interpretation of the scope and meaning of the patent claims alleged to be infringed, and construction of those patent claims is a matter of law to be decided by the Court. See Markman, 52 F.3d at 979. In order to aid the Court in this determination, the parties submitted written briefs and made presentations at a Markman hearing. The parties have presented competing descriptions of the proper construction of the patent claims.

A. Summary of Positions on Claim Interpretation

1. Checkpoint

Plaintiff Checkpoint argues that the proper interpretation of the claimed dispute of the '555 Patent is that the "throughhole"
is only properly interpreted as its name suggests. That is, the throughhole is a hole (air-filled space, free of dielectric layer material) through one of the energy conducting layers of the resonance labels, which makes the resonance label operate more efficiently and effectively.

Furthermore, Checkpoint argues that the throughhole is a structural implementation that uniquely improves and advances the design of the resonance label, and sets it apart from prior versions of the label.

It is Checkpoint's position that "the 'throughhole' provides a short circuit path between the conducting layers." Checkpoint disagrees with Defendants' definition, infra, of the throughhole as being limited by and distinguishable from Defendants' use even if there is a difference in or there is uniformity of the thickness of the conducting layers. Simply put, Checkpoint argues that the meaning of "throughhole" puts no limitation on where the hole can be put on a conventional label, and that the "throughhole" works regardless of what the thickness of the label is like where the hole is placed. To that end, Checkpoint argues that the patentee did not and would not have disavowed having the hole in an area of reduced thickness, as Defendants suggest.

As a matter of law, Checkpoint states that the Federal Circuit's recent ruling in Phillips v. AWH Corp. controls the proper construction of a patent's claims in support of Checkpoint's proposed meaning of "throughhole". 415 F.3d, 1303, 1312 (Fed. Cir. 2005). Specifically, Checkpoint argues that the court in Phillips has stated that an inventor's claims should be used to determine what he regards as his invention when there is an ambiguous claim term, but should not necessarily limit the scope of the patent's protection. Id. at 1312, 1323.

2. All-Tag

Defendant All-Tag relies on a different reading of the Phillips court's pronouncement that the specification "is always highly relevant to the claim construction analysis . . . [and] [u]sually, it is dispositive; it is the single best guide to the meaning of a disputed term." I d.

All-Tag argues that claim construction turns on the meaning of the word "throughhole" and the word "layer" as used intrinsically, in the context of the entire claim. All-Tag's position, based on its reading of Phillips is that because "throughhole" and "layer" are not ordinary terms of art, the specification and prosecution history, rather than the inventor's claims, should be used to construe the terms for purposes of determining the validity of the '555 Patent in the Defendant's favor. According to All-Tag, Checkpoint's construction of the "throughhole" as a "space" cannot survive the specification and prosecution history analysis set forth and required by Phillips.

Furthermore, All-Tag argues that its use -- selective reducing of the thickness of a layer in the resonance label -- is specifically critical of and inapposite to the asserted design of the '555 Patent. Thus, All-Tag's position is that its product and design do not infringe upon the '555 Patent.

3. Sensormatic

Defendant Sensormatic's argument parallels Defendant All-Tag's in that Sensormatic states that the term "throughhole" must be construed according to specification and prosecution history in accordance with legal principles of claim construction. Specifically, Sensormatic argues that the term "throughhole" did not appear in the original application for the '555 Patent. Rather, "throughhole" was added to the application for the express purpose of distinguishing the "hole through the layers design" (Checkpoint's alleged use) from the "reduced thickness in layers design" (All-Tag & Sensormatic's alleged use).

B. Interpretation of the Terms of the '555 Patent

There is no dispute that both Plaintiff's and Defendants' proposed labels are workable, functional structures. Therefore, the language of the claims and the brief sentences or paragraphs must "particularly point[] out and distinctly claim[] the subject matter which the applicant regards as his invention." 35 U.S.C. § 112. Furthermore, in order for the Court to accept Defendants' construction of "throughhole" such that the functional "hole through the layers design" is distinguishable from the functional "reduced thickness in layers design", the record must reflect the patentee's clear intent to disavow placement of the hole in some area of reduced, or otherwise non-uniform, thickness. See Katz, 63 F. Supp. 2d at 591 (citing York Prods., Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1572 (Fed. Cir. 1996)) ("[u]nless altering claim language to escape an examiner rejection, a patent applicant only limits claims during prosecution by clearly disavowing claim
coverage,' that is, by making a statement that concedes or disclaims coverage of the claims at issue based on a piece of prior art.

Checkpoint's proposed construction of "throughhole" is consistent with the context of the patent claims. Claims 1 and 15 describe a "throughhole passing through the dielectric layer to provide a short circuit path between the first and second conducting layers". (col. 7, ln. 49-52; col. 8, ln. 51-55.) Defendants' proffered construction describes "an opening extending through the entire, predetermined, uniform thickness of the dielectric layer". (Def. Sensormatic Electronics Corp.'s Initial Claim Construction Brief 24; All-Tag Defs.' Brief on Claim Construction at 24.) However, this construction imposes a limitation that is inconsistent with the language evidenced by the patent claims.

The prosecution history supports the inventor's use of the term "throughhole" inasmuch as the term "throughhole" was used in place of "hole or cut" without any additional qualification or disavowal of a specific thickness of the layer through which the hole or cut is made. Furthermore, the language in the '555 Patent specification that describes the absence of "[e]ffects such as fluctuations in thickness" (col. 2, ln. 45-47) is properly understood in the full context of the claim as the manner in which deactivation occurs, not a departure from the prior art regarding fluctuations in thickness of the dielectric layer. ('555 Patent, fig. 3; see col. 3, ln. 48-49 and col. 6, ln. 45 (illustrating an embodiment of the invention where the dielectric layer is reduced in thickness)). Rather, it is the continuous hole that is the deviation from prior art and therefore the inventor's invention. (col. 4, ln. 11-13.)

V. CONCLUSION

Having found no clear intent on the part of the patentee to require uniform thickness in the material penetrated, this Court concludes that the term "throughhole" and layer as used in the claim "throughhole passing through the dielectric layer" means "a space between the first and second conducting layers free of dielectric layer material". Furthermore, "throughhole" is not an ambiguous term. This term is construed in accordance with the claim and specification, and dictated by its ordinary and customary meaning. The Court agrees with Checkpoint's proposed construction because it is supported by the consistent use of the word "through" in the claim language ("one through hole passing through the dielectric layer"), in the context of the entirety of the invention, and construed in accordance with the specification. See Markman, 52 F.3d at 979 (stating that claims must be read in view of the specification of which they are a part.). Claim 1 only qualifies the term "throughhole" as "passing through the dielectric layer," and does not include language limiting a throughhole to an area of uniform thickness in the dielectric layer. Therefore, the construction of "throughhole passing through the dielectric layer" as "a space between the first and second conducting layers free of dielectric layer material" is proper as evidenced by the patent's claim, the specification, and the prosecution history. An appropriate Order follows.

AMENDED ORDER

AND NOW, this day of February, 2007, IT IS HEREBY ORDERED AND DECREED that the Court's January 24, 2007 Order (Doc. 213) is AMENDED as set forth herein and as set forth in the accompanying memorandum.

Upon consideration of the briefs and materials submitted by the parties, and after a Markman hearing on patent claim construction, it is hereby ORDERED that the disputed term "throughhole" in the claims of United States Patent No. 4,876,555 (the '555 patent) shall be construed to have the definition herein assigned to it. The Court concludes that "throughhole" means "a space between the first and second conducting layers free of dielectric layer material".

GO BACK

4158

H. "Through," "Throughout," and "Throughout the Entire":

"Throughout the substrate" (claims 1 and 2)

"Through the substrate" (claim 3)

"Throughout the entire substrate" (claim 7)

Ixys and APT disagree as to whether the terms "through," "throughout," and "throughout the entire," which are collectively employed five times in claims 1, 2, 3, and 7 of the '202 patent, necessitate that the transition metal that is to be deposited

- 4816 -

PUBPAT
"throughout" or "through" the substrate be diffused into the entire substrate, or merely into certain layers. The dispute over these terms stems in part from the slightly different contexts in which the words are used, and the parties make a number of different arguments specific to particular claims in particular contexts. In order to deal with these various arguments in as clear and through a manner as possible, the court will address each section of claim language (and the arguments accompanying it) separately.

1. "Throughout the Entire Substrate" (claim 7)

This claim term offers a useful starting point because the parties agree on its meaning. The court construes this claim language to mean: "Through every part of the substrate."

2. "Throughout the Substrate" (claim 1)

This phrase appears in two places within claim 1. In order to better elucidate the context in which the term is used, the entire section involving this term is reprinted here:

`diffusing the metal atoms throughout the substrate at a temperature within said range, including:

diffusing a first portion of the dose throughout the substrate; and

diffusing a second portion of the dose in a gradient band near a selected surface of the substrate.``

'202 patent, Claim 1 (emphasis added). The claim language itself, within the context of the terms surrounding it, forms the starting point of any construction analysis and is the most important factor that a court must consider, and thus the court will address the contextual understanding of this language first. Vitronics, 90 F.3d 1582. In this claim, the language at issue appears to be establishing a comparison between two steps, and two types, of diffusion: the metal atoms are diffused through every part of the substrate in two steps, the first being a broad diffusion of atoms through every part of the substrate, and the second a more limited diffusion in just a gradient bandwidth near the substrate surface. The implicit contrast is between the "first portion" of the dose which is diffused ubiquitously, and the "second portion," the deposition of which is limited to the area near the surface of the substrate.

APT, the owner of the '202 patent, protests that the specifications and the very nature of the invention militate strongly against reaching such a conclusion and teach away from finding a requirement that transition metal pervade the entire substrate. APT points to three sections of the specifications that it claims represent preferred embodiments that do not require metal through "every part" of the substrate and thereby support its position. As this court has noted previously, it is presumptively unreasonable and improper to construe the claims in such a way that a preferred embodiment is excluded. See id. at 1582.

However, the three parts of the specifications relied upon by APT do not significantly aid its position. APT first references Figure 17, a graph of transition metal concentration vs. depth within the semiconductor for different types of dose and diffusion mechanisms. '202 patent, Figure 17. APT notes that at a certain depth (the x-axis of the chart is unmarked, and so that depth is unknown), the line graph showing the concentration of atoms intersects the x-axis (presumably implying that the concentration is zero); APT therefore concludes that the transition metal "extends only partially into the semiconductor." APT's Opening Br., at 11. However, the y-axis of this graph also lacks a label, and so there is no indication that the x-axis actually represents the point at which transition metal concentration equals zero. Rather, it may be that the graph is in some sense "normalized" based on the diffusion of the "first dose" throughout the substrate; the background concentration of transition metal is dropped from the analysis, and the graph itself represents only the concentration due to the diffusion of the second portion above the already extant level.

APT also points to two sections within the same paragraph of the specifications. The first of these two sections is rather opaque, and as such sheds little light on the current issue. The specifications teach that "Low lifetime control doping in the bulk of the epitaxial layers combined with a higher concentration near the substrate surface adjacent the PN junction can provide the best effect." '202 patent, 24:8-12. This language does not employ the word "throughout," nor does it preclude diffusion throughout the entirety of the substrate, since the specification language does not indicate whether the substrate may be doped only in the epitaxial layers, or additionally elsewhere. The second of these sections essentially mirrors (in
First, the substrate is lightly dosed with, e.g., 10<11> Pt atoms/cm<2>, and diffusing the Pt atoms throughout the device at first elevated temperature, e.g., 850 [degrees] -865 [degrees] C. for one hour for a PIN. Second, an additional dose of Pt atoms is applied to a selected surface of the device and is diffused at a higher temperature, e.g., 950 [degrees] -1100 [degrees] C. for 5-20 seconds (rapid thermal anneal) such that the additional dose is retained in a gradient band near the selected surface.

APT's final argument with reference to the particular language in Claim 1 draws upon the fact that both parties have agreed that "throughout the entire substrate" in Claim 7 means that metal must be diffused in every part of the substrate. APT contends that adopting Ixys' position and construing "throughout" to mean "through every part of" would eviscerate any possible meaning that might be attached to the word "entire." See, e.g., Apple Computer, 234 F.3d at 25 (Fed. Cir. 2000). APT is certainly correct about this fact; however, such arguments from linguistic logic are not, by themselves, sufficient to overcome the plain language and context of the disputed claim terms themselves. Finally, Ixys notes that the plain meaning of the word "throughout" is "in, to, through, or during every part of; all through." American Heritage Dictionary of the English Language (4th ed. 2000). The dictionary definition of a word is hardly decisive in this context, but it does serve to buttress the impression that the claims and specifications have already made.

APT offers one additional argument related to the phrase of claim 2 that describes "diffusing the metal atoms throughout the substrate at a temperature within said range." '202 patent, claim 2. Claim 7 is a dependant claim based upon claim 2 which describes "The fabrication process of claim 2 wherein the transition metal is tailored to have a relatively shallow profile compared to a completed diffusion throughout the entire substrate." '202 patent, claim 7. APT protests that if the diffusion process described in claim 2 already involves spreading transition metal atoms throughout the entirety of the substrate, the process described in claim 7 (which is dependant upon claim 2) must contain all the limitations of the claim 2 process, and thus cannot simultaneously include metal diffused throughout the substrate and "have a relatively shallow profile compared to a completed diffusion throughout the entire substrate."

If a "shallow profile" literally meant that there could be no transition metal atoms deposited below a certain (shallow) depth, APT would seem correct in noting this inconsistency. However, the parties have already agreed that a "shallow profile compared to a completed diffusion throughout the entire substrate" must be understood to mean that "there is a higher concentration of transition metal atoms near the surface of the substrate, and a lower concentration of transition metal atoms in the substrate, than there would be with a completed diffusion throughout the entire substrate." See (G), supra. It is entirely possible to comply with both requirements simultaneously: a substrate would contain metal throughout every part, but a lower concentration would be present at greater depths (and a higher concentration present at shallower depths) than would exist after a "completed diffusion" (namely one in which no metal is purposefully retained near the surface in a gradient band). APT's contentions on these grounds thus lack merit.

APT's final argument seizes upon the language of dependant claim 3, which directs one skilled in the art to diffuse the transition metal "through the substrate" using a rapid thermal anneal process. APT notes correctly that the only discussion of the "thermal anneal" process within the specifications comes in reference to the deposition of the "second portion" of the transition metal dose. There, the specifications state that the second portion of the dose is diffused according to "(rapid thermal anneal) such that the additional dose is retained in a gradient band near the selected surface." '202 patent, 24:19-21. This conclusive linkage between a "thermal anneal" process and the diffusion of atoms only within a thin band near the surface of the substrate provides a strong indication that the word "through" in this claim cannot mean "throughout the entirety" of the substrate.
APT also argues that it is physically impossible to diffuse transition metal throughout an entire substrate using a rapid thermal anneal process. See APT's Opening Br., at 12. Since claims are to be construed as they would be understood by an individual skilled in the art, there is certainly good reason not to read a claim to create a physical impossibility. However, APT cites to know scientific authority, intrinsic or extrinsic, for this proposition, and thus the court will not consider it further.

APT's reasonably strong showing that "through" should be construed in such a way that it does not require that metal be diffused throughout the entirety of the substrate creates additional problems in this analysis. Claim 3 is a dependent claim of claim 2 that describes a specific process for diffusing "the selected transition metal," and claim 2 requires "diffusing the metal atoms throughout the substrate." If claim 2 is construed such that metal must be diffused into every part of the substrate, Claim 3 must contain the same limitation. Reciprocally, if claim 3 does not require that transition metal be diffused throughout the entire substrate, claim 2 must not either. And if the word "throughout" in claim 2 does not require diffusion throughout the entire substrate, the desire for harmony among the claims would militate against construing the term "throughout" in claim 1 to require diffusion throughout the substrate and thereby attaching to it a meaning different than the same term in claim 2.

The ties among these claims leaves this court with very little choice but to construe them all in congruent fashion, and in the face of conflicting and essentially irreconcilable implications in the claims and specifications (as well as the dictionary). Although both parties have put forth reasonable cases, it seems to the court that the preponderance of the evidence weighs in favor of attaching to "throughout" and "through" the meanings that the plain language and the structure of the claims themselves would most appear most clearly to dictate. The court construes all of the claim terms at issue here to mean: "Throughout every part of the substrate."

2. The term "thumbwheel" in claim 34 is construed as "an input device consisting of a dial or wheel, inset into a surface so that only a portion of its rim protrudes, and that can be rotated either clockwise or counterclockwise around its axis;"

Although the district court concluded that the specification supports its construction of "tie yarns," we disagree. The portion of the specification that refers to tie yarns as "not visible from the face side of the fabric," '401 patent, col. 3, ll. 50-51, is found in the description of the "3-end knit." The specification does not indicate that the 3-end knit is implicit in claim 17, or that the characteristic of the tie yarns described in that portion of the specification, i.e., not being visible from the face side of the fabric, is necessarily found in structures other than the 3-end knit. Thus, according to its terms, claim 17 would read on a fabric that uses only two yarns--a nap yarn forming the back layer of the knit, and a tie yarn performing the functions of tying the back layer of the knit to the face layer and making up the face layer itself.

Moreover, claim 18, which depends from claim 17, adds the limitation that "said knitted face layer further includes a plurality of flame resistant face yarns which follow substantially identical parallel paths along said knitted face layer as said flame resistant tie yarns, said face yarns forming a face surface on said knitted face layer which is adapted to face the garment wearer." The addition in claim 18 of the limitation requiring a face surface formed of face yarns (that is, stitch yarns) suggests that claim 17 does not require that the face layer include face yarns, much less that it consist exclusively of face yarns. See Phillips, 415 F.3d at 1314-15 ("[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim."). Although it is possible to distinguish claim 18 from claim 17 by reference to the additional limitation in claim 18 that the face yarns "follow substantially identical parallel paths along said knitted face layer" as the tie yarns, the most conspicuous difference between claims 17 and 18 is the addition of the "face yarn" limitation. Therefore, absent a clearer indication that the "face yarn"
limitation was included in claim 17 by implication, we conclude that the difference between claims 17 and 18 supports Southern Mills' argument that claim 17 does not require the presence of a separate "face yarn" or stitch yarn.

Based on the language of claim 17 and its context, we therefore conclude that the district court's ruling that tie yarns are "not visible from the face side of the knit" is erroneous as applied to claim 17. While the patent makes clear that tie yarns are not visible from the face side of the fabric in the "3-end knit" that is recited in most of the claims, that is not true of claim 17, which does not require the use of the "3-end knit," either expressly or by clear implication. Because we disagree with the district court's construction of the term "tie yarns" as applied to claim 17, and because the parties agreed to a consent judgment based on the court's claim construction order, we reverse the judgment with respect to claim 17 and its asserted dependent claims. The judgment is otherwise affirmed.

A. "Tight Joint"

The court determined that "water tight" and "water tight joint" are terms defined within the patents: "A joint is water tight when standing water will not penetrate the joint for several hours." (970 patent col. 3 ll. 43-44." (See Order 11, May 12, 2006.) Alloc urges the court to give the term "tight joint" the same meaning that it gave the terms "water tight" and "water tight joint": "a joint that will not allow standing water to penetrate for several hours." Pergo argues that "tight joint" is broader than "water tight" and refers to a joint that will not allow water or dirt from penetrating the joint. See '970 patent col. 3 ll. 29-31 ("Of course, without any substantial gaps between the panels, water and dirt are prevented from entering the assembled panels, flooring or wall covering.").

The court determines that "tight joint" is broader than "water tight joint" and means that neither dirt nor water may penetrate the joint. With respect to water, "tight joint" means that standing water will not penetrate the joint for several hours. See '970 patent col. 3 ll. 40-43 ("... to bring said panels into forming a tight joint such that the joint is said to be waterproof or water tight. A joint is water tight when standing water will not penetrate the joint for several hours.").

(3) Center Tilt Mount

Claims 1, 44, 45, 49-52 of the '988 Patent also uses the phrase "center tilt mount." Innovative asserts that center tilt mount should be construed according to its ordinary meaning as a "a center mount configured to tilt." Defendants again look to the patent specification to advance a narrower claim construction, arguing that center tilt mount means "a cast mount having a generally square shaped base with stops on the inner surface of the base, flanges having shaft holes for accepting a shaft, and a rivet hole in the center of the base." Defs' Markman Br. p. 25, (citing '988 Patent, Ex. E. col. 4 ll. 52-67). For the reasons stated above, the court will adopt Innovative's construction and find that "center tilt mount" means "a center mount configured to tilt."
tilting. (D.I. 53 at 12.) Accordingly, Defendants ask that "tilt valve" be construed to mean "a conventional off-the-shelf valve as generally known and widely used in dispensing apparatuses in which the valve is designed to be opened by tilting a hollow stem of the valve which is resiliently held on a container mounting cup by a rubber grommet." (Id.)

The parties thus agree at least that a tilt valve can be opened by tilting. Whether such a valve can also be opened by axial displacement goes to the parties' dispute over whether Defendants' accused products infringe the '064 patent, not to whether the '010 PCT publication discloses a tilt valve.

The '010 PCT publication mentions a "tilt valve" in only one passage, which states, in relevant part:

It should be noted that the boss portion 224 is only one of many possible fittings for the top piece 226. The top piece 226 is a standard open top cone and may, in other embodiments, have other valve assemblies fitted therein. For example, a standard aerosol valve such as a spray valve or tilt valve (for dispensing cream, etc) may be fitted. It should also be noted that the upper profile of the piston assembly may require modification to accommodate components of such valves which protrude into the body of the can. This may be achieved using the hollow stem of the secondary (uppermost) piston to make room for the valve components when the piston assembly is in its uppermost position.

(D.I. 72, Ex. A at A-23.)

Rocep asserts, see infra at 11-13, that the use of the term "tilt valve" in the '010 PCT publication is to help define the type of "top cone" to be used with the valve disclosed in that publication. 2 (D.I. 70 at 9.) That argument does not suggest that "tilt valve," as the term is used in the '010 PCT publication, means something different than it does in the '064 patent. However, even if one were to interpret Rocep's argument to mean that "tilt valve," as used in the '064 patent, somehow means something different than the same words in the '010 PCT publication, the dispositive rejoinder is that no one has directed my attention to any evidence in the record indicating any difference. Nothing in the foregoing passage from the '010 PCT publication suggests a meaning for "tilt valve" that is other than the meaning conveyed in the '064 patent.

2 According to Rocep, "the reference to the tilt valve was for defining the type of cone (container) that the inventor considered to be useful with his dispenser. That is, he was defining the type of cone that could be used as the kind that is sometimes used with spray or tilt valves." (D.I. 70 at 9.)

I will therefore construe the term "tilt valve," for purposes of addressing the Defendants' invalidity motion, as meaning the same thing in the '064 patent and in the '010 PCT publication, and covering "a valve that can operate at least by tilting." 3

3 Were I addressing the summary judgment motions on infringement, I would feel the necessity to construe this term in a way that would address and resolve the "axial displacement" issue, which the foregoing construction does not attempt.

4164

A. Claim Construction

"Claim language generally carries the ordinary meaning of the words in their normal usage in the field of invention "at the time of invention. Invitrogen Corp. v. Biocrest Mfg., L.P., 327 F.3d 1364, 1367 (Fed. Cir. 2003). The specification generally provides the context for claim interpretation. Phillips v. AWH Corp., 415 F.3d 1303, 1315 (Fed. Cir. 2005). "It is important to keep in mind that the purposes of the specification are to teach and enable those of skill in the art to make and use the invention and to provide a best mode for doing so." Id. at 1323. Courts, however, must be careful to avoid reading
limitations from the specification into the claims. Comark Commc'ns, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir.1998). The line between construing claim terms and importing limitations from the preferred embodiments into the claims "can be discerned with reasonable certainty and predictability if the court's focus remains on understanding how a person of ordinary skill in the art would understand the claim terms." Phillips, 415 F.3d at 1323.

The district court determined that the claim term "tip" requires "a separate elongated attachment to be fitted to the connecting body." The claims recite "a solid metal tip." Claims 1 and 2, for example, require "bending a solid metal tip." '714 patent, col. 17, ll. 49 to col. 18, ll. 59, 61. Claims 1 and 2 also require drilling or forming a passageway in the tip. Id. Claim 2, further recites "[a] method of making a transducer activated tool tip." Id. Additionally, claim 2 requires the tip to have inlet and outlet ends, further suggesting an independent attachment.

The specification also consistently describes the invention in a manner that suggests the tip is a separate attachment. For instance, the "Abstract" describes the "invention" as "provid[ing] a method of making a transducer activated tool tip." '714, Abstract (emphasis added). The tip consists of: (1) a substantially linear tip body,(2) a fluid inlet end, and (3) a subgingival fluid outlet end. Id. Under the heading "Method of Making a Tool Tip and Tool Tip," the specification states: "[t]he tip is typically attached to an electro-mechanical part or section that can be induced to vibrate." Id. at col. 1, ll. 50-52 (emphasis added). Under this section, the specification further states "[g]enerally, the tip must be small in cross-section, ideally having a pointed tip . . . . More preferably the tapered cross-section extends about 10 mm from the distal tip end." Id. at col.2, ll.3-9 (emphasis added). Thus, the specification distinguishes "the tip" from the "pointed tip" and the "distal tip end," suggesting "the tip" is a discrete component and the "pointed tip"/"distal tip end" is a region of the tip.

Under the heading "Objects of the Invention," the patent describes"the object of the invention:" "to provide an insert" for an ultrasonic tool. The ultrasonic tool, in turn, is "a handpiece . . . a connecting body . . . and a tip, axiallyattached to the connecting body." Id. at col.3, ll.41-49 (emphasis added). Under the heading "Summary of the Invention," the specification again describes "the object of the invention:" "to provide an insert" for an ultrasonic tool. The tool then receives the same three-part description. Id. atcol.5, ll.65-68 to col.6, ll.1-6 (emphasis added). Thus, the term "tip" refers to an attachment.

Similarly, the preferred embodiment in Figure 3 below receives the following description:

The tip 20, the operative portion of the ultrasonically activated tool, comprises a smaller diameter distal tip portion 43S for contacting tooth surfaces, larger diameter portion 43L and a shank portion 44 that is secured to the connecting body 15. Smaller diameter portion 43S intersects larger diameter portion 43L at a tip surface angle transitionline L. The connecting body includes a counter bore for receiving the tip shank 44 which may be secured by brazing, mating threads or the like. A fluid passageway 45, described in detail below, formed interior to the tip element or body, exits through an internal or side wall in the tip to provide a fluid discharge orifice 46.

[SEE [title of photograph] IN ORIGINAL]

Id. at col.9, ll.20-23. This embodiment clearly illustrates the tip 20, as a separate attachment having a distal tip portion 43S and a tip shank portion 44. Indeed, the specification describes every preferred embodiment in a similar manner. Accordingly, both the claim language and the specification amply support the trial court's interpretation.

Claim Construction

Prior to trial, this Court held a hearing at the request of the parties for the sole purpose of construing the word "tip" as it appears in claims 1, 8 and 15 of the '064 Patent and claims 1 and 8 of the '125 Patent.

In an infringement action, the court first must determine the scope and meaning of the patent claims. See Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1454 (Fed. Cir. 1998). Claim construction presents a question of law to be decided by the Court. Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995), aff'd, 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996).
The Court of Appeals for the Federal Circuit had occasion to restate and clarify the standards for claim construction in Phillips v. AWH Corp., 415 F.3d 1303 (Fed. Cir. 2005) (en banc). Phillips emphasizes that "[i]t is a 'bedrock principle' of patent law that 'the claims of a patent define the invention to which the patentee is entitled the right to exclude.'" Id. at 1312 (citations omitted). The "words of a claim 'are generally given their ordinary and customary meaning,'" which "is the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention, i.e., as of the effective filing date of the patent application." Id. at 1312-13 (citations omitted). "[T]he person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." Id. at 1313. The specification may be the "single best guide to the meaning of a disputed term." Id. at 1315 (citation omitted). If it is in evidence, the prosecution history may also have important bearing on the meaning of a claim term, but it may lack the clarity of the specification and, hence, may be less helpful. Id. at 1317.

A court may resort to extrinsic evidence, though it is of less significance and less value to the claim construction process. Id. at 1317. Extrinsic evidence "consists of all evidence external to the patent and prosecution history, including expert and inventor testimony, dictionaries, and learned treatises." Id. (citations omitted).

After hearing the parties and reviewing their evidence, I construed the term "tip" as used in the patent claims to mean "that which serves as the end, cap or point of an object." (See 4/29/2005 Claim Construction Hrg., Tr. 52)

Claims 9 and 30

The pertinent language in claims 9 and 30 describe the detachable

"tip [as] comprising . . . a suction tube for aspirating irrigation fluid from the irrigation site, the suction tube having a fluid path that channels aspirated irrigation fluid externally of the handpiece and directly to a suction source, the suction tube and irrigation tube being detachable together from the handpiece whereby the tip can be discarded, enabling the handpiece to be reused . . . ." 1

452 Patent, Col. 8: 11, 18-24; Reexamination Cert., Col. 1: 55, 62-66; Col. 2: 1-2, 50-51, 58-64 (emphasis added). The specific language that Defendant identifies as the subject of this dispute is a "tip comprising" a "suction tube having a fluid path that channels aspirated irrigation fluid externally of the handpiece and directly to a suction source." Memorandum in Support of Defendant Stryker Corp.'s Renewed Motion for Summary Judgment at 6 (emphasis added). The parties concentrate on the meaning of the phrase "externally of the handpiece."

The Court first looks to the specific words in the claims and the context of the surrounding words. See generally Phillips, 415 F.3d at 1314. Both claims require that the detachable tip be comprised of a suction tube which has a fluid aspiration path that travels externally of the handpiece. The most telling language in the patent is the consistent and unequivocal claims' language that describes the tip.

The Court finds that the description of the tip in the patent's other claims gives considerable guidance in interpreting claims 9 and 30. See Phillips, 415 F.3d at 1314 ("The usage of a term in one claim can often illuminate the meaning of the same term in other claims."); see also Fromson v. Advance Offset Plate, Inc., 720 F.2d 1565, 1570 (Fed. Cir. 1983)("Significant evidence of the scope of a particular claim can be found on review of other claims."). Both claims 1 and 4 describe the tip as comprising "a suction tube for aspirating irrigation fluid from the irrigation site, the suction tube having a fluid bypass path within the detachable tip which channels aspirated irrigation fluid directly to a suction source so that aspirated fluid within
the suction tube does not enter" the handpiece. 452 Patent, Col. 7: 11-17, 31-32, 38-43 (emphasis added). The language in claims 1 and 4 require that the tip include both a suction tube and a fluid bypass path.

Claim 11 provides that the tip have a "suction tube for aspirating fluid from the site and a bypass fluid path in fluid communication with the tip suction tube . . . ." 452 Patent, Col. 8: 58-61. Claim 11 states that the tip have a suction tube and a bypass fluid path. Claim 7 provides for a "tip comprising . . . a suction tube for aspirating fluid from the irrigation site; and . . . the suction tube being in communication with a bypass fluid path which bypasses the interior of the handpiece to prevent the aspirated fluid within the suction tube from entering the interior of the handpiece." 452 Patent, Col. 7: 56, 58-59, 62-65; Reexamination Certificate, Col. 1: 34, 36-37, 40-43 (emphasis added). Claim 6 describes the tip "as defined by claim 4 wherein the fluid bypass path terminates at an open end suitable for connection to a suction source." 452 Patent, Col. 7: 49-51. Claim 15 provides that the tip have a "fluid bypass path associated with" it. 452 Patent, Col. 9:13. A consistent theme is emphasized throughout the claims -- that the tip include a suction tube and a bypass fluid path.

The Court concentrates on the description of the tip throughout the claims. "Claim terms are normally used consistently throughout the patent . . . ." Phillips, 415 F.3d at 1314. The claims' language consistently and clearly claims that the tip include a fluid bypass path within the tip. "In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words." Id. Reading the terms describing the tip in the claims in accord with their commonly understood meaning and in a consistent manner (as evidenced by their similar application throughout the claims) the Court concludes that a person of ordinary skill in the art would interpret the language of claims 9 and 30 as requiring that the device include a bypass path within the tip. The claims' language is clear in that the only manner in which the aspirated fluid flows externally of the handpiece is as a direct result of the bypass path contained within the tip. This interpretation is consistent with the clear purpose of the invention in avoiding contamination of the handpiece.

This interpretation is also consistent with the abstract. The abstract states that

"suction is provided through a suction tube which has a bypass conduit in the tip. The bypass conduit is directly connectable to a suction source so that aspirated debris passes through the tip to the suction source. The suction tube thus prevents aspirated debris from entering the conventional suction tube in the handpiece and contaminating the handpiece."

452 Patent, Abstract (emphasis added). Courts "frequently look[] to the abstract to determine the scope of the invention. . . ." Hill-Rom Co., Inc. v. Kinetic Concepts, Inc., 209 F.3d 1337, 1341 n.* (Fed. Cir. 2000). The Court finds that the specific and unambiguous language of the abstract provides that the tip contain a bypass path -- noted as a "bypass conduit."

The summary of the invention also supports the premise that the tip contain a bypass path. "It is among the objects of the invention to provide combination suction and irrigation tip that is detachably connectible to a handpiece and in which biological debris aspirated through the suction lumen bypasses the handpiece." 452 Patent, Col. 2: 53-56 (emphasis added). The language describing the tip is consistent with the claim's requirement that the tip contain a fluid bypass path that allows the aspirated fluid to bypass the handpiece and proceed directly to a suction source.

The illustrative embodiments of the 452 patent also emphasize the premise that the tip include a fluid bypass conduit.

GET DRAWING SHEET 2 OF 7

GET DRAWING SHEET 2 OF 7
GET DRAWING SHEET 3 OF 7

The tip 16 includes an inner (suction) tube 46 coaxially aligned within an outer (irrigation) tube 48, a flexible, funnel-shaped splash shield 54, and a connector 56. The suction tube 46 provides a direct pathway 50 for suction from the tip distal end 32 to a suction source. . . . Aspirated debris therefore never enters the handpiece 10.

452 Patent, Col. 3: 67; Col. 4: 1-7 (emphasis added).

The suction tube 46 is supported within the irrigation tube 48 at one end by an outlet nozzle 58, and at the other end by an elbow shaped conduit 60. . . . The suction tube 46 is sealed to both the outlet nozzle 58 and elbow-shaped conduit 60 to form a continuous suction lumen 64 from the tip distal end 32 to the tapered lower end 62 of the elbow 60 to which the suction tubing 20 from a suction source may be connected.

Although the elbow shaped conduit 60 is shown as extending from the proximal end of the suction tube 46, it may depend from any part of the suction tube 46. In an alternative embodiment, for example, the suction tube 46 is about half the size as it is in the preferred embodiment and the elbow shaped conduit 60 may connect to the suction tube 46 within the irrigation tube 48.

452 Patent, Col. 4: 25-31 (emphasis added). "When in use, the tip 16 is connected to the handpiece 10 and the flexible suction tubing 20 is connected to the tapered lower end 62 of the elbow shaped conduit 60." 452 Patent, Col. 6: 45-47 (emphasis added).

This language is consistent with the claims' language that the tip contain a bypass path. The tip contains an alternative avenue, represented in one of the embodiments by an elbow shaped conduit, in which the aspirated debris travels. The Court is mindful that this is not the only embodiment of the bypass conduit. Most telling is the specification's language that "although the elbow shaped conduit 60 is shown as extending from the proximal end of the suction tube 46, it may depend from any part of the suction tube 46." 452 Patent, Col. 4: 25-27 (emphasis added). This language is clear and consistent with the claims' language -- that although the bypass conduit may extend from any portion of the suction tube, it extends from the suction tube in the tip. The Court finds that the language of the illustrative embodiment does not limit the placement of the bypass conduit to where it originates from the tip (as noted by the permissive language "it may depend from any part of the suction tube") but it does limit the conduit to placement somewhere about the tip.

The prosecution history also supports the interpretation that the tip contain a bypass conduit. A preliminary amendment provided that:

The invention provides an arrangement by which the flow path of aspirated material is diverted away from and bypasses the handpiece. To that end, the detachable tip 16 has a suction tube 46 with, a conduit 60 that defines a fluid bypass path that prevents aspirated material from being channeled into contact with the handpiece . . . .

Memorandum in Support of Defendant Stryker Corp.'s Renewed Motion for Summary Judgment Ex. C. at 5 (emphasis added). Most notable in this passage is the clear and concise statement that the tip "has a suction tube . . . with a conduit . . . that defines a fluid bypass path . . . ." This language is consistent with the claims' language that the detachable tip include a suction tube with a bypass path.

A person of ordinary skill in the art is deemed to read the claim terms not only in the "context of the particular claim in which the disputed term appears, but in the context of the entire patent . . . ." Phillips, 415 F.3d 1313. The Court finds that when the patent is read as a whole -- it is clear that this is one of the instances where the meaning of the claim terms is readily apparent to "lay judges" as a result of the clear and consistent application of similar language describing the tip throughout the patent. See generally id. at 1314. The manner in which the tip directs the aspirated fluid "externally of the handpiece" is as a direct result of the bypass path contained in the tip. The Court concludes that a person of ordinary skill in the art would understand that the language of claims 9 and 30 requiring a "tip comprising" a "suction tube having a fluid path that channels aspirated irrigation fluid externally of the handpiece and directly to a suction source" requires that the tip include a bypass path.
The parties dispute the construction of "tip of the waveguide." Claim 1 recites "a waveguide having a tip for communicating electromagnetic radiation in a propagation direction to the tip of the waveguide." Claim 25 recites "a waveguide having a tip . . . the waveguide for communicating electromagnetic radiation in a first propagation direction to the tip of the waveguide." AMS proposes as a construction "the distal end portion of the waveguide, including any separate component(s) coupled thereto in a manner that prevents internal reflection at any interface between the components (for example by fusing or a transparent, index-matched adhesive)." LP proposes "a prism or the far end of the optical fiber having a core cladding over a fiber core."

The Court first considers LP's argument that "waveguide" is limited to an "optical fiber." AMS did not propose a construction for "waveguide," but argues that "waveguide" cannot be construed as only an "optical fiber" because claim 2, which depends from claim 1, recites "wherein the tip of the waveguide comprises a fiber optic segment." Similarly, claim 16, which indirectly depends from independent claim 7, recites "wherein the waveguide comprises an optical fiber." Under the doctrine of claim differentiation, these recitations create a presumption that the waveguide should not be limited to an optical fiber. See Nazomi Commc'ns, Inc. v. Arm Holdings, PLC, 403 F.3d 1364, 1370 (Fed. Cir. 2005).

LP contends that the waveguide is limited to an optical fiber because the title of the '699 Patent recites an optical fiber, the only waveguide taught in the '699 Patent is an optical fiber, and the '699 Patent uses the terms "waveguide" and "optical fiber" interchangeably. The title of a patent is nearly irrelevant to claim construction. See Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1312 (Fed. Cir. 1999). While the detailed description of the preferred embodiments does at times use the phrase "optical fiber or waveguide," the context of such usage suggests that an optical fiber is one example of a waveguide, not that a waveguide is always an optical fiber. E.g., '699 Patent col.8 ll.52-55 ("The fiber tip 51 can be formed into the distal end of an optical fiber 23 as a unitary component or coupled to the distal end of another optical fiber serving as a waveguide."), col.10 ll.6-9 ("The fiber 80 can be formed into the waveguide or attached to the distal end of an optical fiber or waveguide."). Moreover, the Summary of the Invention states: "The present invention comprises a waveguide, such as an optical fiber." This indicates that "waveguide" is a broader term than "optical fiber." See Catalina Mktg. Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 811 (Fed. Cir. 2002) ("Such as' introduces an example of a broader genus rather than limiting the genus to the exemplary species."). Finally, the dictionary definition of "waveguide" indicates that the ordinary meaning of a waveguide is not limited to an optical fiber. See Webster's Ninth New Collegiate Dictionary 1334 (1991) (defining "waveguide" as "a device (as a duct, coaxial cable, or glass fiber) designed to confine and direct the propagation of electromagnetic waves including light waves"). Based on the claims, specification, and dictionary definition, the term "waveguide" is not limited to "optical fiber."

The Court turns to the construction of "tip of the waveguide." The parties agree, and the specification and claim language indicate that the "tip" is located at the "distal" end of the waveguide, which is the end farthest from the energy source. The parties disagree, however, as to whether (1) the "tip of the waveguide" can constitute a separate component and (2) the "tube" shown in Figure 12 and the "cap" shown in Figure 2 can constitute a "tip of the waveguide."

As to whether the "tip of the waveguide" can be a component separate from the waveguide, nothing in the claim language indicates whether the tip can or cannot be a separate component. The Summary of the Invention, however, states: "According to another aspect of the invention, the tip is a separate component that is coupled to the distal end of the waveguide." The specification states: "While a fiber optic tip constructed in accordance with the present invention can be formed into the distal end of a waveguide, the tip of the present invention can be a separate component that is coupled to the distal end of a waveguide using transparent adhesive index matched to the waveguide." '699 Patent col.12 ll.51-59. Figure 11 illustrates such a separate tip that is coupled to an optical fiber by fusing or an index-matched transparent adhesive. See '699 Patent col.12 ll.60-68. The specification also states that the tip can be coupled to the distal end of the waveguide using an index-matched transparent adhesive "or otherwise." '699 Patent col.8 ll.52-58. The Court concludes that the "tip of the waveguide" can constitute a separate component. LP contends that the separate component is limited to the "prism" embodiment shown in Figure 11. The Court finds no basis in the specification or prosecution history for this proposed limitation. See Phillips, 415 F.3d at 1323.
The Court turns to whether the "tip of the waveguide" includes the "tube" shown in Figure 12 or the "cap" shown in Figure 2, which is an issue distinct from whether the tip of the waveguide can constitute a separate component. AMS contends that the cap and tube shown in Figures 2 and 12 must be included in the construction of "tip of the waveguide" because Figure 12 shows a "transmitting surface" on the surface of the tube. In other words, AMS reasons that because the specification identifies a transmitting surface on a tip in some embodiments and on a tube in other embodiments, the construction of "tip of the waveguide" must include a tube. LP responds that the claim language and specification require the exclusion of the cap and tube from the construction of "tip of the waveguide."

Claims 18 and 20, which depend from claim 7, are instructive. Claim 7 recites a waveguide having a reflecting surface and transmitting surface, both located on a tip of the waveguide. Claim 18 recites the apparatus of claim 7 further comprising "a tube with a hollow inside having a first end secured to the tip and enclosing the reflecting surface and transmitting surface." (Emphasis added.) Claim 20 recites "a transparent cap, secured to the tip and enclosing the reflecting surface and the transmitting surface." (Emphasis added.) This claim language indicates that the "tube" and "cap" are separate elements from the "tip of the waveguide." AMS contends that claim 19, which recites the apparatus of claim 7 further comprising "a transparent cap secured to the waveguide and enclosing the reflecting surface on the tip," supports a construction of "tip of the waveguide" that includes a tube or cap. The Court does not agree. A transparent cap that "enclos[es] the reflecting surface on the tip" plainly is a separate component from the tip.

This construction of the claim language is supported by the specification. The specification states that Figure 12 illustrates an embodiment of the invention "wherein a tube is coupled to the tip of the waveguide." '699 Patent col.3 ll.45-57. When describing Figure 12, the specification states that "a first end 103 of a transparent tube 100 having a hollow inside 109 is secured to a distal end 101 of an optical fiber or waveguide 102 having a bevelled end 106." '699 Patent col.13 ll.16-20. The specification states: "FIG. 2 illustrates an alternative embodiment wherein a cap 30 is secured around the distal end or tip 23 of the fiber 23. . . . The transparent cap 30 encloses the transmitting surface 25 and the bevelled end or surface 24 of the fiber 23." '699 Patent col.5 ll.42-44. The specification's description of the experiments indicates that the cap is a separate element from the distal end of the optical fiber having the reflecting surface. See '699 Patent col.11 ll.58-67, col.12 ll.21-24, col.12 ll.39. These descriptions of the cap and tube being coupled to and surrounding the distal end or tip of the waveguide indicate that the tube and cap are distinct elements from the tip.

To the extent that excluding a cap and tube from the construction of "tip of the waveguide" would exclude a preferred embodiment from the scope of claims 1 and 25, the Court is mindful that Federal Circuit case law "generally counsels against interpreting a claim term in a way that excludes the preferred embodiment from the scope of the invention." Helmsderfer v. Bobrick Washroom Equip., Inc., 527 F.3d 1379, 1383 (Fed. Cir. 2008); see Globetrotter Software, Inc. v. Elan Computer Group, Inc., 362 F.3d 1367, 1381 (Fed. Cir. 2004) (“A claim interpretation that excludes a preferred embodiment from the scope of the claim 'is rarely, if ever, correct.'”). However, claim constructions that exclude preferred embodiments, or even the sole disclosed embodiment, are correct when required by the unambiguous claim language. See, e.g., TIP Sys., LLC v. Phillips & Brooks/Gladwin, Inc., 529 F.3d 1364, 1372-73 (Fed. Cir. 2008) (“Therefore, the mere fact that there is an alternative embodiment disclosed in the '828 patent that is not encompassed by district court's claim construction does not outweigh the language of the claim, especially when the court's construction is supported by the intrinsic evidence.”); Lucent Techs., Inc. v. Gateway, Inc., 525 F.3d 1200, 1215-16 (Fed. Cir. 2008) (adopting construction that excluded only disclosed embodiment because "when the claims are susceptible to only one reasonable construction, we will construe the claims as the patentee drafted them"); Chef Am., Inc. v. Lamb-Weston, Inc., 358 F.3d 1371, 1372-74 (Fed. Cir. 2004) (construing "heating the resulting batter-coated dough to a temperature in the range of about 400[degrees] F. to 850[degrees] F." to exclude disclosed embodiments where the air, not the dough, was heated to the claimed temperature range because claims must be construed as drafted); Elekta Instrument S.A. v. O.U.R. Scientific Int'l, Inc., 214 F.3d 1302, 1308-09 (Fed. Cir. 2000) (construing claims to exclude only disclosed embodiment based on unambiguous claim language).

Moreover, the Federal Circuit has construed claim terms in a manner that does not cover the disclosed embodiments when such a construction did not mean the embodiments were excluded from the scope of the invention, but only that they were excluded from the scope of the construed claims. See Helmsderfer, 527 F.3d at 1383-84. "It is often the case that different claims are directed to and cover different disclosed embodiments." Id. at 1383; see Intamin Ltd. v. Magnetar Techs., Corp., 483 F.3d 1328, 1336-37 (Fed. Cir. 2007) ("Under the proper claim construction . . . the claim may well not cover this embodiment. Nonetheless, this court has acknowledged that a claim need not cover all embodiments."). Given the unambiguous language in the claims and specification, and the recitation of the tube and cap in claims 18-20, this is a case
where different claims may cover different disclosed embodiments. The Court construes "tip of the waveguide" as "the distal end portion of the waveguide, including a separate component coupled thereto in a manner that prevents internal reflection at any interface between the components (for example, by fusing or a transparent, index-matched adhesive), but not including a cap or tube enclosing a transmitting surface on the distal end portion of the waveguide or a reflecting surface on the distal end portion of the waveguide."

GO BACK

4168

The independent claims of the '347 Patent recite claims for a titanium centrifugal compressor wheel. Specifically, the '347 Patent provides as follows:

1. A titanium centrifugal compressor wheel formed by an investment casting process, and including:

   a hub, defining an axis of rotation, and a plurality of backswept aerodynamic blades carried on the surface of said hub and defining air passages between adjacent blades,

   wherein each of said air passages is defined by from one to three solid die inserts which can be inserted between and pulled from between said blades without deformation of said dies or blades.

   * * *

7. A cast titanium centrifugal compressor wheel comprising:

   an annular hub defining an axis of rotation, and

   a plurality of backswept aerodynamic blades, each of said blades including a leading edge, an outer edge adapted for close passage to a compressor housing, and a trailing edge,

   wherein said leading edge is substantially a straight edge,

   wherein said blades are designed such that a compound die insert comprising first and second solid die inserts defining one air passage between adjacent blades can be inserted between said adjacent blades, and wherein said first and second die inserts can be retracted along a radial or curved path without deformation of said blades or dies.

'347 Patent, Col. 10, lines 26-35, Col. 10, line 61 to Col. 12, line 3 (emphasis added).

The independent claims of the '556 Patent recite methods for manufacturing a "titanium centrifugal compressor wheel."

These independent claims provide as follows:

1. A method for manufacturing a titanium centrifugal compressor wheel, said method comprising:

   introducing a sacrificial material into a die comprised of a plurality of rigid die inserts (20) to form a compressor wheel pattern comprising a hub (1) defining an axis of rotation and backswept aerodynamic blades (4,5) carried on said hub,

   extracting said die inserts (20) radially or along a curve to expose said compressor wheel pattern,

   forming a mold by a lost wax process around said compressor wheel pattern (21),

   forming said titanium compressor wheel by investment casting in said mold.

   * * *

- 4828 -
7. A method for manufacturing a cast titanium centrifugal compressor wheel comprising:

designing a compressor wheel pattern shape with an annular hub (1) and a plurality of backswept blades (4,5), each blade including a leading edge (18), an outer edge adapted for close passage to a compressor housing, and a trailing edge (16), wherein said leading edge (18) is substantially a straight edge, and wherein said blades (4,5) define air passages between adjacent blades and are contoured such that each of said air passages between adjacent blades can be defined by not more than three die inserts (20) inserted between adjacent blades and respectively retractable along a radial or curved path by an automated process,

forming a pattern of said compressor wheel by introducing a sacrificial material into a die comprised of a plurality of rigid die inserts (20),

automatically extracting said rigid die inserts (20) radially or along a curve to expose said compressor wheel pattern,

forming a mold by a lost wax process around said compressor wheel pattern (21),

forming said titanium compressor wheel by investment casting in said mold.

'556 Patent, Col. 10, line 57 to Col. 12, line 17 (emphasis added).

The independent claims of the '949 Patent provide for methods for manufacturing an air boost device and a turbocharger. These independent claims do not refer to a "titanium centrifugal compressor wheel," but rather only to a "titanium compressor wheel" or simply "said compressor wheel":

1. A method for manufacturing an air boost device, said method comprising:

introducing a sacrificial material into a die comprised of a plurality of rigid die inserts (20) to form a compressor wheel pattern comprising a hub (1) defining an axis of rotation and backswept aerodynamic blades (4,5) carried on said hub,

extracting said die inserts (20) radially or along a curve to expose said compressor wheel pattern,

forming a mold by a lost wax process around said compressor wheel pattern (21),

forming a titanium compressor wheel by investment casting in said mold, and

mounting said titanium compressor wheel within a compressor housing.

* * *

10. A method for manufacturing a turbocharger, comprising:

designing a compressor wheel pattern shape with an annular hub (1) and a plurality of backswept blades (4,5), each blade including a leading edge (18), an outer edge adapted for close passage to a turbocharger compressor housing, and a trailing edge (16), wherein said blades (4,5) define air passages between adjacent blades and are contoured such that each of said air passages between adjacent blades can be defined by not more than three die inserts (20) inserted between adjacent blades and respectively retractable along a radial or curved path by an automated process,

forming a pattern of said compressor wheel by introducing a sacrificial material into a die comprised of a plurality of rigid die inserts (20),

extracting said rigid die inserts (20) radially or along a curve to expose said compressor wheel pattern, forming a mold by a lost wax process around said compressor wheel pattern (21),

forming a titanium compressor wheel by investment casting in said mold, and
mounting said compressor wheel within said turbocharger compressor housing.

While the parties agree that a "titanium centrifugal compressor wheel" is a circular rotating component which (a) draws air in axially, (b) accelerates air centrifugally, and (c) discharges air radially, the parties disagree as to whether this term is synonymous with the term "titanium compressor wheel." BorgWarner contends that "titanium compressor wheel" is used interchangeably throughout the patents with the term "titanium centrifugal compressor wheel" and therefore these terms should be construed in the same manner. BorgWarner further argues that both "titanium compressor wheel" and "titanium centrifugal compressor wheel" should be limited further to a compressor wheel which (1) operates within an air boost device and (2) is made predominantly from titanium. [Doc. 52 at 3; Doc. 57-2 at 12-23; Doc. 62 at 4-6]. Honeywell argues, on the other hand, that the patents expressly distinguish the terms "titanium compressor wheel" and "titanium centrifugal compressor wheel," and therefore it would be error to construe the terms as being synonymous. Honeywell further argues that it would be improper to require the claimed compressor wheel to be operated within an air boost device, because that limitation is not recited in the claims. Additionally, Honeywell argues that BorgWarner's proposed limitation of these terms to a compressor wheel comprised predominantly of titanium is inconsistent with the specification. [Doc. 58-2 at 11-12; Doc. 63 at 16-17, 24-25].

a. Are the terms "titanium centrifugal compressor wheel" and "titanium compressor wheel" interchangeable?

Examine the language of the claims themselves, the Court notes that the terms "titanium compressor wheel" and "compressor wheel" are used throughout the claims of the '347 Patent and the '556 Patent to refer to a "titanium centrifugal compressor wheel." For example, independent Claim 1 of the '347 Patent recites a "titanium centrifugal compressor wheel." '347 Patent, Col. 10, line 26. This limitation is referenced in the following dependent claim as a "titanium compressor wheel as in claim 1 …." Id. at Col. 10, line 37. In Claim 7 of the '556 Patent, a method is described for the manufacturing of "a cast titanium centrifugal compressor wheel." '556 Patent, Col. 11, line 15. In the following dependent claim, the cast titanium centrifugal compressor wheel of independent Claim 7 is referred to as "said compressor wheel." Id. at Col. 12, line 7. In the '949 Patent, however, a distinction clearly is made between the term "titanium compressor wheel" and "titanium centrifugal compressor wheel." Claim 1 of the '949 Patent describes a method for manufacturing an air boost device, "said method comprising … forming a titanium compressor wheel by investment casting …." '949 Patent, Col. 10, lines 38-51. In the following dependent claim, a method is claimed "wherein said compressor wheel is a centrifugal compressor wheel adapted for drawing air in axially, accelerating said air centrifugally, and discharging air radially." Id. at Col. 10, lines 54-57 (emphasis added). This claim language clearly indicates that a centrifugal compressor wheel is a type of compressor wheel. In other words, while a "titanium centrifugal compressor wheel" may be a "titanium compressor wheel," a "titanium compressor wheel" need not necessarily be centrifugal. Accordingly, the plain language of the claims does not support BorgWarner's contention that these terms are synonymous and interchangeable.

BorgWarner's own expert recognized the distinction between these terms, noting that the term "titanium compressor wheel" could refer to either a centrifugal compressor wheel or an axial compressor wheel:

Q. And what about the term "titanium compressor wheel" without the word "centrifugal" in there? What does that mean to you?

A. Oh, I see. Well, it's more of a generic term. That is, centrifugal is a subset of compressor wheels.

Q. So a titanium compressor wheel could be axial?

A. Yes.

[Deposition of John K. Thorne ("Thorne Dep."), Doc. 58-14 at 10].

For these reasons, the Court concludes that the terms "titanium compressor wheel" and "titanium centrifugal compressor wheel" are not synonymous.

b. Must the compressor wheel be operated within an air boost device?
In determining whether the patent claims require the subject compressor wheel to be operated within an air boost device, the Court first examines the language of the claims themselves. While the claims of the '949 Patent specifically contemplate the use of a compressor wheel within an air boost device, see '949 Patent, Claims 1 and 10, the claims of the '347 Patent and '556 Patent do not. The '347 Patent claims are directed to the compressor wheel itself, while the '556 Patent claims are directed to the method of manufacturing the compressor wheel. Only the claims of the '949 Patent, which are directed to the manufacture of an air boost device comprised of, among other things, a compressor wheel, can be read as requiring the use of the compressor wheel within an air boost device. The plain language of the claims therefore do not support a limitation of the terms "titanium centrifugal compressor wheel" and "titanium compressor wheel" in each of the patents-in-suit solely to compressor wheels used in an air boost device.

Turning now to the other intrinsic evidence of record, the Court notes that the specification expressly provides that "the present invention concerns a titanium compressor wheel for use in an air boost device." '347 Patent, Col. 1, lines 5-10 (emphasis added); Id. at Col. 1, line 64 to Col. 2, line 12 (discussing use of compressor wheel in engine exhaust systems). Such statements do not, however, necessarily limit the scope of the patents to compressor wheels used in air boost devices. "Absent a clear disclaimer of particular subject matter, the fact that the inventor may have anticipated that the invention would be used in a particular way does not mean that the scope of the patent is limited to that context." Northrop Grumman Corp. v. Intel Corp., 325 F.3d 1346, 1355 (Fed. Cir. 2003). The specification in the present case does not disavow any embodiment other than one operating within an air boost device, nor does it suggest that the subject invention must always be used in that fashion. Indeed, the specification explicitly provides, in pertinent part, as follows:

Although this invention has been described in its preferred embodiment with a certain [amount] of particularity with respect to an automotive internal combustion compressor wheel, it is understood that the present disclosure of the preferred form has been made only by way of example and that numerous changes in the details of structures and the composition of the combination may be resorted to without departing from the spirit and scope of the invention.

't347 Patent, Col. 10, lines 10-23. For these reasons, the Court concludes that, notwithstanding the repeated references to the anticipated use of the subject compressor wheel in an air boost device throughout the specification, the terms "titanium centrifugal compressor wheel" and "titanium compressor wheel" are not construed as being limited to a wheel operated within an air boost device.

c. Must the compressor wheel be "comprised predominantly of titanium"?

In the specification, the inventors explicitly defined the term "titanium compressor wheel" as "a compressor wheel comprised predominantly of titanium, and includes titanium alloys, preferably light weight alloys such as titanium aluminum alloy." '347 Patent, Col. 6, lines 44-47 (emphasis added). BorgWarner argues that the reference to "titanium alloys" in this passage is designed to provide the reader of an example of a composition "comprised predominantly of titanium." Thus, BorgWarner contends, this phrase requires the titanium compressor wheel to be comprised predominantly of titanium or an alloy that is comprised predominantly of titanium. [Doc. 57-2 at 12-15]. Honeywell argues, on the other hand, that this phrase should be construed to mean that the titanium compressor wheel can be comprised predominantly of titanium, but that it can also be made of alloys, and that these alloys need not necessarily be predominantly titanium. [Doc. 58-2 at 26-27; Doc. 63 at 24-25].

The inventors' use of the phrase "and includes titanium alloys" within the definition of "titanium compressor wheel" is admittedly not the model of clarity. Using basic principles of grammar and sentence construction, it appears to the Court that the phrase "and includes titanium alloys" was included to modify the term "titanium." In other words, the phrase "and includes titanium alloys" indicates a subset of "titanium," the material which must be used predominantly in the manufacture of the compressor wheel. Thus, a plain reading of this definition requires that the compressor wheel be comprised predominantly of either (1) pure titanium or (2) a titanium alloy.

The Court's construction of this term is supported by the prosecution history of the '347 Patent. The Patent Examiner initially rejected Claim 8 as being indefinite. Specifically, the Patent Examiner noted that the claim recited that the compressor wheel is "selected from titanium" when the claim already recited that the compressor wheel is titanium. In response, the inventors stated as follows:
Applicants submit that the term "titanium compressor wheel" is understood in the art as referring to a wheel formed primarily of titanium, i.e., either a titanium alloy or pure titanium, though overwhelmingly in practice the alloy is used. The term is so defined in paragraph 00037 of the present specification.

Having determined that the titanium compressor wheel may be comprised predominantly of (1) pure titanium or (2) a titanium alloy, the Court turns to the issue of whether the "titanium alloy" used itself must be "comprised predominantly of titanium." Examining the language of the claims, the Court notes that in each instance where the claims recite the specific titanium composition of the alloy used, the claims expressly require a material composed predominately of titanium. For example, in both Claim 13 and Claim 14 of the '949 Patent, which recite methods of manufacturing a compressor wheel formed of a titanium alloy, the titanium alloy specified is one in which titanium is the element of highest concentration:

13. A method as in claim 12, wherein said titanium alloy comprises 85-95% titanium, 2-8% aluminum, and 2-6% vanadium.

14. A method as in claim 12, wherein said titanium alloy comprises approximately 90% titanium, 6% aluminum, and 4% vanadium.

'949 Patent, Col. 12, lines 16-20 (emphasis added).

Additionally, Claims 6 and 9 of the '556 Patent make reference to a "titanium-aluminum alloy." As noted by BorgWarner's expert, Dr. John K. Thorne, the fact that titanium is listed before aluminum in the naming of this alloy indicates to one of ordinary skill in the art that titanium is the element of highest concentration. [Declaration of Dr. John K. Thorne ("Thorne Decl."), Doc. 55 at P30 ("the first named constituent element is the element of highest concentration in the alloy").]

Dr. Thorne further explained in his deposition that the most common titanium alloys are ones in which titanium is clearly and unambiguously the dominant element -- usually in excess of 90% of the composition. [Thorne Dep., Doc. 57-12 at 3]. Dr. Thorne's opinion is confirmed by Marks' Standard Handbook for Mechanical Engineers (9th ed. 1987), which contains a table listing the typical compositions of titanium alloys. In all of these alloys, titanium is the greatest constituent ingredient by weight. [Doc. 57-14 at 4].

Honeywell urges the Court to adopt the definition set forth in The New Oxford American Dictionary 44 (2001), which defines "alloy" as a "metal made by combining two or more metallic elements, esp. to give greater strength or resistance to corrosion." Honeywell contends that nothing in this definition requires an alloy to be comprised predominantly of one metal. [Doc. 58-2 at 27]. Honeywell's reliance on a definition from a general usage dictionary, however, is not persuasive in light of Dr. Thorne's testimony. "[A] general-usage dictionary cannot overcome credible art-specific evidence of the meaning or lack of meaning of a claim term." Vanderlande Indus. Nederland BV v. Int'l Trade Comm'n, 366 F.3d 1311, 1321 (Fed. Cir. 2004).

For the foregoing reasons, the Court concludes that the term "titanium centrifugal compressor wheel" should be construed as a centrifugal compressor wheel comprised predominantly of either pure titanium or a titanium alloy. The term "titanium compressor wheel" should be construed as a compressor wheel comprised predominantly of either pure titanium or a titanium alloy. The term "titanium alloy" is construed to mean an alloy wherein titanium is the greatest constituent ingredient by weight. The term "titanium-aluminum alloy" is construed to mean a metal alloy that is comprised of titanium and aluminum, wherein titanium is the greatest constituent ingredient by weight.
transferred beverage container to a delivery port of the vending machine . . . " '930 Patent, cl. 1 (emphasis added). The parties dispute the distance that the robotic assembly or beverage container must travel to meet the claim limitation. The answer to this question depends on (1) whether the claim limitation requires the movement of either the robotic assembly or beverage all the way "to a delivery port" and (2) whether "delivery port" refers to a general area or a more defined opening in the machine. The issues are interrelated. How far the robotic assembly or beverage must travel depends, in part, on the breadth of the construction of "delivery port." 2 The court is not persuaded by Royal or SVA's argument concerning "delivery port." SVA agrees with Crane's spatial concept, but would unnecessarily limit the delivery port to the area that the customer can reach. Under this construction, however, subsequent method steps in the claim would appear to be redundant. See '930 Patent, cl. 1 ("presenting the carried beverage container at the delivery port for customer removal from the vending machine . . . ") (emphasis added)). For its part, Royal defines "delivery port" in a structural manner. Royal's construction, however, discounts the language of the specification that seems to define the product delivery port in more general terms. See e.g. '930 Patent, col. 3, ll. 22-23 ("carrying the captured container to a product delivery area or port." (emphasis added)); see also id. at col. 1, l. 38, col. 2, l. 20, 61 (each discussing a "delivery area."). Accordingly, the "delivery port" is more than a physical opening in the vending machine. The court defines "delivery port" (and related terms) as "the area in the vending machine from which containers/beverages/products may be retrieved by the customer."

2 Crane agrees to a narrow construction of "to a delivery port" so long as the court adopts a broad construction of "delivery port." SVA agrees to Crane's construction of "delivery port" so long as the construction includes "by customers" at the end.

The remaining issue is whether "to a delivery port," means the same thing as "toward a delivery port." The patentee explicitly chose different language in the claims, and the doctrine of claim differentiation counsels against adopting Crane's construction. Compare '180 Patent, cl. 33 with '180 Patent, cl. 34. "To a delivery port" means that the product reaches the delivery port. "Toward a delivery port" means that the product simply needs to travel in the direction of the delivery port.

Claim 1 of the '447 patent is representative of the term at issue. 3 With the disputed term in bold, Claim 1 states:

A polycrystalline diamond element comprising a body of bonded diamonds with a working surface, wherein a first volume of the body remote from the working surface contains a catalyzing material, a second volume of the body adjacent to the working surface is substantially free of the catalyzing material to a depth from the working surface, wherein said bonded diamonds exhibit a thermal characteristic such that a 950 degree C. temperature at the working surface results in a temperature of less than 750 degrees C. at the depth.

3 The '098, '137, and '447 patents claim and specifications are similar. For simplicity, the Court will cite to the '447 patent generally.

Baker Hughes proposes "to a distance of at least 0.1 mm measured perpendicularly from the top of each part of each working surface." ReedHycalog contends that this phrase does not need to be construed. To support its argument, Baker Hughes points to the '098 patent specification, which reads: "[t]herefore, for the types of heat input common in cutting elements 10, a 0.1 mm depth is the critical depletion depth from the working surface . . . " Pat. No. '098 col. 10: 43-45. However, the previous sentence in that specification states, "[a]s can be seen in curve A in the graph of Fig. 10 there is a dramatic increase in the wear index result of cutting elements 10 when the catalyzing material 64 depletion depth approaches 0.1 mm." Id. at 10:40-42 (emphasis added). In addition, the '137 patent specifically discusses other leach depths.
Clearly this language contemplates improved wear index at various levels of leaching, not solely 0.1 mm. Baker Hughes' proposed construction would improperly limit the claim to the preferred embodiment. The phrase is easily understood and does not require construction.

4 The '137 patent specification states

... it is also believed that a distance D of less than 0.1 mm could provide approximately the same wear index in a cutting element with a diamond density of the body approaching 99% as the 0.2 mm to 0.3 mm D distance in a body with 85% to 90% diamond volume density.

To a Depth

The Patents-in-Suit contain the term "to a depth." ReedHycalog contends the term does not require construction. Defendants argue "to a depth" means "to a distance of a minimum of 0.1 mm measured perpendicularly from the top of each part of each working surface." The parties' constructions raise two issues: (1) whether the leach depth has a minimum of 0.1 mm; and (2) whether the depth is measured perpendicularly from the top part of each working surface. The Court in Tyler I addressed the first dispute, rejected Defendants' construction, and concluded the term did not require construction. Defendants do not raise any new or persuasive arguments in this case.

The Patents-in-Suit Do Not Require a Minimum Leach Depth of 0.1 mm

The Court in Tyler I addressed and rejected Defendants' arguments that the specifications' statement that "a 0.1 mm depth is the critical depletion depth from the working surface" mandated a minimum leach depth of 0.1 mm. Tyler I Claim Construction Opinion & Order, 10-11. For the reasons delineated in that opinion, the Court rejects Defendants' attempt to limit the claims.

The claims that contain the "to a depth" limitation and do not specify a particular depth appear in the Thermal Characteristic Patents, which generally claim a leach depth such that a 950 [degree] C temperature at the PCD element's working surface results in a temperature of less than 750 [degree] C at the depth. E.g., '447 Patent, col. 14:24-33. Thus, the claims themselves define the leach depth by the resulting thermal gradient and do not require a minimum leach depth of 0.1 mm.

Fig. 10 of the Thermal Characteristic Patents depicts the relationship between leach depth and wear index, where a higher wear index corresponds to a greater ability of the PCD element to withstand heat. Id. at Fig. 10, col. 10:33-36. The accompanying portion of the specifications indicate it is improper to read in a required minimum leach depth of 0.1 mm.

The specifications indicate the depth required to achieve the claimed thermal gradient is a function of the leaching process, the crystal size, and the amount of inter-crystal bonding, among other variables. Id. at col. 9:56-63 (stating leach depth required to achieve the reduced thermal degradation depends upon the method used to deplete the catalyzing material); id. at col. 10:38-57 (stating the difference between PCD elements that create curves A and B is that the PCD element from curve B was leached using a more economical process); id. at col. 11:11-13 (stating that temperature gradient between leached and unleached portions of the PCD element depends upon the crystal size and the amount of inter-crystal bonding). Therefore, a particular diamond crystal size, the amount of interstitial bonding that resulted from forming the PCD element, and a particular leaching process could create a PCD element with a steeper wear index versus leach depth curve than curve A depicted in Fig. 10. This steeper curve would allow the resulting PCD element to achieve the claimed thermal gradient at a leach depth of less than 0.1 mm. Thus, while 0.1 mm may be the "critical depletion depth" for PCD elements affiliated with curve A, the critical depletion depth for PCD elements affiliated with a steeper curve would be less than 0.1 mm.
Further, nothing in the Thermal Gradient Patents indicates the claims are limited to PCD elements affiliated with curve A or B. Thus, the term "to a depth" covers partially leached PCD elements affiliated curves that achieve the claimed thermal gradient at shallower leach depths. 10

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

10 In addition, the ’137 Patent confirms that the claims do not require a minimum leach depth of 0.1 mm:

It is believed, however, that as the volume density of the diamond in the body 8 increases from the 85%-90% range to the 95%-99% range, the distance D needed to produce a particular wear index will decrease. Therefore, it is also believed that a distance D of less than 0.1 mm could provide approximately the same wear index in a cutting element with a diamond density of the body approaching 99% as the 0.2 mm to 0.3 mm D distance in a body with 85% to 90% diamond volume density.

The Ordinary Meaning of "Depth" Requires a Perpendicular Measurement

The claims require a portion of the PCD body to be substantially free of the catalyzing material to a depth from the working surface or cutting surface. E.g., ’447 Patent, col. 14:24-33; ’033 Patent, col. 14:26-34. Some of these claims require this region to extend to a specified depth, such as 0.1 mm. E.g., ’985 Patent, col. 14:21-31 (claiming a PCD element comprising a body of bonded diamond crystals and a working surface on the body wherein "a second volume of the body adjacent to the working surface is substantially free of the catalyzing material . . . , wherein the second volume extends to a depth of at least 0.1 mm from the working surface").

The ordinary meaning of depth requires a perpendicular measurement from a reference point, in this case the working surface or cutting surface depending on the claim. Nothing in the Patents-in-Suit indicates a departure from this ordinary meaning. Nothing in the Patents-in-Suit, however, requires the measurement to be from the top of all working surfaces.

The Court has resolved the parties' dispute. A lay jury will understand the term "to a depth," and it does not require construction.

II

A. As noted, the claim requires "heating the resulting batter-coated dough to a temperature in the range of about 400 degrees F. to 850 degrees F." These are ordinary, simple English words whose meaning is clear and unquestionable. There is no indication that their use in this particular conjunction changes their meaning. They mean exactly what they say. The dough is to be heated to the specified temperature. Nothing even remotely suggests that what is to be heated is not the dough but the air inside the oven in which the heating takes place. Indeed, the claim does not even refer to an oven.

The problem is that if the batter-coated dough is heated to a temperature range of 400 degrees F. to 850 degrees F., as the claim instructs, it would be burned to a crisp. Instead of the "dough products suitable for freezing and finish cooking to a light, flaky, crispy texture," 290 patent, col. 2, ll. 11-12, which the patented process is intended to provide, the resultant product of such heating will be something that, in the words of one of the attorneys in this case, resembles a charcoal briquet. To avoid this result and to insure that the patented process can accomplish its stated objective, Chef America urges us to interpret the claim as if it read "heating the . . . dough at a temperature in the range of," i.e., to apply the heating requirement to the place where the heating takes place (the oven) rather than the item being heated (the dough).

This court, however, repeatedly and consistently has recognized that courts may not redraft claims, whether to make them
operable or to sustain their validity. See, e.g., Allen Eng'g Corp. v. Bartell Indus., Inc., 299 F.3d 1336, 1349 (Fed. Cir. 2002); Elekta Instrument S.A. v. O.U.R. Scientific Int'l, Inc., 214 F.3d 1302, 1308-09 (Fed. Cir. 2000); Process Control Corp. v. Hydreclaim Corp., 190 F.3d 1350, 1357 (Fed. Cir. 1999); Rhine v. Casio, Inc., 183 F.3d 1342, 1345 (Fed. Cir. 1999); Quantum Corp. v. Rodine, PLC, 65 F.3d 1577, 1584 (Fed. Cir. 1995); Becton Dickinson & Co. v. C.R. Bard, Inc., 922 F.2d 792, 799 n.6 (Fed. Cir. 1990). Even "a nonsensical result does not require the court to redraft the claims of the ['290] patent. Rather, where as here, claims are susceptible to only one reasonable interpretation and that interpretation results in a nonsensical construction of the claim as a whole, the claim must be invalidated." Process Control Corp., 190 F.3d at 1357. "Where, as here, the claim is susceptible to only one reasonable construction, the canons of claim construction cited by [Chef America] are inapposite, and we must construe the claims based on the patentee's version of the claim as he himself drafted it." Id.

Thus, in accord with our settled practice we construe the claim as written, not as the patentees wish they had written it. As written, the claim unambiguously requires that the dough be heated to a temperature range of 400 degrees F. to 850 degrees F.

B. Although "a patentee can act as his own lexicographer to specifically define terms of a claim contrary to their ordinary meaning," id. (citing Digital Biometrics v. Identix, Inc., 149 F.3d 1335, 1344 (Fed. Cir. 1998)), we discern nothing in the claims, the specification, or the prosecution history that indicates that the patentees here defined "to" to mean "at." To the contrary, the prosecution history suggests that the patentees intentionally used "to" rather than "at" in drafting the temperature requirements of the claim.

As originally drafted, Claim 1, which is involved here, did not contain any temperature limitations. It stated: "heating the resulting batter-coated dough to first set said batter and then subsequently melt said shortening flakes, whereby air cells are formed in said batter and the surface of said dough." Original Claim 6 however, provided for ":[a] process according to Claim 1 wherein said resulting batter-coated dough is heated to a temperature within the range of about 400 degrees F to 850 degrees F for about from 10 seconds to 5 minutes." The original application also contained the description of the baking process set forth in Part I.A, above, which involved "quickly heating [the batter] to a temperature in the range of about 400 degrees F to 850 degrees F" for a specified time range, and the first example, which stated that the dough product will be baked in a particular type of oven "at" a temperature of 680 degrees F. to 850 degrees F.

The examiner initially rejected all the claims under the first paragraph of 35 U.S.C. § 112 (2000) as non-enabling for various reasons, including that "any and [all] heating steps are not enabled, e.g. insignificant or excessive." In response, the patentees amended Claims 1 and 8 to add the limitation of "heating the resulting batter-coated dough to a temperature in the range of about 400 degrees F. to 850 degrees F. for a period of time ranging from about 10 seconds to 5 minutes to first set said batter and then subsequently melt said shortening flakes, whereby air cells are formed in said batter and the surface of said dough." (underlined words added by amendment).

In formulating the amendment to the claims to specify the temperature limitation, the patentees had two models before them: the heating "to" limitation of the specification and original Claim 6 or the heating "at" limitation of the example. They chose the "to" limitation which, as we have shown, plainly and unequivocally refers to the temperature to which the dough and not the air in the oven will be heated. It thus appears that the patentees consciously selected "to" rather than "at." There is nothing to indicate that in doing so they intended "to" to mean "at."

Chef America does not contend that the patentees' use of "to" rather than "at" was a draftsman's mistake. The patentees made no attempt to have such an error corrected, either by obtaining a certificate of correction from the Patent and Trademark Office pursuant to 35 U.S.C. § 255, or by action of the district court. Cf. Novo Indus. v. Micro Molds Corp., 350 F.3d 1348 (Fed Cir. 2003). To the contrary they argue only that "to" should be construed to mean "at" because otherwise the patented process could not perform the function the patentees intended. As we have noted, however, we have repeatedly declined to rewrite unambiguous patent claim language for that reason.

C. Chef America criticizes the district court for failing to construe the claims as one of ordinary skill in the art would do. It cites a declaration of its baking expert, Mr. Lehmann, the Director of Baking Assurance of the American Institute of Baking, that "the limitation in claims 1 and 8 'heating the resulting batter-coated dough to a temperature in the range of about 400 degrees F to 850 degrees F' (and the similar limitation in claim 6 specifying a range of 680 degrees F to 850 degrees F) mean to me, as a person of ordinary skill in the art, that the batter-coated dough is placed in an oven that has been set to a
temperature in the range of about 400 degrees F to 850 degrees F, and remains in the oven for the period within the time range recited in the claim." Mr. Lehmann also there opined that the two examples, which use the word "at," and "are the only ones given in the patent, show that the 'heating' limitation relates to oven temperature, not product temperature." Mr. Lehmann also quoted the language from the specification containing the temperature limitation described above and stated: "as a person of ordinary skill in the art in 1987, when the '290 patent application was filed, I would read this text as meaning that the product is placed in an oven whose temperature has been set in the range of about 400 degrees F to 850 degrees F. It was well known in 1987, and still is well known, that raising the temperature of a dough product itself to such high temperatures would result in an unusable product."

The district court rejected this contention and so do we. As the district court pointed out, "Lehmann's declaration, however, further supports [its] conclusion that the claim words themselves do not have special meaning to one skilled in the art of baking. Instead, Lehmann's declaration makes it clear that, while he may read the claim in accordance with the construction proffered by plaintiff, he does so not because the words have special meaning to him, but because it 'is well known[ ] that raising the temperature of a dough product itself to such high temperatures would result in an unusable product.'" Mr. Lehmann did not explain how the word "to" in the claim could be read to mean "at," or even state that persons of ordinary skill in the baking art would so do.

This argument of Chef America is but a restatement of its basic contention that unless we rewrite the claim, the patented process cannot perform its intended function. We have already declined, however, to take such action, and we follow the same course in response to this additional version of the argument.

We initially consider the proper claim meaning and scope. Amazon.com, Inc. v. Barnesandnoble.com, Inc., 239 F.3d 1343, 1351 (Fed. Cir. 2001). Although neither the Board nor Icon specifically argues for any particular construction of the gas spring limitation, each party's obviousness argument turns on the breadth of that limitation. During reexamination, as with original examination, the PTO must give claims their broadest reasonable construction consistent with the specification. In re Am. Acad. of Sci. Tech Ctr., 367 F.3d 1359, 1364 (Fed. Cir. 2004). Therefore, we look to the specification to see if it provides a definition for claim terms, but otherwise apply a broad interpretation. As this court has discussed, this methodology produces claims with only justifiable breadth. In re Yamamoto, 740 F.2d 1569, 1571 (Fed. Cir. 1984). Further, as applicants may amend claims to narrow their scope, a broad construction during prosecution creates no unfairness to the applicant or patentee. Am. Acad., 367 F.3d at 1364.

The claims at issue recite "a gas spring . . . to assist in stably retaining said tread base." As the Board noted, "claim 1 does not limit the degree or manner in which the gas spring" assists in stably retaining. Board Decision, slip op. at 24. Icon, without arguing for any particular construction, takes the position that the gas spring must provide a force continuing to urge the mechanism closed when in the closed position. The specification of the '624 patent provides only minimal discussion of the gas springs. It describes a "lift assistance assembly," which in the illustrated embodiment includes a gas spring to provide force to at least partially support the weight of the tread base. '624 patent, col. 15, ll. 3-25. When claiming the gas spring, the application makes no reference to lift assistance, only stable retention of the tread base.

The specification provides little further regarding a definition of "stably retain." It describes the treadmill's folding action, such that the center of gravity of the tread base passes over the pivot point to "stably retain" the base. Id. at col. 12, ll. 30-34. Accordingly, gravity creates a stable closed position: the gas spring claimed must only "assist" in stably retaining the tread base. Because Icon could have amended its claims to more clearly define "stably retain" and did not do so, it now must submit to the Board's interpretation. With little guidance from the specification, the Board's construction properly represents the broadest reasonable construction. Although the Board did not set out the specific construction for Icon's claim, it did so to the extent required. Indeed, an infringement or invalidity analysis provides the context for claim construction. See Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 442 F.3d 1326-27 (Fed. Cir. 2006). We therefore analyze the Board's factual findings and conclusion of obviousness while considering that Icon's claims encompass everything reasonably seen to assist in stably retaining the tread base.
With a wick to convey a combustible liquid to the burner

The term "combustible liquid" is a required limitation of the claim. Defendants, on the other hand, argue that the combustible liquid prominently referenced in claim 1 must be construed as a required limitation on the claim. Defendants point to the prosecution history, including a response to an Office Action by the Patent Office dated May 3, 2002, wherein the Applicants for what became the '061 patent amended certain claims because of substantive rejections based upon the prior art. See Doc. No. 58, Ex. 3, at PB0238. Specifically, Defendants cite the Applicants' statement that "claim 12 has been amended to further define features relating to the combustible liquid penetrating into the pores of the burner . . ." as support that features relating to the liquid comprised a patentable distinction over the cited prior art. Id.

While the Court disagrees with Defendants that the Applicants distinguished their invention based upon the combustible liquid, the Court does find that the combustible liquid comprises a required limitation in claim 1. French Patent Publication FR 2 530 144 was applied by the examiner during prosecution of the patent which matured into the '061 patent. The examiner initially rejected claim 12 of the application, which became claim 1 of the '061 patent, on the basis that the invention was made to modify the burner of FR 2 530 144 to incorporate the annular groove of EPO 0 277 875 as the structure of the burner, including the annular cavity that serves to prevent encrustation of the wick due to carbon particle build-up. Id. at PB0252. In response to the office action, the Applicants specifically claimed that the "catalytic combustion burner as defined in amended claim 12" was distinguished from the prior art "by the presence of at least one open channel located in the upper part of the burner . . ." Id. at PB023 8-39. Thus, in accordance with the Applicants' position during prosecution, the Court finds that the open channel catalytic combustion burner distinguished the invention over the apparatus disclosed in FR 2 530 144. Nevertheless, the fact that Applicants amended claim 12 to further define "features relating to the combustible liquid penetrating into the pores of the burner" lends support to the idea that the liquid is a limitation.

Claim 1 of the '061 patent references the "combustible liquid" twice within phrase 4: (1) "a wick to convey a combustible liquid;" and (2) "said combustible liquid penetrating into the pores of said burner's porous material. . ." '061 patent, claim 1, 5:37-39. While it is true, as Plaintiffs argue, that there is nothing new or unique about the combustible liquid mixture in the context of the present invention, it is also true that the claim language references the liquid and makes it clear that the liquid performs some function, i.e., being conveyed by the wick and "penetrating" into the pores of the stone. Id. Further, even though the catalytic combustion burner can burn in the absence of combustible liquid or when the burner burns the last quantities of combustible liquid remaining in the flask, it is undeniable that the combustible liquid is an integral part of the invention, as the invention will not work absent "said combustible liquid penetrating into the pores of said burner's porous material."

Accordingly, the Court finds that the "liquid" referenced in claim 1 is itself part of the claimed invention and is, therefore, a required limitation of the claim.
10. Fresh Water Added To Cool Said Fabric

The meaning of the phrase "fresh water is added to cool said fabric" is in dispute. It appears in the following context: "prior to draining said lesser concentrated detergent solution from said wash chamber, fresh water is added to cool said fabric" ('370 patent, claims 4.11.)

Whirlpool argues for the following construction: "This claim element means that prior to draining, fresh water is added to the washer and the fresh water has the effect of cooling fabric in the washer, regardless of the reason for added the fresh water."

LG seeks the following construction: "Fresh water (i.e., not a solution of water and another additive) is added for the intended purpose of cooling the fabric and not added for other purposes."

The primary dispute with respect to this phrase is whether it establishes a limitation that fresh water be added with the intention or purpose of cooling the fabric. The Federal Circuit held in Dow Chem. Co. v. Mee Indus., 341 F.3d 1370, 1380 (Fed. Cir. 2000) that "the motive of the accused infringer when performing a claimed method is simply not relevant." Based on Dow, Whirlpool argues that even if water is added for an entirely different reason than to cool the fabric, infringement would not be avoided because the reasons why water might be added are irrelevant. However, Whirlpool's reliance on Dow is misplaced. Dow was a patent infringement decision, rendered after the claims had been construed, which stands for the proposition that a person who practices a claimed method infringes regardless of the person's subjective intent or motive. The present action, in contrast, remains at the claim construction stage, where the Court's task is not to determine infringement, but rather the proper interpretation of the claims. Dow thus has no bearing on the issue now before the Court.

The Court concludes that the plain and ordinary meaning of the phrase is that the purpose clause, "to cool said fabric," necessarily modifies the clause describing the action, "fresh water is added." No other construction of the language makes sense. Thus, the Court construes the language to contain LG's proposed limitation and rejects Whirlpool's attempt to delete it from the claim. Intrinsic evidence only serves to confirm the purpose limitation. The patent specification describes the cooling purpose for the addition of fresh water: "In some embodiments, where extremely high temperatures are used during the tumble wash, water is added at the end of the tumble wash cycle to cool the clothes load, and the wash water." ('370 Patent, col. 8, lines 38-41.) (emphasis added) Elsewhere in the patent, Whirlpool discusses the introduction of water for purposes other than cooling the fabric, such as to dispense fabric softener during the spray rinse. ('370 patent, col. 9, lines 36-41.) It is therefore clear that when Whirlpool added the purpose language to the claim, it did so for a reason and meant it to require that the fresh water actually cools the fabric.

Another point of dispute concerns the meaning of "fresh water." Whirlpool says "fresh water" simply refers to water that is added to the washer from outside (i.e., the tap), and what happens to the water once it enters the washer, such as whether it flows through a bleach dispenser or acquires detergent residue, is irrelevant. LG argues that "fresh water" means clear water only, not a solution of water and some other additive or wash water residue. Neither party offers dictionary definitions for the term, and the Court concludes that its meaning is ambiguous and thus looks to intrinsic evidence. In the '370 patent specification, the only disclosed method of adding fresh water is through the detergent or wash additive dispensers, which necessarily means that "fresh water" must be construed in accordance with Whirlpool's proposal, as it would be impossible for "fresh water" as understood by LG to enter the machine. ('370 patent, col. 3, lines 12-24.) The word "fresh" in the claim takes on a meaning something like "new" or "additional" or "more."

Accordingly, the Court construes the phrase "fresh water is added to cool said fabric" as requiring that the water be added for the purpose of cooling the fabric (i.e., the Court adopts LG's proposed construction). However, the term "fresh water" does not mean clear water without any additives or wash residue (i.e., the Court adopts Whirlpool's proposed construction).
To Form A Group Of Shingled Sheets For Stacking

The final question of claim interpretation is the meaning of the phrase "to form a group of shingled sheets for stacking" in claims 9(a) and 13(a). More specifically, the question is whether a physical difference must be created which enables one to discern the first group to be stacked from the second at the point of shingling. The language clearly does require a physically identifiable group of sheets at the point of shingling.

The language "shingling… to form a group of shingled sheets for stacking" requires some basis to distinguish that group from the next. Otherwise there would be no meaning attributed to the phrase. The claim would mean the exact same thing as "shingling said sheets as they pass said location." Any construction which renders substantial language of the claim meaningless is unacceptable. Lantech, Inc. v. Keip Machine Co., 32 F.3d 542, 546 (Fed. Cir. 1994). If there is no physical distinction at the shingling process then the "shingling" cannot be said to form a group in any sense of those words. If, as suggested by plaintiff, the group is formed merely by a counting mechanism then group formation would have nothing to do with the shingling process.

Plaintiff contends that if this reading is accepted even the preferred embodiment would not employ the patented invention because the machine described in the preferred embodiment does not shingle to form a group. More specifically, plaintiff argues, "the group is not formed by shingling the sheets. Rather, the sheets are continuously deposited on the conveyor." However, the fact that sheets are continuously deposited does not mean that the shingling process does not create the group. As previously discussed shingling is the result of a faster conveyor meeting a slower conveyor. The relative speeds of the two conveyors dictate the shingling process. Altering the speed of either conveyor creates a physical change in the shingled sheets which can identify groups.

The preferred embodiment increases the speed of the conveyor below the nip at the time when the last sheet in group one has been shingled and the first sheet of group two is at the nip, thereby physically distinguishing the two groups as part of the shingling process.

The specification explains the patented process and the summary of the invention at column 1 lines 55-60 as follows:

In accordance with another aspect of the invention, the first phase of the discharge cycle includes speeding up of the conveyor downstream of the shingling nip to move the downstream sheets away from those upstream which will be disposed in the next succeeding stack.

Similarly, column 5 lines 10-14 explains the process in the context of the preferred embodiment:

The result is shown in Fig. 11 which shows the first phase of the discharge cycle wherein sections 4, 5 and 6 all speed up, and the increased speed at vacuum section 5 causes the sheets 10 to form shingles which now overlap about fifty per cent instead of about seventy-five per cent. This increase in speed downstream of the shingling nip 21 also pulls the downstream 100 away from the upstream sheets…

Elements 9(a) and (b) of the patent plainly require formation of groups by the speeding up of the lower conveyor which is clearly a component of the shingling process. Hence, the preferred embodiment supports the interpretation of the phrase "to form a group of shingled sheets for stacking" as requiring a physical identification of that group at the point of shingling.

Based upon the construction above it is clear that the defendants' machines do not infringe the '276 patent for at least two reasons. First, the defendants' machines do not shingle to form a group of shingled sheets for stacking. Defendants' machines shingle continuously with no physical distinction between the groups. A group for stacking is identifiable only after the intervention of the interrupt mechanism downstream of the shingling process.

Second, the defendants' machines do not slow "each said separate in-line conveyor in response to passage of the trailing end of said group." The first conveyor after the nip is not slowed in response to the passage of the trailing end but is slowed in response to the activation of the interrupt mechanism. The only evidence in the record is that this event does not correspond with the passage of the trailing end. Furthermore, in defendants' machines with vacuum conveyors the first two conveyors slow simultaneously in response to the interrupt mechanism, not individually in response to the passage of the trailing end of the group as required by the patent claims.
4177

II. The ’276 Patent

Claim 9 of the ’276 patent reads as follows:

In the method of conveying sheets in succession from a first location along a plurality of separate in-line conveyors to a stacker wherein a vertical stack of a predetermined number of sheets is to be formed, and wherein said plurality of conveyors are traveling at the same speed, the steps of:

(a) shingling said sheets as they pass said location to form a group of shingled sheets for stacking,

(b) increasing the speed of said group of shingled sheets,

(c) and slowing each said separate in-line conveyor individually and successively in a downstream direction in response to passage of the trailing end of said group past the end of each respective separate conveyor to thereby slow sheets traveling upstream of said group of sheets.

(emphasis added).

Marquip asserts that so-called Versions 1, 2, 3, and 4 of the Fosber device use the method in claim 9. The parties both rely on a stipulated description of the process used in the accused Fosber devices. Version 2 is the most basic of the Fosber devices. In Version 2, a "shingling nip" continuously shingles sheets onto a first conveyor moving at normal speed. This first conveyor moves the shingled sheets onto a second conveyor, which moves at the same speed. Between the first and second conveyors is an interrupt mechanism. When the trailing end of the last sheet in a predetermined number of sheets has moved past the interrupt mechanism, the mechanism grabs and stops the next sheet. At substantially the same time, two other events also occur: (1) the second conveyor and all other conveyors downstream of the interrupt mechanism speed up, carrying the predetermined number of sheets toward a stacker at the end of the conveyors, and (2) the first conveyor slows down. As soon as the last sheet of the predetermined number of sheets moves off the second conveyor, two more events occur: (1) the second conveyor also slows down to the speed of the first conveyor, and (2) the interrupt mechanism releases the sheets that it had stopped.

Version 4 is the same as Version 2, except that the first conveyor has been replaced with two conveyors, both of which always run at the same speed. Version 1 differs from Version 2 in that the interrupt mechanism is located midway along the second conveyor. When the interrupt mechanism closes, it - the interrupt mechanism itself - moves at the same speed as the first conveyor. In Version 1, the second conveyor behaves exactly the same as in Version 2. Version 3 is the same as Version 1, except that the first conveyor has been replaced with two conveyors, both of which always run at the same speed.

Claim construction is a question of law, which this court reviews de novo. See Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2D (BNA) 1321, 1337 (Fed. Cir. 1995) (in banc), aff’d, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). The district court interpreted the phrase "shingling . . . to form a group of shingled sheets for stacking" to mean that "a physical difference must be created which enables one to discern the first group to be stacked from the second at the point of shingling." In other words, the term "group" means a "physically identifiable group." The Fosber device does not form "physically identifiable groups" until the interrupt mechanism pinches and stops the flow of sheets.

Although the district court reads the claim to include "physically identifiable," those terms appear nowhere in the claim. More importantly, to construe paragraph (a) in this way would prevent claim 9 from reading on the preferred embodiment. A claim interpretation that places the preferred embodiment outside the literal scope of the claims "is rarely, if ever, correct." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583, 39 U.S.P.Q.2D (BNA) 1573, 1578 (Fed. Cir. 1996).

In the preferred embodiment, sheets are continuously shingled as they drop onto a first conveyor. As soon as the last sheet in a predetermined number of sheets has dropped onto the first conveyor, the first conveyor speeds up. This speed change causes the next sheet to shingle on the previous sheet with less overlap than previously shingled sheets. This point in the
process is the first time that the predetermined number of sheets is "physically identifiable." Thus, the process forms this "physically identifiable group" only as a result of increasing the first conveyor's speed. Yet, paragraph (b) requires "increasing the speed of said group." (emphasis added). Thus, the claim requires that the "group" of paragraph (a) must be fully formed before its speed is increased. In sum, using the district court's interpretation, the preferred embodiment does not fall within the scope of the claims.

The most consistent interpretation of "group" is an accumulation of a predetermined number of sheets. This interpretation allows the claim to read on the preferred embodiment. Moreover, with this interpretation, "shingling" does, in a sense, "form a group of shingled sheets for stacking." With each successive sheet that is shingled, the group of shingled sheets continues to form from non-shingled sheets, until the last of a predetermined number of sheets has been shingled. At that point, the process of shingling has completely formed the group of shingled sheets. It should be noted that this interpretation does not cause the limitation "to form a group of shingled sheets for stacking" to have no meaning. What this limitation requires over and above simply "shingling" is that the number of sheets that have been shingled be kept track of so that the process knows when the last sheet in the group has been shingled.

The specification supports this interpretation. It speaks in terms of a predetermined number of sheets, using as an example "100 in number." '276 patent, col. 4, line 2. The specification describes a system of sheet sensors which provide input to "a stacker sheet counter 44 which is set to provide a signal . . . when a preset number of sheets have passed." Id. at col. 4, lines 29-32 (emphasis added). In describing the stack discharge cycle claimed in paragraphs (b) and (c), the specification states:

> During normal conveying of sheets 10 to create a stack, the sheets are . . . shingled by a slow down . . . and maintained at the same speed and shingle overlap . . . . If a stack of 100 sheets is desired, when counter 44 counts 100 sheets, it triggers . . . the stack discharge cycle. During this cycle, all of the sheets 10 downstream from the 100th one counted are moved onwardly in a group to stacker 7 for discharge, while a space is created between the trailing sheet of the downstream 100 and the leading sheet of the next succeeding upstream sheets.

Id. at col. 4, lines 54-68 and col. 5, lines 1-2. The specification provides more references to the process's requirement that the number of sheets determines the timing of speed changes in the conveyors.

Fosber argues that this interpretation of "group" causes claim 9 to read on the Vermes prior art patent, U.S. Patent No. 4,040,618. Vermes, however, lacks at least two limitations of claim 9. In Vermes, the first conveyor is slowed in response to activation of an interrupt mechanism, not in response to passage of the last sheet of a group past the end of the first conveyor. See Vermes '618 patent, col. 9, lines 16-28. Indeed, the record shows that in reexamination, it was this limitation that the examiner relied on in allowing claim 9 over Vermes. Moreover, in Vermes, the second conveyor comes to a complete stop. See id. at col. 9, line 41. Assuming, without deciding, that a complete stop may indeed qualify as "slowing," in Vermes such a stop does not "thereby slow sheets traveling upstream of said group of sheets." This limitation in paragraph (c) requires that the slowing of the second conveyor play some part in causing upstream sheets to slow down. Instead, in Vermes, the interrupt mechanism is the only reason that sheets traveling upstream slow down. See id. at col. 9, lines 21-23. By the time the Vermes interrupt mechanism has released the upstream sheets, the second conveyor has resumed its normal speed. See id. at col. 9, lines 52-53.

Accordingly, to ensure that the preferred embodiment falls within the scope of the claim, this court interprets the term "group" as stated above. Beyond this alteration in the meaning of the term "group," this court affirms the district court's interpretation of other terms.
similar natural plant and mineral materials."

D. Term 7: "to provide maximum tractive effort . . ."

The Court construes the term "to provide a maximum tractive effort on the rear wheel for a given pressurized fluid flow regardless of wheel slippage conditions on the front wheels" in claim 1 of the '325 patent -- as well as the similar language in claims 9, 15, and 24 of the '325 patent and claims 1 and 9 of the '664 patent -- as follows: 3

A wheel -- call it Wheel A -- receives the "maximum tractive effort for a given pressurized fluid flow regardless of wheel slippage conditions" on other wheels if the pressurized fluid flow to Wheel A's motor is not affected by whether those other wheels slip.

This is essentially the construction proposed by Toro, Toro Opening Br. at 30, and it is consistent with the intrinsic evidence.

--- Footnotes ---

3 Claim 9 of the '325 patent refers to tractive effort on "each rear wheel" rather than "the rear wheel" (as in Claim 1), because claim 9 describes a device that may have multiple rear wheels. Claims 15 and 24 of the '325 patent and claims 1 and 9 of the '664 patent refer not to "front" and "rear" wheels, but rather to wheels on a "first end" and a "second end." These differences are inessential for claim-construction purposes.

--- End Footnotes ---

Textron would construe this limitation to require that "maximum tractive effort is always provided" to a particular wheel. Textron Opening Br. at 27 (emphasis added). 4 This construction would unduly limit the claim language and is unsupported by the intrinsic evidence. It is plain that maximum tractive effort need not "always" be provided to the rear (or other in-series) wheel. The motor might, for instance, be disengaged from the wheel (and thus providing less than the maximum tractive effort) while the vehicle is idling.

--- Footnotes ---

4 Toro makes much of the fact that Textron's proposed construction refers to a "rear wheel" even though some patent claims including the disputed language refer to wheels at a "second end" of the vehicle. Toro Opening Br. at 31. But Toro's proposed construction suffers the same flaw, as it refers to "the rear drive wheel." Id. at 30. The Court recognizes that both Toro and Textron used the adjective "rear" as shorthand, and nothing in this order turns on the parties' uses of the word "rear" in their proposed claim constructions.

--- End Footnotes ---

The key feature of the claimed invention captured by this limitation is not that maximum tractive effort -- which both Toro and Textron (and thus the Court) treat as being equivalent to the amount and force of the pressurized fluid flow -- is "always" applied to an in-series wheel. Rather, the key feature is that the tractive effort on the in-series wheel does not vary when one of the parallel-connected wheels slips. This contrasts with an all-parallel-drive system, in which slippage of one wheel affects the fluid flow to other wheels connected in parallel to the slipping wheel. The construction advocated by Toro and essentially adopted by the Court is consistent with the key innovative feature reflected in the patent claims.
TPI and HISI also disagree about the meaning of the phrase "passing the produced smoke through a filter to remove mainly the tar therefrom." TPI contends that this phrase should be construed to include any amount of filtering, "so long as some tar is removed." (TPI Brief 41.) More specifically, it argues that the language of this claim is broad enough to cover even filtering processes that render the smoke tasteless, such as the process described by the Kowalski Patent.

HISI, on the other hand, contends that this phrase protects only processes designed to remove the larger particles from the smoke, such as tar. It argues that the Yamaoka Patent does not claim a filtration process which removes the smaller flavor-giving particles from the smoke in addition to the larger tar particles. To the contrary, HISI argues, the Yamaoka Patent claims a process which imparts some flavoring to the fish that is not originally present in the fish. This flavoring can only be imparted, it argues, by allowing some of the smaller particles to pass through the filter.

The Court agrees with HISI that the language of the claim itself indicates that the Yamaoka process is designed specifically to remove tar from the smoke. This smoke is not passed through a filter, which happens to have the incidental effect of removing the tar, but is instead to be "passed through a filter to remove" the tar -- i.e., for the specific purpose of removing the tar from the smoke. The language of the claim does not appear to encompass a process that is intended to remove not only the tar, but also the smaller flavor-giving particles. Some ambiguity remains, however, because of the word "mainly." Therefore, the Court once again turns to the specifications of the Yamaoka Patent for additional guidance.

Here, the specifications confirm that the Yamaoka Patent does not claim filtration processes designed to remove other substances from the smoke in addition to the tar. The Yamaoka Patent initially summarizes the invention as follows:

"With a major part of the tar thus filtered off, the remaining smoke exerts preservative, sterilizing and color-keeping actions on substantially fresh fish and meat without imparting any disagreeable odor, taste or color thereto. Instead, the smoke imparts agreeable taste and smell to the processed fish and meat while keeping them in a substantially fresh condition."

(Yamaoka Patent, Col 3, at 20-26 ("emphasis added").) This language shows that not only does the Yamaoka Patent contemplate preserving fish without imparting disagreeable taste, but it also includes the addition of some type of taste or smell not naturally present in the fish. This taste and smell can only be imparted through particles not filtered out during the filtration process. While TPI is correct that the Yamaoka Patent's specifications discuss ways in which "[t]he level of aromatic smell characteristics of smoked products can be easily raised [(and presumably also lowered)] by varying the kind and quantity of the filtering materials," (Yamaoka Patent, Col. 7, at 4-6), the Yamaoka specifications always assume that some level of taste or aroma will be present at the end of the filtering process.

Accordingly, the Court determines the Yamaoka Patent claims a process for filtering smoke to the extent that the smoke produced by the filtration is still able to impart a noticeable and "agreeable" taste and smell to the fish. The Yamaoka Patent does not claim a process specifically intended to filter flavor-giving particles out of the smoke.

4181

i. "To the Atria"

Medtronic asserts that the cardioverting energy must be substantially confined to the atria, and that any cardioverting energy passing through the ventricles must be minimized or reduced. Guidant asserts that cardioverting energy may pass through the ventricles and other anatomy when applying cardioverting energy to the atria without departing from the claim.

Medtronic focuses its argument on how the cardioverting energy is applied to the atria, contending that the patent revolves around a "unique shocking vector." It argues that "to the atria" means that cardioverting energy is applied directly to the atria, rather than traveling through other tissue before reaching the atria. (Medtronic asserts that the ordinary meaning of "to the atria" might result in an absurd meaning, so it argues that the energy must be "substantially" confined to the atria.)

Medtronic asserts that because the 219 Patent, and all of the patents in the case, describe devices that do not have the ability to detect or shock the ventricles, the focus of the inventions is the prevention of ventricular fibrillation. Medtronic argues that the patents demonstrate that ventricular fibrillation is avoided by reducing "the amount of the electrical energy which is
passed through the ventricles during cardioversion of the atria," and by placing electrodes so that the electrical shock is substantially confined to the atria. '219 Patent at 2:22-32, 5:12-19; '836 Patent at 2:23-34, 5:50-57; '600 Patent at 2:25-36, 5:45-52.

Guidant focuses on the term "to apply" found in the claim to support is argument regarding the term "to." The element describes a "cardioverting means for applying said cardioverting electrical energy to the atria." It argues that the ordinary meaning of the term "to apply" means "to bring into action." Webster's Ninth New Collegiate Dictionary 97 (1990). It asserts that "to" is "used as a function word to indicate movement or an action or condition suggestive of movement toward a place, person, or thing reached." Id. at 1238. Thus, Guidant contends that a correct interpretation requires that the cardioverting energy is brought into action and directed toward the atria.

Guidant emphasizes that the element uses the term "when" and notes that the U.S. Patent Office recognized that the "when" clause is the principal contribution of the inventions claimed in the '219 Patent. The Patent Office found, "There is no teaching in the prior art of record for supplying cardioverting means which, when necessary, cardiovert the atria when the time between immediately successive ventricular activations is greater than a preselected minimum time interval." Notice of Allowability, at 2, Guidant Exh. 49.

Guidant also notes that the '219 Patent uses the term "applying cardioverting electrical energy to the atria" when describing an alternative embodiment: the use of an invention with an external electrode system that passes as much energy through the ventricles as it does through the atria. '219 Patent at 8:35-43. During transthoracic defibrillation in humans, only four percent of the transthoracic current actually transverses the heart. See Bruce B. Lerman & O. Carlton Deale, Relation Between Transcardiac and Transthoracic Current During Defibrillation in Humans, 67(6) Circulation Research 1420 (Dec. 1990). Thus, Medtronic's interpretation of the element is inconsistent with the specification.

The Court first examines the explicitly recited function, and then searches for the structure in the specification that is necessary to perform that function. Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1330 (Fed. Cir. 2003). As a starting point, the Court must determine the ordinary meaning of the claim terms. Medtronic does not provide the Court with definitions for the words "apply" and "to." However, the Court determines that Guidant's proffered dictionary provides a definition for the word "to" that seems in concert with Medtronic's interpretation of that word.

Guidant focuses on the term "to apply" found in the claim to support is argument regarding the term "to." The element describes a "cardioverting means for applying said cardioverting electrical energy to the atria." It argues that the ordinary meaning of the term "to apply" means "to bring into action." Webster's Ninth New Collegiate Dictionary 97 (1990). It asserts that "to" is "used as a function word to indicate movement or an action or condition suggestive of movement toward a place, person, or thing reached." Id. at 1238. Thus, Guidant contends that a correct interpretation requires that the cardioverting energy is brought into action and directed toward the atria.

Guidant emphasizes that the element uses the term "when" and notes that the U.S. Patent Office recognized that the "when" clause is the principal contribution of the inventions claimed in the '219 Patent. The Patent Office found, "There is no teaching in the prior art of record for supplying cardioverting means which, when necessary, cardiovert the atria when the time between immediately successive ventricular activations is greater than a preselected minimum time interval." Notice of Allowability, at 2, Guidant Exh. 49.

Guidant also notes that the '219 Patent uses the term "applying cardioverting electrical energy to the atria" when describing an alternative embodiment: the use of an invention with an external electrode system that passes as much energy through the ventricles as it does through the atria. '219 Patent at 8:35-43. During transthoracic defibrillation in humans, only four percent of the transthoracic current actually transverses the heart. See Bruce B. Lerman & O. Carlton Deale, Relation Between Transcardiac and Transthoracic Current During Defibrillation in Humans, 67(6) Circulation Research 1420 (Dec. 1990). Thus, Medtronic's interpretation of the element is inconsistent with the specification.

The Court first examines the explicitly recited function, and then searches for the structure in the specification that is necessary to perform that function. Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1330 (Fed. Cir. 2003). As a starting point, the Court must determine the ordinary meaning of the claim terms. Medtronic does not provide the Court with definitions for the words "apply" and "to." However, the Court determines that Guidant's proffered dictionary provides a definition for the word "to" that seems in concert with Medtronic's interpretation of that word.

The Court can find nothing in the specification or claim language that counsels against adopting the ordinary meaning of the word "applying." In this case, the Court finds that the definition which best fits the claim is "to bring into action."

The Court agrees with Guidant that the definition of "applying . . . cardioverting energy to the atria" means that energy is directed toward the atria. Medtronic improperly imports limitations from the preferred embodiment to come to its conclusion that cardioverting energy must go only to the atria. The claim does not include any language which limits the application of energy only to energy applied directly to the atria. Moreover, the claim also does not say that energy is to be applied only to the atria, or that energy must not be applied to the ventricles. The fact that the preferred embodiment places the electrodes in such a way so as to limit the flow of electricity to the ventricles is not dispositive. This invention teaches technology having the unique feature of timing the cardioversion. See '219 Patent at 2:66-3:4 (stating that the invention reduces the risk of inducing ventricular fibrillation by "interval timing prior to applying the cardioverting or defibrillating electrical energy"). Moreover, it is improper to limit claim construction based on the "perceived 'purpose" of the invention. Rather, the Court should interpret claims according to their plain language unless the patentee has chosen to be his own lexicographer in the specification or has clearly disclaimed coverage during prosecution." E-Pass Techs., Inc. v. 3COM Corp., 343 F.3d 1364, 1370 (Fed. Cir. 2003).

While the preferred embodiment states that the electrodes are placed so as to "substantially confine" the cardioverting energy to the atria, that placement is not what is explicitly claimed in the claim language. To require such a limitation would be to improperly import limitations that are not in the claim. See Tehrani v. Hamilton Med., Inc., 331 F.3d 1355, 1362-63 (Fed. Cir. 2003) (holding that the lower court improperly imported a limitation from the specification when it interpreted a claim to describe "automatic measuring" when the claim only stated "measuring").

The Court notes that its finding is consistent with Federal Circuit precedent. In interpreting a patent in which liquid had to flow "to" the second pumping means, the Federal Circuit held that "the 'to' limitation requires only that the liquid move from the filter 'in a pathway with a destination of the second pumping means' and does not preclude the fluid from passing
The file history thus reveals that, in order to obtain the patent, the claim language was modified to require the chimney to "

words "to the hole" were added to the claim in order to assuage the examiner's continuing concerns. Finally, after all of

the concessions had been made, the PTO issued the '996 patent. 

If there was any doubt that this construction was the correct one, it is dispelled by a review of the file history for the '996 patent. The file history reveals that the inventor had to endure several rejections from the Patent and Trademark Office (PTO) before the '996 patent was finally issued. These initial rejections were based on the PTO examiner's failure to understand how the invention worked; for example, he stated that it was "unclear how the air can leave [the opening] as it 

through intervening components." Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1458-59 (Fed. Cir. 1998). Thus, "to the atria" means that the electric shock must be directed toward the destination of the atria, but that the electric shock may pass through the ventricles on its way toward the atria.

The next claim construction issue, one that all the parties weigh in on, deals with how the word "to" is to be construed in the claim element "to the opening in said sleeve." Brita contends that this claim language merely requires that the chimney portion of the air collecting space extend in a direction towards, but not necessarily reach the elevation of, the opening in the sleeve. The Defendants, on the other hand, assert that the direction "to" requires that the chimney terminate at or above the sleeve hole. Not only do the Defendants rely on the plain meaning of the word "to," but they also argue that the file history makes clear that the inventor intended the air collecting space to reach the hole.

It is first important to look at the disputed claim language in the context in which it was used. The entire clause reads: "... said means defining the air collecting space extending upwardly at least partially towards the side wall and to the opening in said sleeve..." First off, Brita asserts that the adverb "partially" modifies not only "towards the side wall" but also "to the opening in said sleeve." Under this reading of the claim, the air collecting space would only need to extend partially toward the sleeve opening but not necessarily all the way to the opening.

The Court finds Brita's first argument wholly without merit. Not even under the most tortured reading of this claim could the Court agree that the word "partially" was intended to modify 'to the opening.' The only reasonable construction of this clause finds that "partially towards" describes how the air collecting space extends in the direction of the side wall, while "to" specifies the chimney location in relation to the sleeve opening. If the inventor wanted to have the chimney only extend "partially" in the direction of the opening, he could have either (1) inserted the word "partially" before "to", or (2) eliminated the word "to" entirely. The claim was not written in this way, however, and thus the Court refuses to read "partially" as modifying "to the opening."

The Court also does not buy Brita's argument that "to" should construed as meaning "towards." The inventor knew how to use the word "towards" - in fact, he did so five words earlier in describing the air collecting space's position relative to the side wall. Instead of again using the word "towards" in describing its direction relative the sleeve opening, however, the inventor chose to have the claim require that the chimney extend "to" the opening. When two different words are used in such close proximity to one another, the Court believes that they were intended to have different meanings. See, e.g., Hoffman v. Joint Council of Teamsters No. 38, 230 F. Supp. 684, 690 (N.D. Cal. 1962). When read in context, therefore, the word "to" clearly requires the air collecting space to reach all the way to the hole in the sleeve. Other definitions of the word "to" may be reasonable in other contexts, see Cybor Corp. v. FAS Technologies, Inc., 138 F.3d 1448, 1459 (Fed. Cir. 1998) (noting that "to" can be can be construed to mean "in a direction toward"). Thus, the Court finds that the chimney portion of the air collecting space must reach the elevation of the sleeve opening, and not merely extend in a direction toward the opening.

The file history thus reveals that, in order to obtain the patent, the claim language was modified to require the chimney to...
extend to the elevation of the opening. It is a basic tenet of patent law that a patent holder cannot seek claim coverage for that which he has conceded during the prosecution of the patent. Vitronics, 90 F.3d at 1583. When the examiner raised his initial objections, the inventor could have corrected the drawing to show that air could still escape even if the chimney did not reach the hole. But, instead of choosing this path, the inventor modified both the patent drawings and the claim language to reflect a chimney portion which did reach all the way to the sleeve opening. In doing so, this requirement became part of the patent, and the Court will not allow Brita to now reclaim this prior concession. Thus, the file history illustrates, with crystal clarity, that the chimney portion of the air collecting space was intended to, and therefore must for claim construction purposes, extend to the elevation of the sleeve opening.

3. "to the opening in said sleeve"

Finally, Brita contends that the district court erred in interpreting "to the opening in said sleeve" as requiring the air collecting space to physically reach the same height as the opening in the sleeve. According to Brita, as long as there is a continuous air path from the bottom of the filter to the opening in the side of the sleeve, the "to the opening" limitation is satisfied. Brita is incorrect.

As described above, the air collecting space is defined in the claim as "extending upwardly at least partially towards the side wall, and to the opening in said sleeve." The plain meaning of "to the opening" requires the air collecting space to reach the physical height of the sleeve opening. This does not allow, as Brita contends, an arrangement where the air collecting space merely extends partially toward the opening, with "ambient" air extending the rest of the way. This point is illustrated by the juxtaposition of the "at least partially towards" language regarding the side wall and the use of "to" regarding the opening. Brita clearly understood a difference between "at least partially towards" and "to" when claiming the extent of the air collecting space in relation to other aspects of the insert. Brita cannot now rewrite the claim to read "at least partially towards" the opening in the sleeve. We must give effect to the claim as written, not as Brita wishes it had been written.

1 To the extent this argument implies that the "air collecting space" is all space between the insert and the sleeve, it was dealt with in section A.1, supra.

Further, the district court's understanding of the claim language is supported by the prosecution history. As originally filed, claim 1 of the '996 patent did not contain the limitation that the air collecting space extend "to the opening" in the sleeve. Because the path of the air flow was not defined, the Examiner did not understand how the invention worked and rejected the claim. In response, Brita argued that Figure 4 of the '996 patent clearly showed that the air collecting space terminated above the opening in the sleeve. In addition, Brita amended claim 1 to contain the "to the opening in said sleeve" limitation. By stressing to the Examiner that the claimed air collecting space must extend to the level of the opening, Brita has locked itself in to this claim construction. See Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1677 (Fed. Cir. 1995) ("Claims may not be construed in one way to obtain their allowance and in a different way against accused infringers."). Thus, in order to infringe claim 1, the air collecting space of an accused device must physically extend to the opening in the sleeve.
excluding the embodiments of figures 3-15 from the scope of the claim. PC Guardian responds that the district court adopted the ordinary meaning of this clause, as was argued by Kensington during the claim construction hearing. PC Guardian also states that the district court correctly construed the claim to require that rotation of the slot engagement member "to said unlocked position" must be inhibited by extension of the pin.

We confirm the district court's construction of this clause. The specification shows that the pin extends through the security slot to prevent rotation of the slot engagement member into the unlocked position and removal from the slot. In the embodiments of Figures 3-15, the pin inhibits rotation of the slot engagement member to the unlocked position by extending through the security slot and maintaining the position of the lock housing in relation to the slot and the slot engagement member. Those embodiments, therefore, are consistent with the prosecution record, and are not excluded from the scope of this element as correctly construed. We conclude that the claim requires a pin that can be extended into the security slot and thereby inhibit rotation of the slot engagement member between the locked and unlocked positions.

Lastly, the parties dispute the proper construction of the term to convert said beam to a line of light on surfaces to which it is projected. According to Irwin, this term means that the laser must form a line on a remote surface to which the beam is projected. Orosz claims that the term only requires a line be projected on a surface.

Irwin first claims that the dictionary definition for the terms "to which" is suggestive of movement toward a place, person, or thing. The term "to," though, is a prepositional phrase that has multiple interpretations. Moreover, the dictionary definition proposed by Irwin is still broad enough to encompass projection on any surface -- even a surface the device sits upon -- and not just a remote surface.

Irwin next argues that the specification repeatedly states that the laser aligns spaced points in space which are projected to a surface. Irwin further contends that the figures with the patent specification show the beam projected between two points on a remote surface. However, lines 47-55 of column 2 in the patent specification state that a line may be projected on a reflective surface, not a remote surface. Furthermore, this specification reference also indicates that a line could be projected at any desired angle. Thus, the patent specification fails to consistently limit this disputed term to only permitting a line projected on a remote surface.

Irwin asserts that the prosecution history supports its construction. According to Irwin, the patented device was distinguished over the prior art because the patented device projects a line through space. In contrast, the prior art formed a line that would act as a guide for a cutting tool on the surface the device embodied in the prior art was mounted. However, the '081 patent was not distinguished over the relevant prior art (Jehn) on the basis of what surface the line was projected. Instead, the '081 patent distinguished the prior art by combining a portable laser unit, which uses a line-forming lens instead of a diffuser, with a level. Furthermore, the prosecution history also confirms "that a line of light can be projected on a surface from which it is reflected at a desired angle relative to horizontal;" this description could also include zero degrees, which would project the line of light onto the surface the device was mounted. (Pl.'s App. at A0067).

Lastly, Irwin contends that the intended use of the patent, for medical applications, supports its construction. Although it is appropriate to consider the intended use of the invention in construing the claims, the problem the inventor was attempting to solve is only "a relevant consideration," not a determinative one. CVI/Beta Ventures v. Tura LP, 112 F.3d 1146, 1160 (Fed. Cir. 1997). Here, while Orosz intended the invention to be used primarily for medical purposes, the specification reveals that the invention could be used for construction and engineering purposes as well.

In light of the above analysis, the disputed term does not require that the line be projected onto a remote surface, as stressed by Irwin. Rather, the ordinary meaning of the term only requires that the device project the beam as a line on a surface, regardless of whether the surface is a remote surface.

CONCLUSION

For the foregoing reasons, the disputed terms of the '081 patent are construed, consistent with this opinion, as follows: (1) a pen-light laser is a laser that is about as small and slender as a fountain pen, and the pen-light laser may be part of a larger,
portable laser unit; (2) leveling means directly associated therewith only requires that the leveling means have a fixed relationship with the pen-light laser; (3) a transparent bar is a transparent and straight, cylindrical, rod-like piece that is considerably longer than it is wide; and (4) to convert said beam to a line of light on surfaces to which it is projected only requires that the device project the beam as a line on a surface, regardless of whether the surface is a remote surface.

**I. Developer**

The claim term "developer" is a term of art in the xerographic industry. Ricoh argues that developer is "charged particles for developing a latent image," and that the terms "developer" and "toner" are used interchangeably. JCCS at 7. Defendants argue that developer is a mixture of toner and carrier, and that the two terms "developer" and "toner" have distinct meanings and are used selectively throughout the patents. The Court places a heavy presumption in favor of the ordinary meaning of claim language as understood by one of ordinary skill in the art. See Johnson Worldwide, 175 F.3d at 989. However, this presumed ordinary and accustomed meaning may be overcome where the patentee has chosen to become his own lexicographer. See id. at 990. When a patentee has become his own lexicographer the term may be expressly or implicitly defined, and the specification is dispositive in defining the disputed term. "In other words, the specification may define claim terms 'by implication' such that the meaning may be 'found in or ascertained by a reading of the patent document.'" Bell Atl. Network Servs., Inc. v. Covad Commun's. Group, Inc., 262 F.3d 1258 (Fed.Cir. 2001)(citing Vitronics, 90 F.3d at 1582). Although, "there is presumed to be a difference in meaning and scope when different words or phrases are used in the separate claims," here the Court finds that the inventor clearly equates the terms "developer" and "toner" throughout the patent specification and prosecution history. United States v. Telectronics, 857 F.2d 778, 783-84 (Fed.Cir. 1988). The specification of the '662 patent states "the bottle holder 21 plays the role of holding means for holding a toner bottle, or developer container 20." '662 patent, Col 6 ll. 30-31. The specification also consistently describes the bottle as holding toner, for example, "as shown, the amount of toner left in the bottle 20 depends on the rotation speed. '662 patent, Col. 19 ll.13-15. In the summary of the preferred embodiments, the container is once again referred to as a "developer container." See '662 patent, Col. 24 ll 20- 68. This Court finds that throughout the specification patents at issue, the terms "toner" and "developer" are used synonymously and interchangeably, and mean "charged particles for developing a latent image." JCCS at 7.

**2. Tongue**

The second term to be interpreted is "tongue" in the '486 patent, independent claims 1 and 65, and dependent claims 5, 10, 38 through 39, 42, 50, 53 (which depend on claim 1); and in the '836 patent, independent claims 1 through 3, claim 10, claim 23, and claims 26 and 27, and dependent claims 4 through 7, 11 and 12.

Unilin proposes that "tongue" be construed as "a protrusion extending distally from a side spaced inwardly from the top and bottom surfaces and including at least one locking element." (Unilin's Open. Br. 13.) Alloc initially proposed the construction "that portion of the male side of the panel that projects out beyond the top edge thereof, and the lower side thereof is the underside of the portion." (Jt. Claim Constr. Charts, '486 chart 1.) But, Alloc's subsequent submissions disclose that it apparently abandoned its initial proposed construction 3 and that, with the exception of the final clause "and including at least one locking element," Alloc joins in Unilin's proposed construction. (See Alloc's Resp. Mem. 14.)

--- Footnotes ---

3 To the extent such construction is not abandoned, Alloc's construction limits the tongue to that part of the side edge "that projects out beyond the top edge." Such construction would exclude the locking element 33 from being part of the tongue which is inconsistent with both the claim language and the specification. (See '486 patent Fig 22.) Therefore, Alloc's initial construction of tongue is rejected.
A representative use of "tongue" appears in claim 1 of the '836 patent as follows: "said coupling parts comprising substantially a tongue and a groove extending along panel side edges generally parallel to the panel underside and including integrated mechanical locking elements, said tongue, groove and locking elements formed in one piece with the panel, said tongue, groove and locking elements arranged to prevent drifting apart of the floor panel." ('836 patent, 13:64-67; 4:1-4) (emphasis added.)

The context of the surrounding words of the claim must be considered in determining the ordinary and customary meaning of those terms. ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1088 (Fed. Cir. 2003). Unilin's construction of "tongue" as "including at least one locking element," does not fit when considered in the context of the claims. For example, claim 1 of the '836 patent, in which "tongue" appears, also includes the phrase "locking elements" three times. Similarly, claim 65 of the '486 patent, in which "tongue" appears, also includes "locking element" twice and "locking elements" twice.

The flaw in Unilin's proposed definition is highlighted by consideration of a portion of claim 65 which reads: "said locking elements comprising a locking element in the form of a downwardly extending protrusion located on the lower side of the tongue and an upwardly facing cooperating locking recess in the lower lip." ('486 patent, 20:4-7.) If Unilin's proposed definition of "tongue" is inserted in place of the word "tongue," as indicated by the bold italic type, the claim would read:

said locking elements comprising a locking element in the form of a downwardly extending protrusion located on the lower side of a protrusion extending distally from a side spaced inwardly from the top and bottom surfaces and including at least one locking element and an upwardly facing cooperating locking recess in the lower lip.

The inclusion of "at least one locking element" in the definition of "tongue" results in a duplicity of "locking element" and renders the term "tongue" nonsensical in the context of the claims. Therefore, the Court defines "tongue" as "a protrusion extending distally from a side spaced inwardly from the top and bottom surfaces."

3. Tongue section

Claims 5 and 10 use the phrase "tongue section." Figure 3A shows teardrop shaped tongue 206, which connects both to brace 214 and carriage unit housing 142. Defendants argue that "tongue section" in claims 5 and 10 must be construed as referring only to a projecting member that resembles or suggests a human tongue by its shape or position. I find this argument unpersuasive. There is no expressed intention by the patentee to narrowly define this element in this way. In fact, "unless compelled to do otherwise, a court will give a claim term the full range of its ordinary meaning as understood by an artisan of ordinary skill." Rexnord, 274 F.3d at 1342. A tongue is a projecting strip that may, but need not, resemble or suggest a human tongue. See 2 The World Book Dictionary 2204 (1990) ("tongue" defined in machinery context as "a projecting flange, rib, or strip for any purpose"). The phrase tongue-and-groove is a good example of a projecting strip that traverses the entire edge of a board that does not resemble the human tongue in shape. Moreover, adopting defendants' construction of "tongue section" would unnecessarily exclude the preferred embodiment, which is a teardrop shaped tongue. See Vitronics, 90 F.3d at 1583 (claim interpretation that excludes preferred embodiment "is rarely, if ever, correct").

3. The Meaning of "Tool"

The central dispute in this case is whether the scope of the '801 patent includes, from the patent specification, a limitation based upon the tie-insertion tool. For the sake of perspective, I note that this matter will be important when we consider whether the '93 Brochure "anticipated" the '801 patented method (i.e. whether the '93 Brochure would have enabled a person of ordinary skill in the art to figure out and practice Helifix's patented method). Helifix's assertion is that the '93 Brochure cannot have enabled a person to have practiced the method because the brochure did not tell the reader how to build the tool.
that would allow him or her to have practiced the method. Blok-Lok argues that the patent is not limited by the tool. That is, because the '801 patent does not have to be practiced by any particular type of tool, the failure of the '93 Brochure to teach how to build the Helifix insertion tool does not preclude that brochure from anticipating the patent.

The '801 patent specification explains and portrays the tool that Helifix had created to practice the patented method. The specification states, "It is necessary to appreciate that the power source is a hammer drilling machine fitted with an SDS chuck." (Plaint. Ex. 1, col. 5, lines 44-5). This language is as close as the patent comes to defining "tool" in a manner different from the ordinary usage of the word.

I conclude that Helifix is not correct in arguing that the patent could only be practiced with the tool described and illustrated in the patent specification. In rejecting the '465 Application -- in which Helifix was attempting to patent in a single patent the tie-insertion tool and the method that ultimately was patented in Claim One (Def. Ex. 557) -- the PTO Examiner wrote that the method was "distinct" from the tool because "the adapter is not required to insert the tie." (Def. Ex. 557, "Restriction/Election" document, p. 2-3). Accepting that determination, I conclude that the "tool" referred to in Claim One is not limited by the statements made about Helifix's tool in the patent specification.

--- Footnotes ---

8 A patent claim is typically drafted in three parts: the preamble, the transition; and the body. 3-8 Chisum on Patents § 806[1][b] (2007). In the '787 patent, as in many patents, the preamble consists of the language preceding the transition phrase "comprising." See, e.g., Bicon, Inc. v. The Straumann Co., 441 F.3d 945, 949 (Fed. Cir. 2006).

Therefore, preamble language does not limit the scope of a claim when it merely states a "purpose or intended use of the invention." In re Paulsen, 30 F.3d at 1479. However, "when the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects." Bell Comm'n Research, 55 F.3d at 620.
Perouse argues that this entire phrase should be disregarded because it "is a claim preamble which merely states an intended use of the invention and does not limit the claim." (Perouse Opening Br. 16.) Gore concedes that "for fitting a self-expanding stent" is a non-limiting statement of intended use, but maintains that "tool" is a substantive limitation requiring construction. (Gore Reply Br. 3.) The Court agrees that "for fitting a self-expanding stent" describes an intended use of the claimed apparatus, and will not construe this portion of the preamble. See Catalina Mktg. Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 809 (Fed. Cir. 2002) ("Preambles describing the use of an invention generally do not limit the claims because the patentability of apparatus or composition claims depends on the claimed structure, not on the use or purpose of that structure.").

With respect to "tool," however, the Court finds that this is a substantive limitation requiring construction. The body of claim 1 merely recites three elements. Standing alone, the body does not "fully . . . set[] forth the complete invention" of the '787 patent because the invention is not a set of three unassembled constituents, but a tool that includes these three elements and that can be used to implant a self-expanding stent within the body. (See '787 patent col.2 11.46-47 ("Another aspect of the invention is a tool for lifting an auto-expansible endoprosthesis . . . ").) Pitney Bowes, 182 F.3d at 1305. In the context of claim 1, "tool" is clearly necessary for "life, meaning, and vitality," and will be construed as a substantive limitation. Id.

Gore argues that "tool" should be construed to mean "a single instrument having the three constituents recited in the body of the claim (a guide tube, a housing part, and a housing part opener), none of which may be a part of the object to be fitted." (Gore Proposed Order.) Perouse contends that, if the Court should find that the term "tool" requires construction, the proper construction is "instrument." (Perouse Opening Br. 17.)

With respect to Gore's proposed limitation, "having the three constituents recited in the body of the claim (a guide tube, a housing part, and a housing part opener)," Perouse argues that this construction is redundant, unnecessary, and confusing. (Perouse Reply Br. 10.) The Court agrees. The body of claim 1 already includes the "guide tube," "housing part," and "housing part opener" limitations. It would add nothing to the construction of the claim to read these limitations into the preamble word "tool" as well. Even if it were not redundant, Gore's proposed limitation would be rejected as improper claim construction. None of these three constituents are part of the ordinary meaning of "tool," and their inclusion would improperly import limitations from the specification into the claims. See Phillips, 415 F.3d at 1323-24.

Gore's proposed construction includes a further limitation--that "none of [the guide tube, housing part, and housing part opener] may be a part of the object to be fitted." In other words, Gore's proposed construction of "tool" requires that the "tool" and the "object to be fitted," i.e., the stent, are physically distinct, separate structures. (See Gore Opening Br. 21-25.)

Gore argues that the stated purpose of the tool, "for fitting a self-expanding stent," implies that the tool and the stent must be physically separate structures. (Gore Opening Br. 21.) Gore further notes that the drawings in the '787 patent depict the endoprosthesis and tool as separate objects, and that the specification describes an endoprosthesis that is "inserted" into the tool. (Gore Opening Br. 22.) However, while it is true that the specification and drawings describe a tool that is physically separate from the object to be fitted, it is improper claim construction to import limitations from the specification to the claims unless there is a clear disclaimer of claim scope. See, e.g., Gillette Co. v. Energizer Holdings, Inc., 405 F.3d 1367, 1374 (Fed. Cir. 2005) ("This court declines to import limitations to the claims from the specification absent a "manifest" or "explicit" exclusion."); Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) ("Even when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using 'words or expressions of manifest exclusion or restriction.'"). There is no disclaimer, clear or otherwise, of "tools" that incorporate the object to be fitted, and therefore no justification for this Court to deviate from the ordinary meaning of the term "tool."

Gore also argues that its proposed limitation is appropriate in light of the prosecution history of the '787 patent, in which a restriction requirement was issued against the '137 application (the parent application to the '787 patent) and the applicants responded by electing to pursue the "tool" and "stent" claims in separate applications. Gore apparently contends that the restriction requirement and the applicant's election in compliance with this requirement somehow invoked a limitation of physical separateness between the tool and stent upon the patent claims that issued following this election. Gore has cited no case law, and the Court is aware of none, that suggests that a restriction requirement limits the construction of claims in a later filed divisional application in the manner suggested by Gore. (See Gore Opening Br. 24-25; Gore Reply Br. 6.) Most courts that have considered similar issues have noted that a restriction requirement is primarily an administrative tool. See, e.g., Amersham Pharmacia Biotech, Inc. v. Perkin-Elmer Corp., 2000 WL 34204509, at * 16 (N.D. Cal. Feb. 28, 2000)
The Court construes "a tool for fitting a self-expanding stent" to mean "an instrument."
The parties do not dispute that a "tooth" is the cutting surface of a blade. (Pl.'s Opp'n to Mot. for Summ. J. 22; Def.'s Mot. for Summ. J. 14.) Some claims of the patents also describe the teeth as "shaped substantially as right triangles," but the court construes that term separately below. Defendant contends, however, that the specification indicates that all claims refer to teeth that are triangular because of three embodiments disclosed in the patents. (353 Patent, 3:1-2; 253 patent, 3:3-4.) Defendant similarly notes that both patents also describe, in their description of preferred embodiments, teeth as being "formed from two sides, which coalesce to form the tooth." (353 patent, 4:53-54; 253 patent, 4:55-56.)

The court cannot read a limitation into a claim from the embodiments in the specification. Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1988) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations" (citation omitted).) Therefore, the court concludes that it is sufficient to say that a "tooth" is a cutting surface.

4192

Powell argues that the Industriaplex device infringes each of the six claims of the '039 patent. Home Depot first responds that the Industriaplex device does not infringe any of the claims of the '039 patent because it does not include "a table having a top." The phrase is used in the preambles to claims 1 and 4 of the patent, and the bodies of claims 1 and 4 include the phrase "table top." Claims 2, 3, 5 and 6 are claims that expressly refer to and incorporate claims 1 and 4, but with further additions. Home Depot thus claims that because the Industriaplex device has no table top, the device does not infringe the '039 patent.

The claims of the '039 patent are in so-called Jepson form, which refers to a patent claim that describes an improvement or addition to a previously-known device or design. "Jepson form allows a patentee to use the preamble to recite elements or steps of the claimed invention which are conventional or known." Epcon Gas Systems, Inc. v. Bauer Compressors, Inc., 279 F.3d 1022, 1029 (Fed. Cir. 2002) (internal quotations omitted). When a patentee has chosen to employ the Jepson form, the choice suggests that the patentee intends to use the preamble to define the elements of the claimed invention. Thus, the preamble is a limitation in a Jepson type-claim. Id.; Kegel Co. v. AMF Bowling, Inc., 127 F.3d 1420, 1426 (Fed. Cir. 1997).

The preamble to claims 1 and 4 describe the claimed invention as intended for use "in combination with a radial arm saw assembly comprising a table having a top . . . ." '039 patent 7:8-9, 8:1-2. The body of claim 1 goes on to describe the safety device as comprising in part "a work surface mounted to the table top." Id. 7:17. The body of claim 4 similarly describes the invention as comprising in part "a planar top work surface mounted on the table top." Id. 8:9. The Industriaplex device requires that the radial arm saw's table top be removed prior to installation. Defs.' Statement of Facts P 36-38. Powell responds that "top" in this instance simply means a physical location -- i.e. the uppermost edge of the table -- and not a physical structure or object. Thus, according to Powell, the Industriaplex device contains this limitation because, like Powell's Safe Hands device, it is attached to the top of the table, notwithstanding that the table top is removed during installation.

Powell's argument must be rejected for several reasons. First, the phrase "table having a top," found in both preambles, strongly implies that the referenced "top" is a physical object or structure, not merely a particular point in space. Every object -- every table, for example -- has a "top" in the sense that, given the object's orientation and a fixed frame of reference, one point on the object is the uppermost or the highest. If this is what is meant by "top," then the words "having a top" are superfluous as used in the phrase "table having a top." This would violate the Federal Circuit's rule that a claim construction which renders some words meaningless is disfavored. See Stumbo v. Eastman Outdoors, Inc., 508 F.3d 1358, 1362 (Fed. Cir. 2007); Bicon, Inc. v. Straumann Co., 441 F.3d 945, 950 (Fed. Cir. 2006).

Second, the use of the word "top" in the claims suggests that it is a reference to a tangible object, rather than a location. For example, claim 1 refers to "a work surface mounted to the table top," and claim 4 refers to "a planar top work surface mounted on the table top . . . ." '039 patent 7:17, 8:9. The word "mount" is defined as to "place, fix, or fasten on or in the proper support, backing, etc. for the required purpose" -- the "support" or "backing" in this case being the table top. See Webster's New Universal Unabridged Dictionary (2d ed. 1983). Thus an object can be "mounted" only on another physical object, and not on a point in space. Similarly, both claims 1 and 4 describe a "cutting box defining an interior bounded by a top in spaced relation with said work surface, opposing side walls, and front and rear walls." '039 patent 7:22-24, 8:16-18. If
the "top" were merely a point in space, and not a physical object, it could not define an interior, as described in the claims.

Third, the claims themselves use different language when intending to refer to the top of the table as a location. Claims 1 and 4 both describe the cutting box as "disposed on top of the work surface." '039 patent 7:21, 8:15. Notably, these limitations were not phrased as the cutting box being "disposed on the work surface top." This suggests that the patentee (Powell) used different language when he meant to refer to "top" as a location, as opposed to "top" as a physical structure.

For these reasons, the court concludes that the Industriaplex device does include, and is not meant to be used in combination with, a table "top" as that word is used in the patent. This alone is fatal to Powell's literal infringement claim, because "[l]iteral infringement requires that each and every claim limitation be present in the accused product." Abraxis Bioscience, Inc. v. Mayne Pharma (USA) Inc., 467 F.3d 1370, 1378 (Fed. Cir. 2006). Nevertheless, the court proceeds to examine the remaining arguments regarding literal infringement.

The parties contest the scope of the word "top" and "skirt," which appear in claims 3 and 14. Phoenix argues that the top is the "upper portion that covers the container"; Silgan argues that it is "the upper central portion (convex as seen from the interior) of the cap which is bounded by the depending peripheral skirt and from which the sealing protrusions depend." In essence, Phoenix maintains that the top includes the curved outer edge of the upper portion of the cap, and ends somewhere near the point where the outer edge becomes vertical. Silgan maintains that the top ends where it transitions from convex to concave. As for the term "skirt," Phoenix defines it as "the outer portion," and Silgan defines it as "that portion of a cap which bounds the top of the cap and depends peripherally therefrom and which includes a generally cylindrical portion for engagement with the cylinder."

Both parties cite the specification to support their proposed definitions. At column 2, lines 17-18, the specification states, "The top . . . is generally convex as viewed from inside of the cap." Silgan says this passage suggests that the top ends near where it transitions from a convex to concave shape, 1 though we note that saying the top is generally convex does not mean that it is entirely convex. On the other hand, at column 3, lines 20-21, the patent describes the skirt as "generally the same diameter as the upper part of the base." This description suggests that the skirt ends near where the cap transitions from concave to being a more or less straight vertical line.

--- Footnotes ---

1 When we use the terms concave and convex, we mean as viewed from the interior of the container.

--- End Footnotes ---

If one examines these definitions of top and skirt collectively, one quickly realizes that the concave portion of the cap -- the curved portion or the outer edge -- remains unnamed. Silgan argues that the concave area is part of the skirt, because one of the preferred embodiments illustrates a number of "stops or projections on the interior surface of the skirt," some of which extend into the concave area. The Court rejects this argument. Though the specification requires stops or projections on the interior surface of the skirt, nothing in the specification limits the projections from extending into the top.

The only other meaningful description of the top or skirt that sheds light on whether the concave portion should be labeled the top, the skirt, or some combination of the two is, as Phoenix suggests, in the claims themselves, which say that the skirt "depends from the top." Silgan argues that the skirt can depend outwardly and downwardly from the top, so that it can include the concave portion of the top. This interpretation, however, is contrary to the ordinary meaning of the word "depend," which means to hang down, just as the annular protrusions described in the patent depend, or hang down, from the top. See Webster's Third New International Dictionary 604 (1993). Given this additional description, the Court concludes that the top includes the concave portion as well as the convex portion, so that the skirt -- consistent with the description in the claims -- depends from the top.
Thus, the court adopts the following construction: the top is the upper portion of the cap from which the sealing protrusions and skirt depend, and the skirt is the outer portion of the cap which is generally the same diameter as the upper portion of the base.

1. The '181 Patent

The '181 patent is titled "Optical Cable Exit Trough." It includes three claims directed to a method of assembling a cable routing system, involving the steps of providing a lateral trough section, mounting a cable exit trough to the top edge of the lateral trough section, and routing cable upwardly and transversely to reach the cable exit trough. ADC asserts that Panduit's spillover junction infringes claims 1 and 2 of the '181 patent. Claim 1 reads:

1. A method of assembling a cable routing system comprising the steps of:

   providing a lateral trough section; mounting a cable exit trough to a top edge of the lateral trough section; routing a cable from the lateral trough section upwardly and transversely to the exit trough.

The parties dispute only the language "mounting a cable exit trough to a top edge of the lateral trough section." A "cable exit trough" is properly understood as a channel through which cable exits the lateral trough section. Contrary to ADC's arguments, the term "cable exit trough" does not include any bend radius control features. No such features appear in the claim.

The term "top edge" is not defined in the '181 patent to have any meaning other than its ordinary meaning. The word "top" is ordinarily known as "the highest point, level, or part of something." Webster's Third New International Dictionary, 2409 (unabridged ed. 1968). An "edge" is commonly understood to be the "relatively thin surface or side of any object bounded by plane surfaces." Id. at 722. A "top edge" is defined as "the narrow surface or side of a thin object." New Shorter Oxford English Dictionary, 784 (Thumb Index ed. 1993). Applying these ordinary meanings to the '181 patent, the term "top edge" means a narrow, uppermost surface of the sidewall that is parallel to the floor of the trough. The specification supports this interpretation, distinguishing between the side wall of the trough section and the "top edge." In Figure 1 and Figure 4 of the '181 patent, the sidewall is indicated by reference number 24, while the top edge is indicated by reference number 30. See Fiorella Decl., Ex. 1; see also the '181 patent, col. 2: 62-63 ("Side 24 includes a top edge 30."). Thus, the "top edge" does not include the side surfaces of the lateral trough walls.

2. Claim 1 "top member"

Bradford proposes that "top member" means "the uppermost part, point, surface, or end of a distinct part of a whole." Defendants propose that "top member" means "a distinct part of a whole that extends around the entire periphery of the uppermost end." The basic dispute over this term is Defendants' additional limitation of "that extends around the entire periphery of the uppermost end."

In support of their construction of "top member", Defendants again direct the Court's attention to the specification. Defendants note that in the specification, the "top member" refers to a component or part that extends around the entire periphery of the container. Defendants then observe that the "top member" also has subparts referred to as "sides". Therefore, Defendants argue, the "top member" must describe a complete circuit. Tr. at 69. In opposition, Bradford contends that Defendants are improperly importing structural limitations from the specification to the claims.

This issue harkens back to the discussion concerning the specification's treatment of "side walls" and "sides". The Court concluded then that the specification consistently treats these terms as separate components. Similarly, as Defendants correctly point out, the specification consistently treats the "sides" as being a subcomponent of the "top member". In
addition, the specification also states that the top member is "generally rectangular shaped", lending support to Defendants' contention that "top member" describes a complete circuit. '916 Patent, col. 12, ll. 24-28.

Accordingly, the Court holds that "top member" means "a distinct part of a whole that extends around the entire periphery of the uppermost end."

II.

Sage's '728 patent discloses a disposal container that allows a user to deposit hazardous medical waste without touching waste already in the container. Figure 3 of the patent, reproduced below, illustrates the claimed features. The disposal container 10 includes a container body 12 with an elongated slot 16 at its top. A barrier, having a first constriction 18 and a second constriction 20, restricts access to the interior of the container body. Closure 28 closes the container.

[SEE ILLUSTRATION IN ORIGINAL].

The only independent claim of the '728 patent (with emphasis to highlight disputed elements) reads:

1. A disposal container comprising:
   a. a hollow upstanding container body,
   b. an elongated slot at the top of the container body for permitting access to the interior of the container body,
   c. barrier means disposed adjacent said slot for restricting access to the interior of said container body, at least a portion of said barrier means comprising
      i. a first constriction extending over said slot, and
      ii. a complementary second constriction extending beneath said slot, and
   d. a closure disposed adjacent said slot.

The district court properly interpreted "top of the container body" to mean the "highest point, level, or part of." The court also properly interpreted "extending over said slot" to require that the first constriction be "above" the elongated slot. The patentee nowhere indicated any intention to deviate from these ordinary meanings of the claim terms. Thus, they control. See York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572, 40 U.S.P.Q.2D (BNA) 1619, 1622 (Fed. Cir. 1996) ("Without an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning.").

a. "Top Surface"

Claim 1 indicates that the tool holder is comprised of a top surface that is directly opposite a bottom surface with an intermediate surface between the two. '857 Patent, Col. 7, ll. 28-30. Claim 1 further advises that two planar abutment surfaces extend from the top surface, forming a dihedral right angle to each other, and also forming a right angle with the top surface. '857 Patent, Col. 7, ll. 31-38. Since the parties did not offer any definitions for the term "top surface" or "planar abutment surface," that are particular to the broaching trade, the Court assumes that persons of ordinary skill in the art would ascribe to these terms the same meanings that a lay person would ascribe. The Court thus relies on dictionary definitions that are consistent with the intrinsic evidence of the '857 Patent to construe these terms. See Altiris, 318 F.3d at
"Top" means the "highest point, level, or part of something." Webster's Third International Dictionary (1976) (hereinafter Webster's). Accordingly, the Court construes the term "top surface" to mean the highest part of the tool holder, above which nothing else extends.

G. "A Top Surface of the Housing" and "Extending Upward from a . . . Side of the Housing"

According to the parties' stipulation, these terms are used in claims 1 and 32. The term "top surface of the housing" is also used in claim 23. Insight and SureFire dispute the meaning of the terms. Glock initially stated that these terms do not require construction but later joined SureFire in opposing Insight's construction.

Insight contends that "a top surface of the housing" means "a surface that is exposed in an upward direction and is on top of the housing when it is oriented in its normal or typical operating orientation." Insight interprets "extending upward from a side of the housing" to mean that the structural members of the housing must extend upward, as upward is usually understood, with reference to the usual orientation of the weapon and the housing. SureFire apparently concedes that Insight's construction provides the usual meaning of "top" and "upward" but contends that those skilled in the art would disregard the usual meanings and instead would find any directional meaning in the terms. SureFire asserts that those skilled in the art would understand directional words, such as "top" or "upward," "to relate to specific orientations between parts of a device," so that changing the position of the device "does not change the relationship between the elements of the device." SureFire argues that those skilled in the art would understand "upward" in this context to mean "extending away from . . . a side of the housing in a direction normal to the surface of the housing."

To make that theory persuasive, SureFire must show that one skilled in the art would give directional words the meaning it asserts rather than the more ordinary meaning in common usage. See LizardTech, Inc. v. Earth Res. Mapping, Inc., 424 F.3d 1336, 1342 (Fed. Cir. 2005). The only support for the theory SureFire offers is its interpretation of the deposition testimony of Insight's owner and one of the inventors of the '901 patented device, Kenneth Solinsky. 5

SureFire states in its construction memorandum and reply that directional phrases would not have their ordinary meaning to one skilled in the mechanical arts, which would include trained mechanical design engineers, engineering technicians, design draftsmen, and those who have developed a basic mechanical aptitude. Despite the broad category described of those skilled in the art, SureFire did not provide a single affidavit from one skilled in the art to support its theory. Instead, SureFire offers the argument of counsel as to how weapons are used and how the terms are understood. Such argument without proper support is not persuasive.

In the part of the deposition cited by SureFire, Solinsky was not asked what one skilled in the art would understand directional terms to mean. Instead, SureFire's counsel asked Solinsky whether a device installed on top of the barrel of a weapon, rather than underneath the barrel, would infringe the '901 patent. Solinsky answered that he would have to think about that before answering, that it would depend on the "normal orientation of the device," and then reluctantly said that the specific device they were examining would infringe.

SureFire contends that Solinsky's opinion supports its construction of the terms "upward" and "top." Specifically, SureFire argues that Solinsky's infringement opinion means that one skilled in the art, like Solinsky, would understand that the directional terms in the patent do not have their common meaning because, based on that opinion, a device with structural members extending down from the device to the weapon would nevertheless be infringing. Solinsky's opinion, noting the "normal orientation of the device" and that a device could be turned "upside down," does not demonstrate that one skilled in the art understands such directional terms in a different light than their ordinary meanings. The court also does not find SureFire's argument persuasive in light of the explanations and the use of directional terms in the specification.

The specification describes some of the embodiments of the auxiliary device without a specific reference to direction. In one embodiment, the auxiliary device includes a housing with mounting members that extend "therefrom." 3:67. In another embodiment, the housing "is provided with structural members that extend from or form part of the housing." 4:64-5. In addition, the specification uses directional terms in other contexts with their common and ordinary meanings, as in the reference to the bottom of the weapon frame when describing the workings of the spring-biased mechanism and the location of the side rails "forward" of the trigger guard. 4:51-52 & 4:62.
The drawings all show the weapon in its expected upright position and the attachment mechanism oriented in the same directional framework. In describing the embodiment shown in figure 7, the specification explains that figure 7 shows a hollow housing to allow the gun frame to go through the housing, with the auxiliary device positioned "above the weapon frame," which is what the drawing shows. 10:17. The specification further explains that alternative designs for the auxiliary device are possible in which the device would be positioned on top of the weapon frame or on top of the barrel with the spring-biased mechanism located "on top of the weapon frame or on top of the barrel." 10:22-23.

Claims 1 and 32 are limited to an auxiliary device with a housing designed to have a structural member "extending upward from a first side" and "a second structural member extending upward from a second side." 10:54-57 & 12:43-46. The spring-biased mechanism is located on "a top surface of the housing." 10:67 & 12:56.

Taking those terms in the context of the patent as a whole and lacking any persuasive evidence to the contrary, the directional terms used in the patent have their ordinary meanings. The phrase "extending upward" means upward from the housing toward the weapon above the housing, with the weapon in its expected position as shown in the drawings. The top of the housing means the top with reference to the housing in its position under the weapon, again, with the weapon in its expected position as shown in the drawings.

Gargoyles argues that the inventor, Mr. Burns, acted as his own lexicographer and defined the term "toric" broadly to mean only that the radii of curvature in the horizontal meridian differ from the radii of curvature in the vertical meridian. That relatively broad definition of "toric," Gargoyles contends, is made clear by the claims and Specification of the patent and is not further limited by the prosecution history. Viewing that definition as unambiguous, Gargoyles urges this Court to limit its inquiry to the intrinsic evidence and to reject the more limited definition proposed by Aearo. Moreover, Gargoyles contends, even extrinsic evidence such as the dictionary and scientific texts contemplate a broad definition of "toric."

Aearo responds that the claims of the '611 Patent fail to define "toric" and that the Specification and prosecution history demonstrate that the inventor gave the word "toric" its ordinary meaning such that it describes objects having a single constant radius of curvature in each meridian. In addition, Aearo contends that, in spite of suggestions in the Specification and the prosecution history, the intrinsic evidence leaves the definition of "toric" ambiguous.

Aearo thus urges this Court to consult extrinsic evidence, including three treatises in the fields of optics and ophthalmology. It argues that the terms "toric" and "toroidal," as used in those treatises, are meant to include only those objects with two, and only two, different radii of curvature in the opposite meridians, as exemplified by the shape of a doughnut or a barrel.

- The Specification

While neither the claims themselves nor the Specification of the '611 Patent expressly defines the word "toric," parts of the Specification describing the shape and function of the lenses are relevant to construing that term.

Both parties cite the "Best Mode" section of the Specification, which states:

The lenses 12 have toric inner and outer surfaces of uniform radius of curvature throughout . . . The lenses 12 by utilizing a constant radius of curvature in each meridian, have substantially better optical properties than conventional eyeglasses which utilize lenses having relatively little curvature in the front and substantially greater curvature at the sides.

'611 Patent, col. 2, 11. 59-64. Gargoyles argues that the foregoing description applies only to the best mode, but not to other embodiments of the patent, and does not limit the word "toric" to lenses with a "constant radius of curvature." Because the word "toric" is qualified in the Best Mode section but not elsewhere, Gargoyles contends that the patented lenses have a constant radius of curvature only in one embodiment while they have varying radii of curvature in others.
Aearo responds that, because the preferred embodiment discloses only one method of practicing the invention, the claims are limited to that embodiment and thus incorporate the "constant radius of curvature" limitation in the word "toric." In support of that construction, Aearo cites the Federal Circuit Court of Appeals decision in Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545 (Fed. Cir. 1996).

In the Modine case, however, the court was interpreting the term "relatively small" to describe the hydraulic diameter of a condenser. Id. at 1551. That court read the term "relatively small" as limited to the particular measurements disclosed in the preferred embodiment because, during the prosecution of the patent-at-issue, other embodiments with wider measurements had been rejected in light of prior art condensers with wider diameters. Id. at 1553-54. In the present case, because the patent examiner did not reject embodiments with varying radii of curvature in the horizontal meridian, Modine is inapposite.

This Court, therefore, agrees with Gargoyles that the quoted description of the Best Mode does not limit the meaning of "toric" to lenses with a "uniform radius throughout" the horizontal meridian but, rather, implies that some "toric lenses" have varying radii in that meridian. See Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed. Cir. 1988) (stating that a claim is not limited to the best mode or any particular embodiment).

On the other hand, the "Background Art" and "Disclosure of the Invention" sections of the Specification in the '611 Patent explain that the shape of the lenses differentiates the disclosed invention from lenses disclosed in the prior art whose varying radii produced distortion. '611 Patent, col. 1, 11. 36-46, 60-62. If one of the objects of the "toric lenses with radii of curvature that are selected for zero-power" was to "provide eyeglasses … having excellent optical properties," those lenses cannot have "quickly changing" radii of curvature that thereby distort vision. That limitation of the disclosed lenses is not, however, specifically associated with the term "toric." Indeed, the differentiation from lenses which distort vision because of their radii of curvature relates more logically to the phrase "radii of curvature that are selected to provide zero power" rather than to "toric."

This Court concludes that the Specification does not provide an unambiguous definition of the term "toric lens" despite the fact that it defines "radii of curvature that are selected to provide zero power" to exclude lenses with "relatively little curvature at the front" and "curvature increasing substantially toward the outer edges of the glasses," i.e., lenses whose "radius of curvature in the horizontal meridian quickly changes" thereby producing distortion. '611 Patent, col. 4, 11.17-18 & col. 1, 11. 36-38, 42-43 (emphasis supplied).

b. The Prosecution History

Like the claims and the Specification of the '611 Patent, the PTO file contains no express definition of "toric." The inventor's attorney, nevertheless, made a single comment which implies that a "toric lens" has a constant radius in the horizontal meridian.

In a letter dated January 16, 1984, Burns' attorney discusses a French patent issued to Lissac, which the PTO examiner had identified as disclosing toric lenses. Id. at 5. Having translated the French text in the patent, Burns' attorney explains that, according to that text which describes "visors made by molding . . . on spherical molds," the Lissac lenses are not toric but are instead spherical. He then differentiates a spherical lens, which has the same radius of curvature in both the horizontal and vertical meridians from "a toric lens, [in which] the radius of curvature of the lens is different in both the vertical and horizontal meridians." Id. at 6. Suggesting that the examiner should rely on the French text rather than the accompanying drawings, Burns' attorney points out that the drawings in the Lissac patent do not show a spherical lens because "the radius of curvature of the lens in each meridian varies along the length of the lens [which] would not be true in either a spherical or a toric lens." Id. (emphasis added).

Aearo argues that the latter comment settles the definition of "toric" as used in the '611 Patent and limits it to lenses with constant radii of curvature in each meridian. Gargoyles responds that the comment should be ignored because it was a gratuitous comment that had no bearing upon the claim language or Burns' ultimate success in obtaining his patent. This Court finds that, although the comment by Mr. Burns' attorney may shed light upon the common meaning of the word "toric," when taken in context, it fails to resolve all ambiguity with respect to the intended meaning of the disputed term as used in the '611 Patent.

Having reviewed the claims of the '611 Patent, the Specification and the PTO file, this Court finds that the word "toric" is
used in accordance with its ordinary meaning, but that the intrinsic evidence leaves that meaning ambiguous to those not skilled in the art of optics. This Court, therefore, has consulted dictionary definitions and treatises submitted by the parties and has considered the explanatory testimony of their experts at the limited Markman hearing in order to determine the ordinary meaning of the word "toric" in the field of optics. See Vitronics, 90 F.3d at 1584 n.6 (noting that judges may consult technical treatises and dictionaries "at any time" and "may also rely on dictionary definitions when construing claim terms so long as [they do] not contradict any definition found in . . . the patent documents").

c. The Extrinsic Evidence

Standard English dictionaries define the word "toric" as an adjective used to describe the surface of a lens having the form of a "torus" or part of a "torus." Random House Dictionary of the English Language 1998 (2d ed. 1987); Concise Oxford Dictionary of Current English 1130 (7th ed. 1982). A "torus" is a doughnut-like geometrical object formed by rotating a closed curve or conic around a line in its plane but not intersecting it. Concise Oxford Dictionary of Current English 1131 (7th ed. 1982) ("(Geom.) closed surface or solid formed by rotating closed curve, esp. circle, about line in its plane but not intersecting it [L, = swelling, bulge, cushion, etc."]"); Random House Dictionary of the English Language 2000 (2d ed. 1987) ("(Geom. a. a doughnut-shaped surface generated by the revolution of a conic, esp. a circle, about an exterior line lying in its plane. b. a solid enclosed by such a surface.")

The rotation of the "closed curve" around the line creates a single radius of rotation, which corresponds to one, necessarily constant radius of curvature in a "toric" object. Similarly, if the rotating "closed curve" is itself a circle, the radius of that circle, which corresponds to the second radius of curvature in the "toric" object, is by definition, constant. If, however, the rotating "closed curve" or "conic" is an ellipse, which has varying radii of curvature, then the resulting "torus" will have varying radii of curvature in one meridian.

Because this Court must construe "toric lens" in accordance with its ordinary meaning to one skilled in the art of optical engineering, the crucial issue is whether, in the field of optics, the "torus" shape used as a model for "toric lenses" is limited to those shapes generated by the rotation of a circle around a line, and by no other kind of closed curve.

At the limited Markman hearing on May 8, 1998, the parties presented extrinsic expert testimony (F. Dow Smith, Ph.D. for the plaintiff and Warren Smith and Kevin Salce for the defendant) with respect to the meaning of the word "toric" to a person of ordinary skill in the arts of non-prescription eyewear design and optical engineering. That testimony, together with other evidence before the Court, demonstrated that the person of ordinary skill in those arts would understand that a "toric lens" is primarily one in which the horizontal and vertical meridians have different radii of curvature. The difference between the radii in opposite meridians is the characteristic which distinguishes toric lenses from two other common lens shapes, i.e., flat lenses (which have no curvature) and spherical lenses (which have the same radius of curvature in both meridians). Although such a person might also know that, due to manufacturing limitations, the commonly manufactured "toric" lenses are "circular toric" and, therefore, have constant radii of curvature in each meridian, this Court finds that the word "toric" itself is not so limited. 2 For example, "toric" lenses include not only "circular toric" lenses but also "ellipsoidal toric" lenses (which have varying radii of curvature in one meridian).

--- Footnotes ---

2 This Court does not rely upon the numerous scientific texts discussing "toric" lenses that were submitted by the parties in support of their respective motions for summary judgment because the testimony of Kevin Salce and F. Dow Smith demonstrates that a person of ordinary skill in the relevant arts would not consult such texts.

--- End Footnotes ---

Based upon the intrinsic evidence (particularly the "Best Mode" section of the Specification), the dictionary definitions and expert testimony at the limited Markman hearing, this Court construes the term "toric lens" to mean a lens which is curved so that the radii of curvature in the horizontal and vertical meridians are different.
Torque

Claims in the '715 Patent contain the terms "torque-on-bit" and "torque response." Baker Hughes contends "torque-on-bit" and "torque response" mean "forces responsive or reactive to drill bit rotation (which typically is a force or are forces in a direction other than the direction of drill bit rotation)." ReedHycalog argues "torque-on-bit" and "torque response" mean "resistance to rotation." The dispute centers on whether torque is limited to forces opposite the direction of drill bit rotation. ReedHycalog's definition limits torque to forces opposite drill bit rotation; Baker Hughes's construction is not so limited.

There is no support to limit "torque-on-bit" or "torque response" to the torque in the direction opposite of drill bit rotation. Thus, the terms are not so limited. Further, a lay jury will understand the term "torque," and therefore the terms "torque-on-bit" and "torque response" require no construction. 16

--- Footnotes ---
16 Ref. Nos. 18 and 19 of Appendix B contains the disputed terms and their constructions.

--- End Footnotes ---

Similarly, the preamble of claim 33 of the '631 Patent claims "a method of drilling . . . without generating an excessive amount of torque-on-bit." A lay jury will understand the term "excessive," and therefore that term does not require construction. 17

--- Footnotes ---
17 Ref. No. 34 of Appendix B contains the disputed term "without generating an excessive amount of torque-on-bit" and its construction.

--- End Footnotes ---

We turn first to the court's construction of the terms "non-tortuous copy path" and "tortuous bend." The meaning of these two claim terms, which are used to define the degree of bending that the edible sheet undergoes during its passage through the photocopy machine, depends upon the meaning of "tortuous" and "non-tortuous." This is so because the parties apparently agree that a non-tortuous copy path is a path that is free of "tortuous bends." As described above, the district court held that "[a] bend is tortuous if it significantly deforms the line preceding it." Guttman, slip op. at 4. As Guttman notes, the trial court did not explain the basis of this definition. The dictionary defines "tortuous" as "marked by repeated twists, bends, or turns." Webster's Third New International Dictionary 2414. This cannot be the proper definition of "tortuous" as used in the claims, however, because it simply makes the phrase "tortuous bend" redundant, without providing any insight into the crucial issue of how curved a bend may be before it becomes "tortuous" within the meaning of claim 11. Relying on the intrinsic evidence, Guttman asserts that a non-tortuous copy path is one that, while potentially curved, contains no curves sharp enough to sacrifice the survivability of the edible sheet.

Path 18 of Figure 1 of the '530 patent illustrates what the specification describes at column 3, line 59 as a tortuous copy path:

[SEE FIGURE 1 IN ORIGINAL]

Path 18 follows a 180 degree curve, which is typical of the type of bent copy path in most commercial photocopy machines. However, while Figure 1 illustrates a bend that falls within the definition of "tortuous," it does not answer whether other, less extreme bends might also fall within that definition.
The specification does not explicitly define tortuous (or non-tortuous). The specification, however, is not entirely silent as to what a "non-tortuous copy path" is. In column 4, the patent describes a copy path free of "any tortuous bends or significant curves," such as the 180 degree curve shown above, so as to enhance survivability of the substrate sheet. '530 Patent, col. 4, lines 29-30. Thus, the specification indicates that a non-tortuous path is one that enhances survivability of the edible sheet.

Further disclosures in the specification are consistent with the meaning espoused by Guttman. As noted above, traditional photocopy machines were thought to be incompatible with edible sheets in part because the paper is too delicate to survive passage through a copy path with extreme curves. The specification describes this problem as follows: "Most edible substrate sheets are relatively flimsy sheets, and so would not likely survive a pass through the machine along the copy path. Indeed the copy path in such machines is quite tortuous making them unsuitable for photocopying onto either flimsy or rigid edible sheets." Id. at col. 2, lines 27-33. Thus, it is clear that a tortuous bend is one that an edible substrate sheet "would not likely survive."

The specification teaches that providing a "substantially straight" copy path is one solution to this problem:

The tortuous path is thus usually provided between the copy paper source, such as a drawer in the machine, and the reproducer mechanism in the terminal copying portion of the copy path. To this end . . . the tortuous copy path is interrupted and a substrate input is defined . . . such that the edible sheet (and carrier) will traverse a substantially straight copy path so as to enhance survivability of the sheet as it passes through the machine, while also reducing the areas of the machine that could be gummed-up by the edible sheet.

Id. at col. 3, lines 5-16. Kopykake seizes on this language in the specification (and similar language in the prosecution history) to support its proposed claim interpretation, namely that "non-tortuous copy path" means a substantially straight copy path. However, while we agree that a substantially straight path is non-tortuous, we do not agree that the claim language should be limited to substantially straight copy paths. The inventor clearly contemplated using the invention in machines with curved, but non-tortuous, copy paths. For instance, the specification notes that putting the edible substrate sheets on a carrier sheet with tape down the side "helps protect edge 130 from snagging and is particularly advantageous for use in photocopying machines where the paper path is curved as opposed to straight." Id. at col. 5, lines 18-20. Furthermore, the other independent claims explicitly recite a "substantially straight copy path," suggesting that the applicant chose "non-tortuous copy path" to mean something different from, and presumably broader than, a substantially straight copy path.

Were there any doubt as to the correctness of Guttman's interpretation, the prosecution history provides an explicit definition of the contested claim language. The limitations to a "non-tortuous copy path" and lack of "tortuous bends" were added via amendment. The reason for the amendment is unclear from the record on appeal. However, the remarks accompanying the amendment explain that

it will be understood that the term "non-tortuous," as used by Applicant, is intended to cover a copy path that may be curved, but is free from any bends that would tend to sacrifice the survivability of the substrate. For example, on Page 10, lines 8-10 of the disclosure, Applicant states that "tape 132 helps protect edge 130 from snagging and is particularly advantageous for use in photocopying machines where the paper path is curved as opposed to straight (emphasis added)." Accordingly, Applicant clearly contemplates a curved copy path, but one that is free from tortuous bends that would tend to impair the intended properties of the edible web.

Based on this language, Guttman asserts that a "non-tortuous copy path" is simply "a path that can be curved, but which is free from bends that would tend to sacrifice the survivability of the substrate."

We see no reason to deviate from the definition espoused by the applicant during prosecution, and therefore we agree with Guttman that the correct definition of "non-tortuous copy path" is a path that, while not necessarily straight, has no curves sharp enough to sacrifice the integrity of the edible substrate sheet. By extension, a "tortuous bend" is a bend sufficiently sharp to sacrifice the integrity of the substrate sheet. We turn now to the other disputed claim term: photocopy machine.

4202

1. Infringement
In addressing infringement, the district court found that Cordis' microcatheter products were likely to fall within the scope of claim 12 of the '768 patent. On appeal, Cordis contends that the court erred in its claim construction and that such error led the court to conclude that Target established a likelihood of success on the merits. We agree.

Determining whether a patent claim is infringed requires a two-step analysis: "First, the claim must be properly construed to determine its scope and meaning. Second, the claim as properly construed must be compared to the accused device or process." Carroll Touch, Inc. v. Electro Mechanical Sys., 15 F.3d 1573, 1576, 27 U.S.P.Q.2D (BNA) 1836, 1839 (Fed. Cir. 1993). Claim construction is a question of law, which we review de novo. Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2D (BNA) 1321, 1329 (Fed. Cir. 1995) (in banc), aff'd, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). In construing a claim, we consider the language of the claim, the specification, and the prosecution history. Nike Inc. v. Wolverine World Wide, Inc., 43 F.3d 644, 646, 33 U.S.P.Q.2D (BNA) 1038, 1040 (Fed. Cir. 1994).

Claim 12, as amended through reexamination, contains three principal elements: (1) it is comprised of at least three segments, (2) it increases in flexibility from the proximal to the distal end, with the distal-most segment being at least 5 cm long, and (3) it must be sufficiently flexible that to travel along a tortuous path of at least 5 cm through vessels of less than about 3 mm in diameter said target site said elongate tubular member must be guided with a guidewire . . . .

It is this third element, the structural limitation of "sufficiently flexible," that is the focus of the current dispute. The language of the claim imposes the structural limitation not through the objective mechanical measurements one might expect, but by gauging the microcatheter's ability to traverse a "tortuous path" with or without the use of a guidewire.

The district court jettisoned the clear language of the structural limitation through the imposition of a standard of safety. The court concluded that even if the catheter was physically capable of traversing "a path of less than three mm lumen diameter over a path length of over five cm without a guidewire [it would] still infringe the '768 patent if it cannot be done in a medically safe and prudent matter."

Cordis correctly argues that the claim language is presenting a physical, albeit awkward, flexibility limitation and it was improper for the court to stray outside the confines of the claims, the specification and the prosecution history. Cf. Vitronics v. Conceptronic, Inc., 90 F.3d 1576, 39 U.S.P.Q.2D (BNA) 1573 (Fed. Cir. 1996). Under the claim as issued, a microcatheter which is capable of traversing a tortuous path without the guidewire would not be sufficiently flexible to meet this structural limitation of the claimed device, regardless of whether the procedure was safe or whether the device was intended to be used with a guidewire.

The specification provides little assistance in construing "sufficiently flexible/must be guided" language. However, the structural limitation interpretation is borne out by the prosecution history. The prosecution history reveals that the "sufficient flexibility/must be guided" language was added during the course of the reexamination. Target repeatedly focused on this particular language as providing a measure of flexibility which distinguished the prior art and overcame the examiner's concerns. Cordis points to a few examples from the reexamination proceedings:

Of most importance is the clarifying limitation relating to the overall flexibility of the claimed devices - that the catheters are of such flexibility that they must use a guidewire to reach a chosen spot within the tissue.

****

Each of the claims now requires that the claimed catheter be sufficiently flexible that it must be passed through the body to the target site using a guidewire.

****

The catheters of the claims, in contrast [to the prior art], must be sufficiently flexible that they cannot pass through the vasculature to the target site without the aid and direction of a guidewire.

****
The claims positively recite the requirement that the claimed catheters are so lacking in inherent stiffness that they must be passed to the intrabody target site with a guidewire.

At no point in the prosecution history does Target ever address a standard of safety. Nor should it have, to do so would shift the focus to the application of the invention, as the district court did, and obscure the fact that it is an apparatus which is patented.

We conclude that the "sufficiently flexible/must be guided" language was intended only to elucidate the structural parameters of the microcatheter. It is apparent from the claim language, read in light of the specification and the prosecution history, that the standard of safety and reasonableness is an extrinsic, improperly imposed, standard.

The second aspect of the infringement analysis is the comparison of the allegedly infringing product with the properly construed claim. Cordis has provided both video and written declarations aimed at demonstrating that its microcatheter products are capable of traversing the tortuous path without a guidewire. As the parties have argued, in reviewing the declarations it becomes immediately apparent that we must construe the claim term "tortuous path."

Target argues that the five elements of a "tortuous path" are set forth in the specification, including: (a) a number of bends, some of which may be 90 degrees or more, (b) small vessels, typically with lumen diameters of less than about 3 mm, and (c) a total path length within the target tissue of at least about 5 cm, (d) accessible by a guidewire 18 mil or smaller of the type described above, but being too delicate and or tortuous for accessing by significantly larger guidewire, and (e) the requirement that the path include vessels that branch off the more proximal vessels of the path at greater than a right angle.

Cordis argue that a valid construction should only include the first three elements, because after enumerating these characteristics the specification concludes the paragraph with "[a] path having these characteristics is defined herein as a tortuous path...." However, as Target points out, the next paragraph explicitly expands on the description, stating that a tortuous path is "further characterized by" the last two elements. The district court merely perpetuates its improper standard of safety and concludes that a tortuous path is one which cannot be accessed without a guidewire. Insofar as the claims must be read in light of the entire specification, not just advantageous snippets, we adopt Target's construction of "tortuous path."

The district court's erroneous construction of claim 12 affected its analysis of likelihood of infringement. While we do not rule on infringement, as there are unresolved factual issues, we find that the district court clearly erred in determining that there was a likelihood of infringement.

The invention of the '701 patent activates its shredding function using a "touch switch." Fellowes maintains that the term "touch switch" should be construed to mean a switch that requires physical contact in order to be activated. (See Fellowes's Opening Brief at 20.) Michilin, however, contends that the term "touch switch" means "touch switch, or any other kind of switch." (Michilin's Opening Brief at 10.)

Michilin conceded that "the conventional definition of a 'touch switch' means a switch that must be physically touched to be activated" (Fellowes's Opening Brief, Ex. H, Michilin's Response to Fellowes's Requests for Admissions at 4), and now cites no alternative definition of touch switch offered in the '701 patent. This matter, then, is conclusively established pursuant to Federal Rule of Civil Procedure 36(b). Fed. R. Civ. P. 36(b) ("Any matter admitted under this rule is conclusively established unless the court on motion permits withdrawal or amendment of the issue."). Moreover, Michilin did not contest at the supplemental scheduling conference held on March 29, 2006 that a touch switch requires physical contact, and Michilin II granted Fellowes's request for summary judgment of literal noninfringement. Id., 433 F. Supp. 2d at 12-13. Michilin cannot now revive an argument it opted to waive. In any case, the ordinary meaning of touch switch requires the switch to be physically touched. The claim language is clear and unambiguous. "Touch switch" means a switch that requires physical contact in order to be activated.
1. Claims 1 and 9: construing "toward"

Claims 1 and 9 speak of a first and second speaker driver, each of which is mounted in a sound cabinet and has an axis "directed toward the listening area" (emphasis added). Defendant urges the court to construe "toward" as "generally perpendicular to the front plane collectively defined by the sound cabinets to project sound into the listening area." Plaintiff maintains that "toward" should be interpreted as "in the direction of," which is the definition found in Merriam Webster's Collegiate Dictionary (10th ed. 1993).

According to the "Background of the Invention," traditional stereo recording involved two channel signals, a left and a right, each of which had its own speaker driver housed in its own speaker cabinet. In a two-channel system, if the left and right speaker drivers are pointed inward, toward the listener, their sound presentations will merge together and reinforce the center image, but degrade the spaciousness of the presentation. If the speaker drivers are pointed forward or slightly outward, greater spaciousness is achieved at the expense of degrading the center image.

Some efforts at enhancing reproduction of two channel systems have utilized "reflected sound" that is "bounced" off the back and side walls. The "Background of the Invention" notes, however, that "adding additional artificial reflected sound into the room beyond that reflected sound which already exists in the original musical recording, injects a certain artificiality to the replayed music and creates a loss of direction of the course and loss of musical sound integrity."

Ultimately, three-channel systems comprised of a left channel signal, right channel signal, and center channel signal were developed. A challenge of those systems, however, was positioning a separate speaker driver for the center channel. The "Background of the Invention" identifies two drawbacks in particular with respect to the third speaker driver: (1) the spatial and aesthetic considerations of placing a third speaker cabinet within a room, and (2) managing the dominance of the center channel, which often carries more information than the left and right channels.

The stated objectives of the '680 patent are, among other things, to, (1) eliminate the necessity of positioning an additional speaker driver and cabinet separate from the left and right speaker drivers, and (2) maintain the integrity of the center channel signal and the sound image produced therefrom within the listening area while eliminating the distinct perceived location of a center channel speaker driver. To this end, the "Summary of the Invention" provides:

The present invention addresses the above-discussed objectives with a loudspeaker system which utilizes a unique configuration of speaker drivers which are coupled to a multiplicity of audio signal channels of an audio signal generator to more realistically recreate a musical recording in a listening area similar to the sound of the music on stage.

To that end, a loudspeaker system comprises two spaced apart cabinets for housing speaker drivers…. The sound cabinets are positioned to collectively define a front plane which generally faces the listening area. A first speaker driver is mounted in one of the cabinets while a second speaker driver is mounted in the other of the cabinets. The first and second speaker drivers are arranged to have their axes generally perpendicular to the defined front plane of the sound cabinets to project sound into the listening area…. The system further comprises third and fourth speaker drivers which are positioned respectively within the first and second cabinets next to but slightly spaced from the first and second drivers in those cabinets…. The axes of the third and fourth drivers are oriented at an angle with respect to the plane defined by the sound cabinets and with respect to the axes of the first and second drivers to which they are adjacent. The third and fourth speaker drivers cooperate to create a third channel sound image, such as a center channel sound image with center channel frequency components in the listening area forward of the sound cabinets. Preferably, the center channel sound image is created generally between the right and left channel sound images in the listening area. To that end, the axes of the third and fourth speaker drivers are angled with respect to the generally parallel axes of the first and second speaker drivers at an angle in a range of approximately 20 [degrees] -- 45 [degrees] are directed forward into the listening area and inwardly between the parallel axes of the first and second speaker drivers such that the axes of the third and fourth speaker drivers intersect forward of the sound cabinets in the listening area.
The focused third channel drivers create a center channel sound image while eliminating the need for a separate dedicated sound cabinet with speaker drivers for playing the center channel. The loudspeaker system creates an accurate and well-balanced sound image with direct sound from each channel as opposed to various artificial sound images utilizing the addition and subtraction of the left and right channels and artificially created reflected sound.

The "Detailed Description of Specific Embodiments" further provides:

The sound perceived by [the] listener 16 is created by primarily direct sound images which recreate the sound, such as music, as it was recorded as opposed to a system which attempts to create sound environments by utilizing artificially reflected and/or electronically modified signals, e.g., L-R, R-L techniques.

According to defendant, the language describing the axes of the outer drivers (the first and second drivers) as being "generally perpendicular" to the front plane of their respective sound cabinets and "generally parallel" to one another, as well as the discussion of using direct (as opposed to reflected) sound, compels the court to adopt defendant's proposed construction of "toward," as perpendicular. The court disagrees.

In the instant case, the disputed claim language in claims 1 and 9 describes a speaker driver mounted in a cabinet and having an axis directed "toward" the listening area. As noted above, in the absence of an express intent to impart a novel meaning to claim terms, or some ambiguity of claim terms requiring clarification, the words used in a claim are deemed to have their ordinary and customary meaning as understood by one of ordinary skill in the art. Here, there is nothing in the specification of the '680 patent indicating that "toward" is intended to convey anything other than its ordinary and customary meaning: "in the direction of."

Two of the stated objectives of the '680 patent are to, (1) create a center channel image while eliminating the necessity of positioning an additional speaker driver and cabinet separate from the left and right speaker cabinets, and (2) eliminate the distinct perceived location of a center channel speaker driver. Consistent with these objectives, the "Field of the Invention" states that "the present invention relates generally to a loudspeaker system for creating multiple sound images and more particularly to a loudspeaker system which produces multiple sound images in a listening area with a focused center source image from two speaker driver locations."

The '680 patent claims a system comprising two speaker cabinets, each of which has two drivers inside. When the cabinets are adjacent to one another, one of the drivers in each cabinet has an axis directed forward to the listening area, and the other driver in each cabinet is "directed inwardly to a location in the listening area" between the two cabinets. The inwardly facing drivers create a third (center) channel image between the sound images created by the other (outer) two drivers.

Although it seems clear from the claim language that the inwardly-facing drivers are angled so that they create a channel image between the sound images created by the other (outer) two drivers, nothing in claims 1 and 9 implies that the axes of the outer drivers be, as defendant argues, "generally perpendicular to the front plane collectively defined by the sound cabinets to project sound into the listening area." Claims 1 and 9 simply use the word "toward" to describe the orientation of the outer drivers in relation to the listening area and, in this context, it does not appear that "toward" needs further clarification.

Moreover, as discussed below, nothing in the specification compels such a narrow construction of "toward." Plaintiff has not assumed the role of lexicographer by explicitly defining "toward" to mean something other than its customary and ordinary definition. Nor has plaintiff used words of "manifest exclusion or restriction" that represent a clear disavowal of claim scope.

The language in the specification -- specifically, the "Summary of the Invention" and "Detailed Description of Specific Embodiments" -- that speaks of generally perpendicular axes and parallel axes does not represent an explicit definition that departs from the ordinary and customary meaning of "toward." The references to "generally perpendicular" and "parallel" in the context of the orientation of the outer speaker drivers are few and far between: "generally perpendicular" is used three times 3 in the specification, and "parallel" and "generally parallel" are each used once. Compare Microsoft Corp. v. Multi-Tech Systems, Inc., 357 F.3d 1340, 1348 (Fed. Cir 2004) (concluding that communications between the local and remote sites of a the claimed invention had to occur directly over a telephone line in light of, among other things, specification's
"roughly two dozen" references to data transmission "over or through a telephone line").

3 One of these instances, contained within the "Detailed Description of Specific Embodiments," provides: "Preferably, the front face surfaces 26 of the sound cabinets 18, 20 are generally planar and exist in a plane parallel to the front face of the speaker drivers 22, 24 and generally perpendicular to the respective axes 23, 25. The speaker drivers 22, 24 and their respective axes, 23, 25, define an imaginary sound plane 28 forward of the sound cabinets 18, 20 and generally facing the listening area. The defined plane 28 is an imaginary reference and will be utilized to define the position and orientation of the various speaker drivers and their axes in accordance with the principles of the present invention." (Emphasis added.)

Defendant directs the court's attention to SciMed Life Systems, Inc. v. Advanced Cardiovascular Systems, Inc., 242 F.3d 1337 (Fed. Cir. 2001), for the proposition that characterizing a particular configuration as part of the "present invention," as in the instant case, is "strong evidence" that limits the scope of a patent's claims. SciMed is distinguishable in several important respects from the instant case, however.

Sci-Med involved three patents for balloon dilation catheters. At issue was whether the common specification of the three patents limited the scope of the asserted claims to catheters using one configuration of passageways, or lumens, as opposed to another. The SciMed court described the twelve references to "annular inflation lumen" included within the specifications' characterization of the "present invention" as "strong evidence that the claims should not be read to encompass the opposite structure." Id. at 1343. Moreover, the SciMed court was also influenced by language in another area of the specifications that characterized the annular inflation lumen as the "basic sleeve structure for all embodiments of the present invention contemplated and disclosed herein." Id. Last, the SciMed court emphasized that the three patents at issue "distinguished the prior art on the basis of the use of dual lumens and pointed out the advantages of the coaxial lumens used in the catheters that [were] the subjects of the SciMed patents." Id.

To begin, SciMed, in contrast to the instant case, involved only two conceivable choices: coaxial lumens (which used an annular inflation lumen) and dual lumens (which did not use an annular inflation lumen). Further, in contrast to the patents at issue in SciMed, the '680 patent does not describe "generally perpendicular" axes as the basic configuration for "all embodiments of the present invention contemplated and disclosed herein." See id. Nor does the '680 patent distinguish or criticize prior art on the basis of the outer speaker driver configuration.

The instant case involves only a handful of references to "generally perpendicular," "generally parallel," and "parallel" (in the context of the configuration of the axes of the outer drivers). 4 These few references simply do not constitute an "explicit definition" that would warrant departing from the customary and ordinary meaning of "toward."

4 It is worth noting that, with the exception of the example described in footnote 3, none of the references to "parallel," "generally parallel," and "generally perpendicular," is even in the same paragraph as the phrase "in the present invention." Compare Watts v. XL Systems, Inc, 232 F.3d 877, 883 (Fed. Cir. 2000) ("The specification actually limits the invention to structures that utilize misaligned taper angles, stating that 'the present invention utilizes [the varying taper angle] feature.'").

Alloc, Inc. v. ITC, 342 F.3d 1361 (Fed. Cir. 2003), relied on by defendant, is similarly distinguishable. In concluding that the patentee in that case invoked the added limitation "play," the Alloc court noted that the specification criticized prior art floor systems without play, id. at 1369, and that the patentee invoked play to overcome the prior art during prosecution of its parent patent, id. at 1372. According to the court, "Because the applicant invoked play to overcome the prior art... Alloc cannot now contend that the '621 patent claims a flooring system and method for installing that system without play." Id. In the instant case, there is simply no comparable evidence from the prosecution history that plaintiff expressly disavowed outer speaker driver configurations that did not involve "generally perpendicular" axes.
The specification's criticism of reflected sound and references to "primarily direct sound" do not compel a contrary result. First, depending on the placement of the speakers and the dimensions of the room, the axes of the drivers at issue could be angled outward without creating reflected sound. For example, if the drivers were angled outward to some degree and not placed too close to the side walls, the sound images emanating therefrom could reach the listening area before bouncing off of the side or back walls. This would result in the delivery of "primarily direct sound" and would further minimize artificially created reflected sound.

Second, to the extent that the "Background of the Invention" criticizes reflected sound, it should be noted that such criticisms are discussed in the context of two-channel stereo systems, as opposed to the three-channel system contemplated by the '680 patent. Thus, when read in context, the specification's criticisms of reflected sound and its references to "primarily direct sound" do not constitute a disavowal of claim scope.

The court recognizes that all of the figures contained within the specification show outer drivers facing forward, with their axes perpendicular to the front of the speaker cabinets. However, as the Federal Circuit has noted, "[Federal Circuit] case law makes clear that a patentee need not describe in the specification every conceivable and possible future embodiment of his invention." CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002) (internal quotation omitted). See also Teleflex, 299 F.3d at 1328 ("[The Federal Circuit has] cautioned against limiting the claimed invention to preferred embodiments or specific examples in the specification.") (Quotations omitted.).

In the absence of any indication that plaintiff intended to depart from the ordinary and customary meaning of the word "toward" in claims 1 and 9, the court declines to adopt defendant's proposed claim construction. Rather, the court concludes that "toward," as used in claims 1 and 9, should be construed according to its dictionary definition, which is "in the direction of." Consistent with this conclusion, the court also declines to read analogous limitations into claims 15 and 23, which require "adjacent" sound images from the outer drivers.

Having reached that conclusion, the court notes that it questions whether the distinction between its construction and defendant's construction is merely academic. Even under defendant's construction, the drivers are oriented "to project sound into the listening area." To the extent that defendant's construction calls for "generally perpendicular" axes to achieve that end, the court notes that "generally perpendicular" is not as precise as "perpendicular." Accordingly, even under defendant's proposed construction, the question of infringement would necessarily be left to a jury.

**A. "a toy device for the amusement of pet animals"**

The first disputed language, "a toy device for the amusement of pet animals," comprises the preamble of Claim 1. As a general rule, preambles are not construed as limiting the claims except in those instances where they recite "essential structure" or where they are "necessary to give life, meaning, and vitality to the claim." Catalina Mkts. Int'l, Inc. v. Coolsavings.com, 289 F.3d 801, 808 (Fed. Cir. 2002) (citation omitted). Thus, generally, "a preamble is not limiting where a patentee defines a structurally complete invention in the claim body and uses the preamble only to state a purpose or intended use for the invention." Id. (citation omitted). However, a patentee's "clear reliance on the preamble during prosecution to distinguish the claimed invention from the prior art transforms the preamble into a claim limitation because such reliance indicates use of the preamble to define, in part, the claimed invention." Id. Thus, statements of intended use may limit the claims in those instances where the patentee "clearly and unmistakably relied on those uses or benefits to distinguish prior art." Id. at 809.

In this instance Plaintiff clearly relied on use specified in the preamble to distinguish from the Postings reference (U.S. Pat. # 1,699,308) when, in a response to the USPTO examiner's initial rejection, he characterized Postings as an "exercising device" and noted that the device in Postings 'clearly has no 'amusement' value to the animals whatsoever." (Def's Ex. B at 33-36 (emphasis and quotations in original).) Plaintiff thereby relied on the "amusement" element of the preamble to define his claimed invention and to distinguish it from a prior art reference. Thus the preamble must be construed as limiting inasmuch as the claim requires an element of "amusement."

Plaintiff argues, and at first glance it appears, that the preamble need not be construed as limiting "amusement" to that of
"pet animals." In this instance, Patentee did not argue during prosecution that his invention was patentably distinct from Postings based on the fact that a pet was to be amused. Indeed, he could not have done so because the Postings reference in fact discloses a device for the exercising of a pet (a dog). However, the intended use specified in the preamble, and which the Patentee relied upon in the prosecution history, is that of a "toy device for the amusement of pet animals." Plaintiff has cited no authority for the proposition that a preamble specifying the intended use of the device should be dissected in the claim construction process to include only the single distinguishing element. Such a dissection would be particularly odd in this instance where the remaining phrase ("for the amusement") is simply not logically cognizable without reference to the "amusee."

In light of the foregoing analysis, the Court will construe the preamble phrase "a toy device for the amusement of pet animals" as "a device for the amusement of an animal kept for pleasure or companionship, rather than solely for utility." 1

--- Footnotes ---

1 Construction of the phrase "toy" is unnecessary as it would merely be redundant with the inclusion of "amusement."

--- End Footnotes ---

4206

2. The product claims -- "a tracer"

Inverness claims that the proper construction of the term "tracer" in claim 38 of the Campbell patent is "a tracer that is a separate component from (i.e., is not attached to) the solid support." Inverness's expert, Dr. Gunter, argues that this construction is suggested by the structure of claim 38, in which a semicolon separates the clause introducing the tracer from the clause explaining the solid support. Furthermore, Dr. Gunter notes that "kit" claims are typically understood to involve separate components. He cites Jeffrey G. Sheldon, How to Write a Patent Application, Practising Law Institute, New York City (December 1995), in support of his understanding of "kit claims." According to that publication, "many products are sold unassembled or contain a variety of parts that are used together. Kit claims are particularly valuable for those products." Based on these facts, Dr. Gunter alleges that the separate listing of the two components requires an interpretation of claim 38 that the tracer not be located on the solid support. Dr. Gunter believes that this is the proper construction of claim 38 because the patent specification never discloses a configuration in which the tracer is located on, or attached to, the solid support. He finds further support in the prosecution history of the Rosenstein patent, in which BD stated that Campbell does not disclose that the tracer can be placed on the solid support and be made to flow to the binder area, as is claimed in Rosenstein.

BD argues that the neither term "separate" nor "attached" is used in claim 38 to describe the relation between the tracer and the solid support, and thus the claim does not require any particular relation between those components of the invention. It also contests Inverness's assertion that the fact claim 38 is described as a "kit" claim provides support for the conclusion that the tracer and solid support must be separate components of the invention.

Beginning with the language of claim 38, Inverness's proposed construction is premised on the description of the claim as a "kit claim" and the use of a semicolon to divide the tracer clause from the solid support. Taking these points in order, Dr. Gunter's support for his hypothesis that "kit" claims must contain separate elements is the PLI publication by Jeffrey Sheldon. The PLI publication, however, is extrinsic evidence and thus should not be considered until the court has concluded, after considering the intrinsic evidence, that the claims remain ambiguous. 3 Second, the use of a semicolon in claim 38 is a grammatical tool for separating two independent clauses and does not necessarily indicate that the items on opposing sides of the semicolon must also be physically separated. Thus, the court finds that neither the description of the claim as a "kit," nor the use of a semicolon imparts a characterization of the physical relationship between the tracer and the solid support. Instead, the court finds that the plain meaning of the claim's use of only a semicolon to differentiate the tracer from the solid support is that claim 38 does not require any particular physical relationship between those components of the
assay.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

3 Even as extrinsic evidence, however, the PLI publication is of dubious value. It was published eight years after the Campbell patent was issued and thus cannot be said to be evidence of the meaning of terms at the time the patent was issued. See AI-Site Corp., 174 F.3d at 1320. Moreover, PLI publications are generally intended for lawyers, and thus it is unlikely that a person of skill in the art of immunoassays would be knowledgeable of the publication's contents or import. See Pall Corp. v. PTI Techs., Inc., 259 F.3d 1383, 1393 (Fed. Cir. 2001) ("In claim construction, a claim is interpreted from the perspective of one of ordinary skill in the art.").

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

Inverness's reliance on the specification of the Campbell patent and the prosecution history of the Rosenstein patent to support its construction of claim 38 is unhelpful for the same reasons this evidence does not support its argument on the construction of the process claims. While it is true that the patent specification reveals only the attachment of binder antibodies to the solid support and nowhere suggests that the tracer might also be attached, this fact does not require that the proper construction of claim 38 be limited to those immunoassays that keep the tracer and solid support separate. Once again, the patent specification cannot be used to limit a claim in a manner suggested only in the specification or preferred embodiment of the invention. Intervet Am., 887 F.2d at 1053. Neither can the prosecution history of a later patent such as Rosenstein, which is extrinsic evidence, alter the clear meaning of the terms in the claim of an earlier patent. See Interactive Gift Express, 256 F.3d at 1332. Thus, the court finds that neither the Campbell patent's specification nor the Rosenstein patent's prosecution history alters the clear meaning of claim 38. Claim 38 reveals the use of a tracer and a solid support including a binder as an immunoassay, but it does not require that the tracer and solid support have any particular physical relationship. Therefore, the court finds that Inverness's suggested interpretation of claim 38, that the claim requires a tracer separate from the solid support, is unsupported.

4207

WMA next argues that the Glide-Traks do not infringe on the '201 patent's claims of having "track means on said divider member comprising a pair of elongated rails." This claim element describes the characteristics of the '201's divider member that allow the pusher member (the part of the device that urges merchandise towards the front of the shelf) to engage and move along the divider member (in the direction perpendicular to the shelf's edge). WMA asks that we adopt the following definitions, all taken from the Random House dictionary, in construing this claim element:

"Track": 1. a structure consisting of a pair of parallel lines of rails with their crossties that provides a road for railroad trains.

"Pair": 1. two identical, similar, or corresponding things that are matched for use together: a pair of gloves.

"Rail[s]": 1. a bar of wood or metal fixed horizontally for any of various purposes, as for a support, barrier, fence, or railing.

WMA suggests that based on these definitions, along with language from the '201's specifications 4 and the patent's prosecution history, we should construe the claim element "track means on said divider comprising a pair of elongated rails" to mean "two parallel lines of bars that are mirror images of each other, used together and fixed horizontally for supporting and providing a path that constrains the motion of the pusher member." In asking that we accept this construction, WMA emphasizes the railroad-like nature of the track along which the '201's pusher member rides. WMA's offered construction is descriptive of the '201: the track on which the '201's pusher rides is comprised of two parallel, horizontal and relatively flat bars that are completely symmetrical to one another (while looking down the length of the divider member -- perpendicular to the shelf's edge). WMA contends that because the mechanisms by which the Glide-Traks' pusher members remain engaged in and slide down the divider members lack such symmetry, there is no infringement on this element of the '201 patent.
In spite of WMA's assertion that the mirror-image railroad analogy offers the best construction of the disputed claim element, Texas Digital mandates that we first look to determine whether the words "track," "rail," and "pair" have other ordinary meanings -- potentially broader than the ones propounded by WMA -- on which our construction analysis should begin. Random House, WMA's chosen dictionary, also defines "track" as: "7. a course or route followed" or "9. a path or course laid out for some particular purpose." Under these definitions, a "track" need not be of the type on which trains run, but could also encompass a more general path or route on which something could travel. In addition, WMA's own definition of "pair" allows for the paired items that are to be matched for use together to not only be "identical," but "similar or corresponding" as well. Furthermore, the '201's specifications speak of the divider member being comprised of "a track having side rails," but do not elaborate that the track or rails need be of the mirror-image nature found on railroad tracks. Nor can such a limitation be construed from a close review of the '201's prosecution history.

Following Texas Digital's mandate that "if more than one dictionary definition is consistent with the use of the words in the intrinsic record, the claim terms may be construed to encompass all such consistent meanings," 308 F.3d at 1203, we will adopt a more generalized construction for "track means on said divider comprising a pair of elongated rails": Two similar or corresponding plastic bars, 5 matched for use together, that run horizontally (in the direction perpendicular to the shelf's edge) with the purpose of guiding a pusher member down a fixed and defined path. This construction delineates the features of the '201's divider member that keep the pusher member in place as it moves merchandise down the shelf, but does not contain the railroad-like symmetry limitations that WMA asks us to read into the claim. Even if we had been able to ascertain such a limitation, the Federal Circuit's "proscription of not reading limitations from the specification into the claim," Texas Digital at 1205, supports our more expansive reading of the claim element at issue.

Even though the Random House definition of "rail" speaks of a "a bar of wood or metal," the '201 is made almost entirely of plastic. However, under the Webster's New Twentieth Century Dictionary (1983) -- also submitted by WMA -- a rail may be "a bar of wood, metal, etc." (emphasis added). This broadened definition of "rail" allows for a rail to be composed of materials other than wood or metal.

Claim 1 recites "a lace trained between the eyelets on the first and second eyelet strips." Similarly, claim 10 recites "a lace trained between the eyelets of the carrier strips." Plaintiff argues that this language means "a lace threaded in a way to connect the eyelet or eyelets on the first eyelet strip with the eyelet or eyelets on the second eyelet strip." However, because I have determined that the claim term "set of lace eyelets" requires each eyelet strip to carry two or more lace eyelets, I read plaintiff's proposed construction as requiring "a lace threaded in a way to connect the eyelets on the first eyelet strip with the eyelets on the second eyelet strip." Defendant contends that the claim language in question requires a construction "that tightening of the brace is achieved with a lace that goes back and forth through the eyelets on the first removable flap and the eyelets on the second removable flap to draw together the flaps." I conclude that plaintiff's proposed definition is the appropriate one. Courts should avoid the temptation to read functional limitations into claims that do not recite any. See, e.g., Rodime PLC v. Seagate Technology, Inc., 174 F.3d 1294, 1303 (Fed. Cir. 1999). This is precisely what defendant asks the court to do by proposing a construction that ascribes to the lace a specific function ("tightening" the brace) and the method for achieving that function ("going back and forth through the eyelets... to draw together the flaps"). Moreover, defendant's proposed construction reads the term "lace trained" as if "lace" were a verb, rather than a noun. But the verb
here is "trained," not "laced." The verb "to train" has several definition, many of which are irrelevant (for example, to "coach in or accustom to a mode of behavior or performance," or "to prepare physically, as with a regimen"). The only pertinent definitions of "trained" are "to cause . . . to take a designed course or shape, as by manipulating" and "to focus on or aim at . . . direct." The American Heritage Dictionary of the English Language at 1830. These definitions comport with plaintiff's proposed construction of the relevant phrases in claims 1 and 10 as "a lace threaded in a way to connect the eyelets on the first eyelet strip with the eyelets on the second eyelet strip." Accordingly, I will adopt plaintiff's proposed construction of this phrase.

4. "Transducer" Limitation

267. Claim 2 of the '904 patent recites "a transducer for generating said trigger signal." A "transducer" is known to those of ordinary skill in the art as a device that converts one form of energy, e.g., mechanical, into another form of energy, e.g., electrical. Dr. DeBra testified that the MIDA microswitch converts mechanical movement into an electrical signal, i.e., acts as a transducer and may be considered to be a transducer according to popular usage. Tr 1397-98, 1466. Because, however, of the very broad nature of the term "transducer," one of ordinary skill in the art would construe it to include only various transducers and switches capable of signaling as soon as possible after initial contact between the stylus and an object so as to conform with the disclosure and teachings of the patent. Tr 1397-98.

268. Marposs does not infringe claim 2 of the '904 patent. Claim 2 of the '904 patent requires a "transducer" for detecting the "instant of contact" between the stylus and an object. The MIDA microswitch cannot do this as set forth in detail above. Tr 1398. See PP 112-13, 130, 132-33 supra. Therefore, claim 2 is not infringed by any MIDA probe, for at least this reason.

7. "transferring"

Crane urges the court to refrain from construing the term, while the defendants propose a construction distinguishing between "transferring" and "carrying." In light of the claim language and the various embodiments, the court finds it necessary to specifically distinguish the terms.

The court defines "transferring" and "transferred" as "moving (or moved) through a distance."

5. Transferring Electrical Energy at a Predetermined Radio Frequency Range as Arcs in Ionized Conductive Pathways at a Predetermined Power Level Within the Gas Jet in an Electrical Circuit Which Includes the Tissue

The final disputed claim term "transferring electrical energy at a predetermined radio frequency range as arcs in ionized conductive pathways at a predetermined power level within the gas jet in an electrical circuit which includes the tissue" is found in Claim 10 as set forth above.

ConMed's Proposed Definition: Transferring electrical energy through an electrode within the nozzle or gas flow at a predetermined radio frequency by imparting an electrical charge to particles of the gas stream that allows the formation of the improved eschar.

Canady's Proposed Definition: A fulguration mode of operation.
Unlike the terms of Claim 1, this term at issue in Claim 10 is not a means plus function claim. Rather, I must give the terms their ordinary meaning as set forth under the standards above. I note from the Joint Disputed Claim Terms Chart that the terms ionized conductive pathways and gas jet are not in dispute.

14 According to the parties, "ionized conductive pathways" is construed as pathways which carry electrical current, as opposed to radiate current and "gas jet" is construed as a directed or substantially laminar flow stream. Docket No. 58, Ex. B. p. 3. Thus, I must seek to construe the other disputed claim terms.

The specification provides as follows:

The ESG 46 supplies electrical energy over a supply conductor 56 of the cord 48 to the pencil 42. The conductor 56 is electrically connected in the pencil to a needle-like electrode 58 which extends into the nozzle 52. The electrical energy supplied by the ESG 46 is of predetermined characteristic sufficient to ionize the gas flowing through the nozzle 52 and to create ionized pathways in the jet 54. The electrical energy travels in the ionized pathways in the jet 54 to a body tissue 62 where it creates a predetermined electrosurgical effect on the tissue 62.

In the fulguration mode of operation of the ESU, also referred to herein as a "macro" mode of operation, electrical energy is transferred in the ionized pathways in the form of arcs 60. The arcs 60 travel within the jet 54 until they reach the tissue 62 at the electrosurgical site. The jet 54 expands slightly above the surface of the tissue 62 and the arcs 60 disperse over a slightly enlarged area of the tissue surface compared to the cross-sectional area of the jet 54. The electrical energy of the arcs is transferred into the tissue 62 and creates the upper arc hole reticulum or layer 30 and a desiccated layer 32 therebelow.

Docket No. 58, Ex. A. col. 8, ll. 14-37. The specification also teaches that "electrical power at a predetermined level is delivered from the power supply 308 to an RF drive circuit 312. The logic control 304 delivers RF switching signals to the RF drive 312, thereby causing the RF drive 312 to selectively couple energy from the power supply 308 to a resonant output circuit 314 at a frequency established by the RF drive pluses. Energy is transferred from the resonant output circuit 314 to the pencil 42, and current is returned to the resonant output circuit 314 from the patient plate 70 (FIG. 4)." Id. at col. 15, ll. 26-40. Consequently, I construe the term to mean transferring electrical energy, at a predetermined radio frequency from the RF drive to a resonant output circuit to the pencil to the needle-like electrode, which extends into the nozzle, to the tissue as arcs in ionized conductive pathways in a gas jet.

ConMed argues that the term "means transferring electrical energy at a predetermined radio frequency range" found in the second means-plus-function clause of Claim 1 must have the same meaning as the disputed term "transferring electrical energy at a predetermined radio frequency range as arcs in ionized conductive pathways at a predetermined power level with the gas jet in an electrical circuit which includes the tissue" found in Claim 10. Docket No. 58, p. 19. I disagree. To begin with, Claim 1 is in a means-plus-function format and Claim 10 is not a means-plus-function format. Second, the claim term at issue in Claim 10 contains additional language, namely "as arcs in ionized conductive pathways at a predetermined power level with the gas jet in an electrical circuit which includes the tissue," which must be given its ordinary and customary meaning or defined by the intrinsic evidence. Consequently, I reject ConMed's argument in this regard.

In addition, I reject Canady's proposed definition. (Docket No. 66, p. 54). Canady's proposed definition fails to take into consideration the entirety of the claim term at issue as well. Id.

4212

F. Transferring Unit

Finally, Ken calls for means-plus-function treatment of the "transferring unit" referenced in apparatus claim 1 and system
At the beginning of the assembly line, through the claimed machine. Function treatment is denied. Instead, the transferring unit is interpreted as a mechanism that moves ribbon stock, from a roll.

The court finds that the transferring unit connotes structure, not function, to one skilled in the art. Accordingly, means-plus-function treatment is denied. Instead, the transferring unit is interpreted as a mechanism that moves ribbon stock, from a roll at the beginning of the assembly line, through the claimed machine. See Section 2.C., above.
19. said first location on said wall after said seaming operation forming the transition from said double seam to said second wall portion ('875 patent, claim 32)

Crown's proposed construction is "[t]he first location, after seaming, at which the double seam region changes to the second wall portion." 84 Rexam's proposed construction is "[t]he location on the end wall at the lowermost extent of the double seam." 85

The court adopts Crown's proposed construction.

At 15, above, the court construed the "first location on said wall" to mean "the point on the wall of the can end that becomes the lowermost extent of the double seam." Each parties' construction properly references the fact that the disputed claim term is directed at a can end after a double seam has been formed with a can body.

This claim term, and the claim term "said wall and said reinforcing bead forming a transition therebetween," of claim 50 of the '875 patent (23, below) are similar in that the parties disagree about how the word "transition" should be defined. Crown argues that the specification does not define the term "transition" and does not indicate that word has a specialized meaning and, therefore, that the plain meaning should apply. Crown contends that the plain meaning of "transition" is "a passage from one state, condition, or place to another: change." The court agrees that, in the context of the patents-in-suit, that defining "transition" to mean changing from one place to another is appropriate and Crown's proposed construction is consistent with the claim language. This is also consistent with Rexam's argument that "the plain meaning of the claim terms means that the 'first location' recited by claim 32 of the '875 patent is the point or place where the seam ends and the lower portion or 'second wall portion' begins." 86

Crown's proposed construction of "transition from said double seam to said second wall portion," taken together with the court's construction of "first location" as "the point on the wall of the can end that becomes the lowermost extent of the double seam" and the claim's recital that the "first and second locations form end points of said second wall portion" provides sufficient basis to identify the location of the transition.

The court, therefore, adopts Crown's proposed construction: "the first location, after seaming, at which the double seam region changes to the second wall portion."
The district court construed "translated forward" to mean "moved axially forward in the direction of the working medium." The district court found that one of ordinary skill in the art would have several years of experience designing fan blades with, most likely, an advanced engineering degree in fluid mechanics. The parties do not contest the district court's finding regarding the level of ordinary skill in the art.

The plain language of "translated forward" means moved toward the forward direction, but the claim language does not designate a clear "forward" direction. The district court found that one of ordinary skill in the art would necessarily have consulted the specification to learn the meaning of "translated forward." The district court also found no use of the term "translation" in the industry or in any prior art other than the related '985 patent.

As the claim language does not clearly state the directional tilt of the outer region, this court as well consults the specification. Based on that source, this court construes "translated forward" to mean "moved forward toward the axial direction." The specification discusses translation forward only with reference to the axial direction, which is parallel to the rotational axis of the fan and engine. The specification, referring to Figure 3, states:

The beneficial effect of the invention is appreciated primarily by reference to FIG. 3 . . . . [T]he nonincreasing character of the second sweep angle . . . according to the invention causes a portion of the airfoil leading edge to be far enough forward (upstream) in the working medium flow . . . . In addition, the passage shock 66 (which remains attached to the airfoil leading edge and therefore is translated forward along with the leading edge) is brought into coincidence with the endwall shock . . . .

The embodiment of FIGS. 2 and 3 illustrates a blade whose leading edge, in comparison to the leading edge of a conventional blade, has been translated axially forward parallel to the rotational axis . . . .

'931 application col.4 ll.33-66 (emphases added). As "forward," according to its plain language, must denote a specific direction, this court honors the applicant's choice to define that term with reference to the axial direction.

Figures 2 and 3 of the '931 application illustrate the support for this construction. Figure 2 is a cross sectional view of a swept back fan blade including an alternative leading edge profile shown by dotted lines and a prior art blade shown in phantom.

In Figure 2, the blade formed by solid lines (22) represents an embodiment of the invention. The blade with the dashed lines (22') within r[t-outer] to r[tip] represents a prior art blade. The alternative blade formed with dotted lines within r[t-inner] and r[t-outer] shows a different leading edge profile. The arrows (48), pointed in the direction of the airflow into the engine, indicate a direction opposite the forward axial direction. Translation forward in the axial direction requires moving the leading edge of the blade directly to the left. In Figure 2, the blade with the dashed lines (22') is moved to the left in the region between r[t-outer] to r[tip] to form the blade of the invention shown as a solid line (22). Thus, the blade of the invention (22), from r[t-outer] to r[tip], is translated forward (in the axial direction) in comparison with the the prior art blade (22').

Figure 3 is a developed view taken along the line 3-3 of Figure 2 illustrating the tips of four blades along with four prior art blades shown in phantom.

In Figure 3, the blade formed by solid lines (22) represents an embodiment of the invention. The blade with the dashed lines (22') represents a prior art blade. The arrows (48) point in the direction of the airflow into the engine and also point away from the forward axial direction. Translation forward in the axial direction requires moving the leading edge of the blade directly to the left. In Figure 3, the blade with the dashed lines (22') is moved to the left to form the blade of the invention shown as a solid line (22). Thus, the invention translates or moves the blade (22) forward in the axial direction from the prior art blade (22').

UTC argues that "translated forward" in the '931 application means "moved forward toward the direction of the relative
velocity vector." UTC contends that movement in any direction--axial or circumferential--is movement toward the relative velocity vector. Under UTC's proposed construction, either purely circumferential or purely axial movements are encompassed by the term "translated forward." The axial and circumferential directions are at ninety degree angles to each other. Thus, this court perceives that a construction of "translated forward" that includes both the circumferential and axial directions, at right angles to each other, would unreasonably broaden this claim limitation.

Figure 5 of the '931 application shows movement of the outer region in the circumferential direction.

[SEE FIG. 5 IN ORIGINAL]

In Figure 5, the blade formed by solid lines (22) represents an embodiment of the '931 application. The blade with the dashed lines (22') represents a prior art blade. The arrow (R) is pointed in the circumferential direction. Translation forward in the axial direction would require the prior art blade (22') be moved to the left to form the blade (22). As shown by Figure 5, the prior art blade (22') is moved up, not to the left, to form the blade (22). Thus, under this court's claim construction, the blade (22) in Figure 5 is not translated forward in the axial direction.

Although Figure 5 of the '931 application shows movement of the outer region in the circumferential direction, the specification does not support UTC's proposed construction. The specification does not use "translated forward" to describe the embodiment in Figure 5. Instead, the specification describes the movement in Figure 5 as "displaced circumferentially." '931 application col.5 ll.4-12. This court's construction of "translated forward" ("moved forward toward the axial direction") excludes the embodiment in Figure 5. Although reluctant to exclude an embodiment, this court must not allow the disclosed embodiment to "outweigh the language of the claim, especially when the court's construction is supported by the intrinsic evidence." See TIP Sys., LLC v. Phillips & Brooks/Gladwin, Inc., 529 F.3d 1364, 1373 (Fed. Cir. 2008). In this case, this court cannot allow the claim to encompass both the embodiment in Figures 1 through 3 (with movement toward the axial direction) and the embodiment in Figure 5 (with movement toward the circumferential direction). A claim construction that embraced both alternative embodiments would be unreasonable because the single claimed direction "forward" would then encompass two directions at right angles to each other.

UTC argues that the specification of the '931 application supports its construction because it states that "the invention contemplates any blade whose airfoil intercepts the endwall shock to bring the passage shock into coincidence with the endwall shock." '931 application col.5 ll.2-4. This argument overlooks the language of the claim that specifies the translational direction for the blade. According to the claim, the blade must be "translated forward." '931 application claim 23. This court considers unreasonable an interpretation that allows that term to cover two directions at right angles to each other. Thus, interpreting the claim to encompass translation in any direction that causes the airfoil of the fan blade to intercept the endwall shock would unreasonably broaden "translated forward." Moreover, this court notes that the claim reference to intercepting the endwall shock appears after the claim specifies forward translation. In that context, the interception reference merely describes a benefit derived from forward translation, rather than changing the meaning of "forward" to embrace more than a single direction.

UTC argues that the prosecution history of the related '040 patent shows that "translated forward" means "moved forward toward the direction of the relative velocity vector." The portion of the prosecution history of the '040 patent serving as a basis for UTC's argument states:

The applicants' specification uses the term "translated" in the exact same context in which the claims use it to recite a blade feature in accordance with this aspect of the invention. See, for example, page 4, line 65, and Figures 2 and 5 of the present application.

J.A. 7251. This inference from the prosecution history does not persuade this court because the specification of the '931 application clearly excludes this construction. Moreover, the prosecution history of the '040 patent does not favor one construction over the other. This argument to the examiner of the related '040 patent only describes the use of "translated," not "translated forward." The important issue in this claim construction is the direction of the translation, not the mere fact of some translation. Explaining the term "translated" in isolation does not guide this court's construction of "translated forward." Also, this prosecution history passage is unclear. A suggestion that the specification uses a term "in the exact same context" as the claims is vague. Indeed that explanation does not assist this court in determining the direction of "forward." In sum, this court declines to unreasonably broaden a specific claim term based on questionable prosecution history when
the specification requires a particular construction.

A. "Translucent Housing"

1. Claim Construction Redux

Taylor argues that "translucent housing" is properly construed as a "housing having a translucent portion." DCAG argues that "translucent housing" means a housing that is entirely translucent. Because it was not identified for construction in the Markman proceeding, the Court must now construe the term as a matter of law before conducting an infringement analysis.

First, the exact meaning of "housing" must be determined. Claim 1 requires "a translucent housing (12) including a plastic shell being substantially cup shaped and having an open end and a closed end and a wall extending from said closed end." The wall, or, the forward facing portion of the housing, contains and conceals the illuminating image forming means, which is mounted within the housing. The mirror means is "retained by" the housing at the open end. Hence, "housing" is simply defined by the function it performs. The housing is a structure that contains the illuminating image forming means inside it and connects to the mirror mechanism at the open end.

The next issue is whether "translucent" 8 refers to the entire housing or to only a portion of the housing. The first step, obviously, is to look at the plain language of the claim itself. Vitronics, 90 F.3d at 1582 (words in a claim are "generally given their ordinary and customary meaning" unless the specification or prosecution history clearly show that some other meaning is intended). "Housing" is directly modified by the adjective "translucent." The ordinary reading when such language is used is that the entire structure must possess the stated quality. See Saeilo, Inc. v. Colts Mfg, Co., 26 Fed. Appx. 966, 970 (Fed. Cir. 2002) (unpublished) ("The claim language requires only that the 'lug' be laterally offset from the bore axis. Between 'the entire lug' and 'a portion of the lug,' we think the former is the more natural reading of the plain term 'lug.' When language is used precisely and naturally, a piece or portion of a lug is not a 'lug.'"); Nat'l Recovery Techs., Inc. v. Magnetic Separation Sys., Inc., 166 F.3d 1190, 1195 (Fed. Cir. 1999) ("Claim 1 clearly indicates that the 'special quality' for which a signal is selected is whether or not that signal has passed through an irregularity. There is no indication in the plain meaning of the limitation, or from the claim as a whole, that this selection criterion is to apply only some of the time.").

Modifying adjectives are certainly added for a reason. See Johnson Worldwide Assocs, v. Zebeo Corp., 175 F.3d 985, 989 (Fed. Cir. 1999) ("General descriptive terms will ordinarily be given their full meaning; modifiers will not be added to broad terms standing alone.").

8 The surface of an object can be transparent, translucent, or opaque. These terms mean the following:

transparent: Having the property of transmitting light, so as to render bodies lying beyond completely visible; that can be seen through.

translucent: Allowing the passage of light, yet diffusing it so as not to render bodies lying beyond clearly visible; semi-transparent.

opaque: Impermeable to light, not transmitting light, not transparent; hence, impenetrable to sight.

Claim 1 could have been drafted to require a "partially translucent" housing or simply a "housing" with a wall that is at least partially translucent. See Saeilo, 26 Fed. Appx. at 970. However, claim 1 as originally drafted and as allowed directly refers to the mirror assembly's housing as translucent. See Sage Prods., Inc. v. Devon Indus., Inc., 126 F.3d 1420, 1425 (Fed. Cir. 1997) ("As between the patentee who had a clear opportunity to negotiate broader claims but did not do so, and the public at large, it is the patentee who must bear the cost of its failure to seek protection for this foreseeable alteration of its claimed structure.").

Moreover, the housing might not be able to perform its function if it was not completely translucent. Claim 1 specifies that the housing includes a wall that contains and conceals the illuminating image forming means at the closed end. If part of the housing were transparent, for instance, incident light could pass through and the illuminating image forming means would not be concealed.

Taylor argues that DCAG's construction improperly reads in a limitation of "completely translucent" from outside the claim, which is not supported by the specification or the prosecution history. Taylor points to the following language in the specification: "The present invention provides a mirror assembly including a housing having a translucent portion, mirror means retained by the housing, and illuminating image forming means mounted within the housing and behind the mirror for projecting an image through the translucent portion." '019 patent, col. 1, II. 50-55 (emphasis added). The Abstract also states that the mirror assembly includes a housing "having a translucent portion." Id., Abstract (emphasis added). However, the specification also describes the drawings as follows: "The assembly 10 includes a translucent housing generally indicated at 12. The housing is constructed from a translucent material, such as a hard plastic." Id., col. 2, II. 8-10.

Just as it is improper to read in a limitation from outside the claims of a patent, it is improper to read an express limitation out of a claim "because 'courts can neither broaden nor narrow claims to give the patentee something different than what he has set forth.'" Texas Instruments v. United States ITC, 988 F.2d 1165, 1171 (Fed. Cir. 1993) (citing Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 396 (Ct. Cl. 1967)). Interpreting a "translucent housing" to mean a "partially translucent housing" would effectively read out the "translucent" limitation from claim 1.

The prosecution history 9 of the '019 patent supports this interpretation and fairly read establishes that the claim language and specification are not conflicting. Claim 1 as filed read (emphasis added):

1. A mirror assembly (10) comprising: a translucent housing (12) having a translucent portion; mirror means (20) retained by said housing (12); and illuminating image forming means (26) mounted within said housing (12) and behind said mirror means (20) for projecting an image through said translucent portion of said housing (12).

The claim was initially rejected under 35 U.S.C. § 103 as being unpatentable over Dawe (Great Britain Patent No. 271,917) in view of Costello (U.S. Patent No. 1,608,548) or Marshall (U.S. Patent No. 1,954,740). Dawe covers a mirror assembly with an opaque screen at the front end. Parts of the screen are cut out into "portions wholly or partly translucent to provide indicating marks for a plurality of indications." Dawe, col. 1, II. 24-26. Behind the screen are individually partitioned lamps for projecting an image through the cut out parts of the screen. Id., col. 1, II. 26-43. In the preferred embodiment, a glass cover is placed in front of the screen. Id., col. 2, II. 76-78. Figure 2 of Dawe is a front view of the device showing the cut out opaque screen and partitioned light sources:

[SEE Fig.2. IN ORIGINAL]

Rejecting claim 1, the examiner stated:

It would have been obvious to one having ordinary skill in the art to substitute a translucent outer housing plate and stencil-type image projecting means as shown by Costello or Marshall for the screen 9 and cover 10 of Dawe. The well known signs of Costello and Marshall have an equivalent display function to the screen of Dawe.
It would have been an obvious design choice to one of ordinary skill in the art to form the housing of Dawe as an integral translucent housing or shell. The use of smoke tinted translucent material would have been an obvious design choice to one of ordinary skill.

9 The Decision on Claim Construction at 7-13 also contains a discussion of the '019 patent's prosecution history.

On May 2, 1988, an Amendment Under 116 was filed but not entered. It required "translucent housing means … having a continuous and uninterrupted translucent portion."

The applicant filed an amendment on June 21, 1988 that, among other changes, deleted "having a translucent portion."

Claim 1 was amended to read (additions underlined, deleted elements in brackets):

1. A mirror assembly (10) comprising:

   a translucent housing (12) including a plastic shell being substantially cup shaped and having an open end and a closed end and a wall extending from said closed end.

   said wall and said closed end appearing opaque and containing and concealing illuminating image forming means within said housing (12) and preventing incident light from passing therethrough while only revealing an illuminated image through at least one of said wall and closed end projected from the illuminating image forming means [having a translucent portion];

   mirror means (20) retained by said housing (12) within and adjacent to said open end; and

   illuminating image means (26) mounted within said housing (12) adjacent at least one of said closed end portion and wall portion and completely behind said mirror means (20) so as to be hidden from view from outside said housing (12) and mirror means (20) for projecting only an illuminated image through at least one of said wall and closed end portion [said translucent portion] of said shell [housing] (12) while the remainder of said illuminating image forming means (26) is hidden within said housing (12).

The applicant stated that claim 1 was amended "to further characterize the invention and more specifically distinguish the invention over the cited prior art." Specifically, the applicant argued that the mirror assembly in claim 1 provides "a clear illuminated image through a translucent shell housing while not illuminating the remainder of the housing" and distinguished Dawe because it uses a stencil and "does not relate to the problem of projecting an image through a dark housing while keeping the remainder of the housing dark."

In a later Office Action rejecting the applicant's claims for indefiniteness, the examiner stated that "claim 1, lines 2-3 already recite that the housing including the shell is translucent."

"The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995). The Court must "assess whether a patentee relinquished a particular claim construction based on the totality of the prosecution history, which includes amendments to claims and arguments made to overcome or distinguish references." Rheox, Inc, v. Entact. Inc., 276 F.3d 1319, 1326 (Fed. Cir. 2002). Taylor cites two instances where the applicant referenced a "translucent portion" in the June 21, 1988 amendment. 10

10 See June 21, 1988 Preliminary Amendment, at 4 ("project only an illuminated image through the translucent portion of the shell of the housing"), 8 ("projects only an illuminated image to the translucent portion of the shell of the housing").
Exchanging the totality of the prosecution history, it is clear that claim 1 does not encompass a housing that is only partially translucent. It is undisputed that the examiner rejected Taylor's claim with a "translucent portion" but allowed the claim with more detailed and narrow language. Moreover, Taylor expressly disclaimed a mirror assembly with "a housing having a central longitudinal portion of a transparent or translucent element and a light source within the housing." '019 patent, col. 1, ll. 35-37 (citing U.S. Patent No. 2,595,331 to Calihan et al.); see December 16, 1987 Amendment, at 4 ("The Costello patent does not disclose a translucent housing but rather a lens mounted on a light assembly."); SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001) ("Where the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question."). "Translucent housing" has been consistently used to refer to a housing that is completely translucent. "A patentee may not proffer an interpretation for the purposes of litigation that would alter the indisputable public record consisting of the claims, the specification and the prosecution history, and treat the claims as a 'nose of wax.'" Southwall, 54 F.3d at 1578 (citation omitted).

The first element of the claim which is in dispute is the "transmission" element.

[A] transmission selectively connected to said engine output shaft, said transmission having several selectively actuated speed ratios, said transmission having a transmission output shaft, said selected speed ratios controlling the ratio of the input speed from said engine output shaft to the output speed of said transmission output shaft[.]

Exhibit A, supra, col.7 II.41-47. Eaton argues that the transmission of the invention is of necessity a manual one. Meritor states that the specification of the patent discloses that "[t]he transmission may be of any type known in the art." Id. col.3 II.15-16. However, this statement is followed by the further specification that, "[a] manual stick shift is operable to shift the transmission between any one of several speed ratios." Id. col.3 II.17-18. The use of a "manual stick shift" would be required with a manual transmission. Although not dispositive, the background of the patent discloses "[a] manual transmission typically slides toothed members relative to different gears to engage one of the gears. . . . To this end, vehicles with manual transmissions are equipped with clutches." Id. col.1 II.15-16, 33-34. And, in its answers to requests for admissions, Meritor admitted that "the intended purpose of the invention disclosed in the '477 patent is to enable the driver of a manual transmission vehicle to shift an engaged gear into neutral without need to use the clutch." Exhibit P, Meritor's Response to Eaton's Requests for Admission, attached to Defendant's Motion, at 4 (emphasis added).

The Board also interpreted this element. "Based on the specification of both parties' involved application or patent, the intended purpose of the invention as defined by the [claim] is to enable the driver of a manual transmission vehicle to shift an engaged gear into neutral without need to use the clutch." Exhibit D, Decision on Priority, Patent Interference No. 104,835, attached to Defendant's Motion, at 6 (emphasis added). "If actual zero torque at the flywheel is achieved, a driver may shift a manually operated transmission from an engaged gear into neutral without need to activate a clutch." Id. (bolding added). On numerous occasions in this litigation, Meritor represented that the claim construction provided by the Board should control, whether or not Meritor agreed therewith. The Court, therefore, concludes that the claim language of the patent claims a manual transmission.

As would be expected in a patent case, a determination that the invention is limited to a manual transmission does not completely resolve the issue. The parties also dispute the meaning of a "manual transmission." Meritor argues that any transmission which requires the driver to make a selection of gear by use of his or her body is a manual one. Eaton notes that a manual transmission is one which requires the operator to make the actual gear shift.

There are two types of transmissions commonly used in automotive applications; the manual transmission and the automatic transmission. Both transmissions require a device to disconnect the engine from the driveline when the vehicle is brought to a stop, or else the engine will stall. In a conventional manual transmission the device is the main clutch. In a conventional automatic transmission the device is a torque converter.
The words "manual" and "automatic" are also sometimes used to describe the process used to implement a gear shift. In this context the word manual implies that the driver must take some action to cause the shift to occur, for instance by moving a lever or pushing a button, and automatic (or automated) implies that the transmission will shift itself at the appropriate time.

Exhibit Q, Expert Report of Craig J. Hoff, Ph.D., attached to Defendant's Motion, filed under seal, at 7-8 (emphasis added).

This description of a manual transmission, made by Meritor's expert, Dr. Hoff, uses virtually identical language to that contained in the patent. For example, the abstract of the patent describes the invention as providing an alternative to using the clutch, while envisioning that the vehicle would also be equipped and used with a clutch. Exhibit A, supra, at "Abstract" ("An operator of a vehicle may request torque reduction on the connection between a transmission and an engine, or may use a clutch."). "A switch is provided to send a torque elimination request." Id. Obviously, this request is sent by the operator of the vehicle: "said engine control including an operator input to allow an operator to signal a desire to eliminate torque between said engine output shaft and said transmission output shaft[]." Id. col.7 II.49-52. And, the language of the patent describes a manual transmission versus the description of an automatic transmission provided by Meritor's own expert: "automatic (or automated) implies that the transmission will shift itself at the appropriate time." Exhibit Q, supra.

[I]t is an object of this invention to allow an operator to shift the transmission to a new speed without operating the clutch. To achieve the ability to shift the gear without clutching, the present invention incorporates a switch on the shift knob. . . . When an operator actuates [the] switch, a signal is sent to [the engine] requesting a zero torque load on the connection between the engine and transmission. . . . [T]he operator is able to request the torque elimination function.

Exhibit A, col.3 II.62-66; col.4 II.3-5, 10-11 (emphasis added).

The fact that Meritor's own expert limited the invention to a manual transmission is obvious from a complete reading of his expert report. Hoff explains the differences between a manual and automatic transmission as including different types of gears used in manual versus automatic transmissions.

There are two distinct steps in shifting to another gear in a manual gearbox [transmission]. The first step is to move the transmission from in-gear to neutral. The second step is to synchronize the speeds of the two halves of the transmission (input side and output side) so that the transmission can be engaged in the new gear. If there is a large torque being transmitted though the dog clutch [in the manual transmission], there will be significant friction developed between the dog teeth and it will be impossible to move the dog clutch out of engagement. This condition is referred to as "torque lock." In order to disengage the dog teeth it is necessary to remove the torque from the driveline. Conventionally, this is done by depressing the clutch pedal and breaking the connection between the engine and the transmission. Once the connection is broken the engine speed is controlled to match the appropriate speed of the transmission output shaft in the new gear. This allows the dog clutch to be moved into contact with the new gear.

The shifting process in an automatic gearbox is different and much more complex. The most important difference is that an automatic gearbox can be shifted with power being transmitted through the gearbox. This is sometimes referred to as "continuous power" shifting. This is possible because of the nature of planetary gears and the clutches used to control them.

There are advantages and disadvantages to each type of transmission. Compared to automatic gearboxes, manual gearboxes are more efficient, less costly, lighter, and more durable. Hence manual transmissions are desirable to the trucking industry. The main advantages of automatic transmissions are convenience for the driver and the ability to do continuous power shifting, which results in a smoother feeling shift. Hence automatic transmissions are desirable in the U.S. passenger car industry. Automated manual transmissions have the potential to combine the advantages of the manual gearbox with the convenience of automated shifting. 11

Exhibit Q, supra, at 9-10 (footnote added).
It is telling that Dr. Hoff did not describe the invention as relating to an automated manual transmission but only to a manual transmission.

By comparison, the specifications of the patent read:

A manual stick shift is operable to shift the transmission between any one of several speed ratios. Transmission includes a gear which is driven by the output of the engine when the clutch is closed. Gear engages and drives a pair of gears each mounted on a countershaft. . . . Gears engage and rotate a plurality of gears that are mounted to freely rotate on a main output shaft. A shift yoke slides a shift collar as directed by the vehicle operator to change the speed ratio of the transmission. . . . Collar also has external teeth that are selectively received within an inner peripheral bore on a gear. When the shift collar is in the position shown, . . . the teeth engage the gear such that the gear rotates the collar, and hence the shaft.

In moving the collar to shift to another speed ratio, the initial step is to move the teeth out of engagement from the inner peripheral bore of the gear. When the drive train is transmitting rotation to the shaft through the arrangement, . . . however, there is a high torque load on the connection between the teeth and the gear and between collar and shaft. This high torque load makes it difficult, if not impossible, for an individual to manually slide the collar relative to the gear. For this reason, vehicles have traditionally incorporated a clutch. An operator who wishes to shift a transmission to a new speed, initially actuates the clutch. This breaks the torque transmission discussed above, and allows the operator to disengage the transmission and move to neutral.

Exhibit A, supra, col.3 II.17-61 (emphasis added). This description, which repeatedly refers to the action of the driver as causing the gear shift, clearly describes a manual transmission. See, e.g., Marshall Brain, "How Manual Transmissions Work," available at http://www.howstuffworks.com/transmission.htm. 12 "[T]here are two big differences between an automatic transmission and a manual transmission: There is no clutch pedal in an automatic transmission [vehicle]. There is no gear shift in an automatic transmission [vehicle]. Once you put the transmission into drive, everything else is automatic." Karim Nice, "How Automatic Transmissions Work," available at http://www.howstuffworks.com/transmission.htm. Again, this is virtually identical to Dr. Hoff's description of an automated transmission: "automatic (or automated) implies that the transmission will shift itself at the appropriate time." Exhibit Q, supra, at 8.

In addition to the fact that the transmission described in the patent is identical to Dr. Hoff's definition of a manual transmission, he also opines that the '477 patent "can be applied to any transmission subject to 'torque lock.'" Id. at 10. In an automatic or automated manual transmission, the torque converter eliminates torque so that the transmission is not subject to torque lock. Nice, "How Automatic Transmissions Work," supra.

Finally, Dr. Hoff makes the following conclusions about the '477 patent:

Claim 1 does not say that it applies to a "manual transmission." In fact, . . . the patent specifications [state] that the "transmission may be of any type known in the art." However, the patent is particularly applicable to manual transmissions. . . . The requirement of breaking the "torque lock" by "actuating the clutch" is a necessary step in shifting a conventional manual gearbox. . . . The shift process described by [the patent] is initiated by an "operator input." This input occurs "when an operator actuates [a] switch." Consequently, the transmission that [the patent] describe[s] has the two key features of a manual transmission; a Manual Gearbox (i.e., a gearbox susceptible to torque lock . . .) and a Manual Shift (i.e., a shift in response to a drivers' input . . .).
In developing this opinion, I have taken "transmission" to mean "manual transmission" and I have applied the definition of "manual transmission" as it is commonly used in the automotive industry. Eaton's interpretation that "manual transmission" means "a transmission in which the driver's energy causes the disengagement and engagement of the gears" is not a commonly used definition in the automotive industry. 13

Exhibit Q, supra, at 18-19 (footnote and emphasis added) (citations omitted).

13 Despite this observation by Dr. Hoff, Eaton's position is identical to his position: "automatic (or automated) implies that the transmission will shift itself at the appropriate time" as opposed to a transmission in which the driver's energy causes the disengagement and engagement of gears.

Regardless of the position attributed to Eaton by Dr. Hoff, it is clear that he considered the transmission described in the patent to be a manual transmission. Mass. Inst. of Tech. & Elec. for Imaging, Inc. v. Abacus Software, 462 F.3d 1344, 1353 (Fed. Cir. 2006) (construing court has an "obligation to give the words of a claim 'their ordinary and customary meaning, [which] . . . is the meaning that the [words] would have to a person of ordinary skill in the art in question at the time of the invention" (quoting Phillips v. AWH Corp., 415 F.3d 1303, 1312-13 (Fed. Cir. 2005))). The Court recognizes that the claim language does not limit the transmission to a manual one by using the word "manual" in the actual claim. See, e.g., SuperGuide, 358 F.3d at 878 ("The claim language does not limit the disputed phrases to any particular type of technology or specify a particular type of signal format, such as analog or digital."). However, the claim does clearly define a method of eliminating "torque between said engine output shaft and said transmission output shaft, said operator signal requesting said engine control determine a zero torque parameter value[.]") Exhibit A, supra, col.7 II.50-53. This description is different than an automated transmission in which the transmission will shift itself at the appropriate time without a request from the operator. Thus, the Court is not adding the modifier "manual" to the claim; the language of the claim describes a transmission which is, of necessity, manual. "Unless there is an express intent to impart a novel meaning to the claim terms, the words of the claim are presumed to take on the ordinary and customary meanings attributed to them by those of ordinary skill in the art." Mars, Inc. v. H. J. Heinz Co., L.P., 377 F.3d 1369, 1373 (Fed. Cir. 2004) (quoting Int'l Rectifier Corp. v. IXYS Corp., 361 F.3d 1363, 1369 (Fed. Cir. 2004)). And, Meritor's own expert described the transmission as manual, both by operation and nomenclature. Id.; SuperGuide, 358 F.3d at 874 ("There is a 'heavy presumption' that the terms used in claims 'mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art.'" (quoting Tex. Digital, supra, at 1202)). Neither party disputes that Dr. Hoff is a person skilled in the art. "Importantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." Cook Biotech, Inc. v. Acell, Inc., 460 F.3d 1365, 1373 (Fed. Cir. 2006) (quoting Pfizer, Inc. v. Teva Pharms, USA, Inc., 429 F.3d 1364, 1372-73 (Fed. Cir. 2005)); accord, Phillips v. AWH Corp., supra; Application of Nelson, 280 F.2d 172, 181, 47 C.C.P.A. 1031, 1960 Dec. Comm'r Pat. 369 (C.C.P.A. 1960) ("The descriptions in patents are not addressed to the public generally, to lawyers or to judges, but, as section 112 says, to those skilled in the art to which the invention pertains or with which it is most nearly connected.").

And, as noted infra, the specification of the claim refers only to a manual transmission which is shifted into gear manually. "[T]he specification . . . [u]sually, . . . is dispositive; it is the single best guide to the meaning of a disputed term." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996).

Th[e] two paragraphs of section 112 frame the issue of claim interpretation for [the Court]. The second paragraph requires [the construing court] to look to the language of the claims to determine what "the applicant regards as his invention." On the other hand, the first paragraph requires that the specification describe the invention set forth in the claims. [The Federal Circuit has recently explained] the extent to which [a construing court] should resort to and rely on a patent's specification in seeking to ascertain the proper scope of its claims.
Ultimately, the interpretation to be given a term can only be determined and confirmed with a full understanding of what the inventors actually invented and intended to envelop with the claim. The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction.

... It is therefore entirely appropriate for a court, when conducting claim construction, to rely heavily on the written description for guidance as to the meaning of the claims. 

... Assigning . . . a limited role to the specification, and in particular requiring that any definition of claim language in the specification be express, is inconsistent with [the Federal Circuit's] rulings that the specification is "the single best guide to the meaning of a disputed term," and that the specification "acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication."

Phillips, 415 F.3d at 1312, 1316, 1317, 1320-21 (quoting Vitronics, supra) (footnote added; other citations omitted). Such is the case here: both Dr. Hoff and the patent specification describe a "manual" transmission.

--- Footnotes ---

14 Title 35 U.S.C. § 112 states that the specification "shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains . . . to make and use the same . . . ." The second paragraph of the section provides that the specification "shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention."

--- End Footnotes ---

Nor is this a case involving technology which had not yet been invented at the time of the patent, as was the case in SuperGuide, supra. Here, it is clear that at the time of the patent, automatic transmissions were included in the state of the art. However, manual transmissions were, according to Meritor's expert, preferable in the heavy trucking industry.

The element "transmission" in Claim 1 is thus construed to mean a manual transmission as described infra. It is not an automatic or automated transmission. Furthermore, it is noted that the above extensive discussion is also dispositive of other claim construction issues which are addressed below.

GO BACK

4217

Transmission

The parties agree and the Court finds that the word "means" as used in claim 7 is used to connote structure rather than function and therefore does not invoke the requirements of 35 U.S.C. § 112, P 6.

The dispute about this term centers on whether a transmission is an assembly of gears or more broadly something that transmits power from one element to another. The Court finds that neither definition is the plain meaning of the term. Some evidence regarding the meaning of this term appears in the intrinsic evidence, but it is not clear enough to be dispositive on the question of whether gears are required. For example, claim 14 refers to a "transmission geared to a reversible electric motor," and the specification refers to "[a] transmission gear assembly" which is connected to an electric motor. '822 Patent, at col.18, 1.47-48, col.4, 1.12-16. However, other claims mention a transmission but make no mention of gears. See, e.g., Id. at col.7, 1.13-14.

Finding no answer in the intrinsic evidence, the Court has consulted several dictionaries as an aid to determining the plain
meaning of the word. A typical definition of "transmission" is: "4.a. transference of force between machines or mechanisms, often with changes of torque and speed. b. a compact, enclosed unit of gears or the like for this purpose, as in an automobile." Random House Webster's Unabridged Dictionary 2011 (2d ed. 1997). The first definition above refers to a process, while the second definition refers to a device designed to carry out the process. Throughout the patent, each time the term "transmission" is used, it is clearly used in a sense which refers to a device, as opposed to the more abstract sense that refers to a process. See, e.g., '822 Patent, at col.4 1.16-17 ("The transmission 35 is bolted onto a horizontal support plate . . . ."). The plain meaning of the term, therefore, is best represented by the second definition.

4218

Plaintiff moves for an order construing the meaning of the term "transmission lines" as used in United States Patent No. 5,129,654 (the "Patent"), a patent for an electronic game apparatus, in particular a chessboard and pieces. No opposition papers have been filed because the attorneys for TASC BV ("TASC") were relieved of their representation in view of irreconcilable disagreements with their counsel after the motion was filed, and, although defendant TASC had notice of this motion, no attorneys have entered an appearance in their stead, despite the fact that this case is scheduled for trial on October 27, 1997.

Patent claims are to be construed by the court based first on the intrinsic evidence alone, i.e., the patent claims, the specification and the file history. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83 (Fed. Cir. 1996); see generally Markman v. Westview Instruments, Inc., 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996) (describing the history of patent construction).

The patent in suit contains a total of twenty claims, three of which are independent claims (1, 18 and 19) and the remainder are dependent claims. The scope of each of the claims is to be construed so as to differentiate it from any other claim. See United States v. Telectronics, Inc., 857 F.2d 778, 783-84 (Fed. Cir. 1988). Furthermore, it is improper to construe a claim by reading "into an independent claim a limitation explicitly set forth in another claim." Environmental Designs, Ltd. v. Union Oil Co. of Cal., 713 F.2d 693, 699 (Fed. Cir. 1983).

Plaintiff claims that defendant TASC's switchboard, an electronic chessboard, infringes independent claim 1 and dependent claim 11. At issue is whether the term "transmission lines" is limited to a structure which terminates in a characteristic matching resistance, a requirement of claim 15 which is dependent on claim 1. Under the doctrine of "claim differentiations" it is improper to interpret the term "transmission lines" in claims 1 and 11 in a way as to make them identical in scope to claim 15. See id. Accordingly, the requirement in claim 15 that "transmission lines are terminated in their characteristic impedance" cannot be read into claims 1 or 11 in which that language does not appear. Thus, "transmission lines" as used in claims 1 and 11 must be construed as encompassing electromagnetic energy conductive elements other than those which terminate in their characteristic impedance.

The Patent's specifications are consistent with this interpretation of "transmission lines" since those specifications define "transmission lines" as "an arrangement of conductive elements (in this case wires) capable of guiding an electromagnetic wave in a prescribed fashion with relatively small loss of signal strength." (Patent, Col. 6, lines 11-15.) That definition does not require the conductive elements (or wires) to be terminated in their characteristic impedance.

Nor do the specifications state that to accomplish the functions of chess piece location and piece recognition performed by the transmission lines, it is a necessary element of plaintiff's patented chessboard for the transmission lines to terminate in a characteristic matching resistance. The specifications disclose that its preferred two wire form is utilized primarily to take advantage of the basic high isolation between orthogonally arranged sets of two-wire transmission lines and the effectiveness of transferring energy from one two-wire transmission line to an orthogonal transmission line in the presence of a playing piece containing a resonant circuit, (Patent, Col. 8, lines 25-31); and that although the preferred form of the patent utilizes terminations for the two-wire transmissions lines of a characteristic impedance to inhibit any energy incident on the termination from being reflected back to the source "any such reflection would have a negligible effect on the identification process." (Patent, Col. 11, lines 49-59.)

The Patent's use of matching terminal resistance for transmission lines is described throughout the specifications as a preferred or best mode element of the invention not as an essential element of the Patent, e.g., Col. 6, Line 41 - Col. 7, line
5; Col. 8, Lines 1-6 (transmission lines "preferably" of the two-wire type with a termination); Col. 8, Lines 15-18 (termination of the termination line "could be" a resistor with a value which matches the characteristic impedance); Col. 11, Lines 53-56 (terminations 46 "can be" resistors of value Z).

The prosecution history is consistent with this interpretation. In his amended filing the applicant described the transmission lines as "preferably" a pair of balanced two-wire elements that are matched in their characteristic impedance. Cf. Declaration of Richard G. Berkley dated August 8, 1997, Exh. 3 at p. 4.

Accordingly, the term "transmission lines" as used in the Patent means an arrangement of conductive elements (wires) capable of conducting electric magnetic energy in a prescribed fashion over the extent of a chessboard which does not require termination of the arrangement in its characteristic matching impedance.

IT IS SO ORDERED.

GO BACK

b. Step-plus-Function

Masco argues that the court erred in applying § 112, paragraph 6 to the fourth step of the methods set forth in Claim 1 of the '068 patent and Claim 1 of the '711 patent. In particular, it argues that the court erred in holding that the phrase "transmitting a force" used in those claims was properly interpreted as a function, not as an act. The government responds that the phrase is too amorphous to be interpreted as an act. We agree with Masco.

Section 112, paragraph 6, provides that:

An element of a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

35 U.S.C. § 112, paragraph 6 (2000). It is well established that this statutory provision can apply not only to a combination of mechanical elements, but also to "a combination of . . . steps in a process claim." O.I. Corp. v. Tekmar Co., 115 F.3d 1576, 1582, 42 U.S.P.Q.2D (BNA) 1777, 1781 (Fed. Cir. 1997) (quoting P.J. Federico, Commentary on the New Patent Act, 35 U.S.C.A. Vol. 1, p. 25 (1954), reprinted in 75 J. Pat. & Trademark Off. Soc'y 161, 186 (Mar. 1993)). The use of the word "means" to describe a claim limitation "gives rise to a presumption that the inventor used the term advisedly to invoke the statutory mandates for means-plus-function clauses." Sage Prods., Inc. v. Devon Indus., Inc., 126 F.3d 1420, 1427, 44 U.S.P.Q.2D (BNA) 1103, 1109 (Fed. Cir. 1997) (quoting York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1574, 40 U.S.P.Q.2D (BNA) 1619, 1623 (Fed. Cir. 1996)). Similarly, in the context of method claims, the use of the term "steps for" signals the drafter's intent to invoke § 112, paragraph 6. Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583, 39 U.S.P.Q.2D (BNA) 1783, 1785 (Fed. Cir. 1996). However, even where the drafter employs the "step for" language, "section 112, P 6 is implicated . . . only when steps plus function without acts are present." O.I. Corp., 115 F.3d at 1582, 42 U.S.P.Q.2D (BNA) at 1782.

Claim 1 of both the '068 and '711 patents sets forth a method of controlling a lock, comprising a number of steps. The fourth step of the method of Claim 1 of the '068 patent is set forth below.

The method comprising the steps of . . .

transmitting a force applied to the dial to the lever after the lever and the dial have been operably connected to drive the lever to a position where the protrusion can contact the surface of the cam wheel in such a manner that the lever will be pulled by the cam wheel during rotation of the cam wheel.

'068 patent, col. 8, ll. 23, 37-42. The fourth step of the method of Claim 1 of the '711 patent is similar; it is reproduced below.
The method comprising the steps of...

transmitting a force applied to the knob to the lever through the rigid connection after the lever and the knob have been operably connected to drive the lever to a position where the protrusion can contact the surface of the cam wheel in such a manner that the lever will be pulled by the cam wheel during rotation of the cam wheel.

'711 patent, col. 8, ll. 20-21, 34-40. Neither of these claims employs the "step for" language that signals the drafter's intent to invoke § 112, paragraph 6; rather, the claims employ the term "steps of." Thus, there is no presumption that these limitations are in step-plus-function format.

In construing these limitations, the Court of Federal Claims properly examined the claim limitations to see whether any act was present, stating that "if an act is present, then the limitation is not a step plus function limitation." Claim construction ruling Masco, 47 Fed. Cl. at 453. In its assessment of whether an act was present in each claim limitation, the court followed the reasoning of Judge Rader's concurrence in Seal-Flex, Inc. v. Athletic Track and Court Construction, 172 F.3d 836, 50 U.S.P.Q.2D (BNA) 1225 (Fed. Cir. 1999). In his opinion, Judge Rader drew the following distinction between acts and functions under § 112, paragraph 6:

the "underlying function" of a method claim element corresponds to what that element ultimately accomplishes in relationship to what the other elements of the claim and the claim as a whole accomplish. "Acts," on the other hand, correspond to how the function is accomplished.

Id. at 849-50, 50 U.S.P.Q.2D (BNA) at 1234.

The court held that "transmitting" was a function rather than an act, reasoning that "the word 'transmitting' without more does not explain how the force is transmitted." Claim construction ruling Masco, 47 Fed. Cl. at 455. Since in the court's view this limitation set forth a function without an act, the court held that it was a step plus function limitation. Id.

We do not agree. Where the claim drafter has not signaled his intent to invoke § 112, paragraph 6 by using the "steps for" language, we are unwilling to resort to that provision to constrain the scope of coverage of a claim limitation without a showing that the limitation contains nothing that can be construed as an act. Method claims are commonly drafted, as in this case, by reciting the phrase "steps of" followed by a list of actions comprising the method claimed. An application of § 112, paragraph 6 in the present circumstances would render the scope of coverage of these method claims uncertain and disrupt patentees' settled expectations regarding the scope of their claims. "Courts must be cautious before adopting changes that disrupt the settled expectations of the inventing community." Festo Corp. v. Shoketsu Kinzoku Kogyo Kabushiki Co., 535 U.S. 722, 152 L. Ed. 2d 944, 122 S. Ct. 1831, 1834, 62 U.S.P.Q.2D (BNA) 1705, 1713 (2002). We thus hold that where a method claim does not contain the term "steps for," a limitation of that claim cannot be construed as a step-plus-function limitation without a showing that the limitation contains no act.

Such is not the case here. The underlying function of the "transmitting a force" limitations, or in Judge Rader's formulation, what those limitations ultimately accomplish in relation to what the other limitations and each claim as a whole accomplish, is to drive the lever into the cam. A standard mechanical engineering dictionary defines "transmission" as "[a] term applied to various methods of transmitting and transforming power as by (a) a line shaft, (b) belts and pulleys, and (c) gears." G.H.F. Nayler, Dictionary of Mechanical Engineering 406 (3d ed. 1985). A general unabridged dictionary defines "transmit" as used in mechanics and physics to mean "to cause (light, heat, sound, etc.) to pass through a medium; also, of a medium, to allow (light, etc.) to pass through; to conduct. Also, to convey (force or movement) from one part of a body, or of mechanism, to another." Oxford English Dictionary, Vol. XVIII 415 (2d ed. 1989). "Transmitting a force" describes how the lever is driven into the cam. In other words, "transmitting" in the sense of causing a force to be conveyed through a medium by mechanical parts is an act, since it describes how the function of the "transmitting a force" limitation is accomplished. Accordingly, Masco has failed to show that the "transmitting a force" limitations contain no act, we reverse the holding of the Court of Federal Claims and hold that the "transmitting a force" limitation of Claim 1 of each of the '068 and '711 patents is not a step-plus-function limitation.
7. (Substantially) Transparent

Defendants' Proposed Construction: "Substantially transparent" means transmitting light without appreciable scattering in a manner such as ordinary window glass so that objects placed behind the placard are clearly distinguishable.

 Plaintiff's Proposed Construction: Leave undefined.

The Court's Claim Construction For Transparent: "Transparent" means transmitting light without appreciable scattering in a manner such as ordinary window glass so that objects placed behind the placard are clearly distinguishable.

Claim 2 states as follows:

2. The method of claim 1 wherein the provided placard is substantially transparent and printing is applied to one of the faces under the coating of said one of the faces.

MPT argues that "transparent" should not be defined because its common English meaning is clear. The problem with this argument is that the industry definitions provided by Defendants and incorporated into Defendants' proposed construction are entirely consistent with the Court's understanding of the common English meaning of transparent. The technical references state as follows:

. "TRANSPARENT Transmitting light without appreciable scattering so that objects beyond are clearly distinguishable." (TLM p. 63).
. "TRANSPARENT LABEL A pressure sensitive label whose face material, adhesive and protective coatings, transmit light so that objects can be seen through it." (TLM p. 63).
. "Transparent - The ability of a material to transmit light without any appreciable scattering. Objects viewed through transparent materials are clearly distinguishable and are therefore also described as 'clear' or 'glass clear'" (Fairley p. 214).
. "Transparent label - Pressure-sensitive label in which the face material, adhesive and any protective coating transmit light and through which objects can be clearly seen. A transparent label on a clear bottle will allow the color, nature and volume of the contents of a bottle to be viewed through the label. See also 'No-label look'." (Fairley p. 215).

Transparent has a well established meaning in the art and a person of ordinary skill in the art would recognize that meaning in the language of Claim 2. However, the Court recognizes that Claim 2 describes a substantially transparent placard. Neither party has attempted to explain to the Court how a substantially transparent placard differs from a transparent placard. Thus, the Court adopts Defendants' definition, but only for the term "transparent."

4221

A. "transparent protective coating… defining a barrier to prevent injury to said photographic print from foot traffic and other objects passing over the floor tile"

a. Parties' Positions

The parties propose the following constructions for "transparent protective coating … defining a barrier to prevent injury to said photographic print from foot traffic and other objects passing over the floor tile," which is present in the independent claims 1, 4, and 21 of the ‘632 Patent. The only dispute between the parties appears to be whether construction of the term should include a requirement that the coating be 5 millimeters thick or more.

Plaintiff
Plain meaning
Alternatively, "a layer through which light can pass affording defensive or safeguarding properties … serving as an [sic] defense or barricade."

Defendants
A clear barrier that has a thickness of about 5 millimeters or more and prevents injury to the photographic print from foot traffic and other objects passing over it.

Alternatively, INDEFINITE
Plaintiff argues that a construction is not necessary and that the plain meaning should apply. Dkt. No. 104 at 19. Plaintiff offers, in the alternative, a construction that combines common dictionary definitions for the terms "transparent," "protective," "coating," and "barrier." Id. at 20.

Defendants argue that the patentee limited the scope of the claimed protective coating during prosecution to overcome prior art. Dkt. No. 110 at 21. The original language of the claims did not include the present "transparent protective coating" language but required that the floor tiles have a "clear protective coating." These original claims were rejected as obvious over the Muzik patent in combination with the Payne reference. Id. The Muzik reference discloses a vinyl protective coating of about 4-5 mils, 1 the same thickness as the "clear protective coating" in a dependent claim of the original application. The patentee subsequently replaced "clear protective coating" with "transparent protective coating" in the claims and changed the claimed thickness from 5 mils to "about 5 millimeters" (approximately 197 mils). Defendants argue that because of the patentee's distinguishing the prior art and the simultaneous amendments, she has surrendered a protective coating of 5 mils from the scope of the claims. Dkt. No. 110 at 23. Defendants add that the claim term would be indefinite without a limitation that the thickness be 5 millimeters or more. A person of ordinary skill in the art would not be able to determine what would qualify as a protective coating within the scope of the patent -- other than the 5 millimeters disclosed in the preferred embodiment, Defendants argue. Id.

--- Footnotes ---

1 One "mil" is equal to one one-thousandth of an inch. As a reference, most plastic credit and debit cards are 30 mils (or 0.03 inches) thick.

--- End Footnotes ---

Plaintiff replies that limiting the thickness of the protective coating to 5 millimeters during prosecution was a mistake. Dkt. No. 119 at 5. Plaintiff cites to a declaration of the inventor, Darcy Bisker, which states that a coating of 5 millimeters would be unsafe and would defeat the purpose of the invention. Id. Plaintiff also references that the preferred embodiment describes the use of Lustex 5 brand overlaminate, which is 5 mils thick. According to Plaintiff, "this shows that one of ordinary skill in the area of art would have understood that the preferred coating was close to 5 mils -- not 5 millimeters because such person would be familiar with 'Lustex 5[.]'" Id. (emphasis in original).

b. Court’s Construction

The dispute between the parties regarding this term's construction is whether the patentee has disclaimed a protective coating of less than 5 millimeters. Defendants submit that prosecution disclaimer works to limit the scope of the claim. Plaintiff submits that claim differentiation and mistake support its construction.

The patent specifically enumerates the thickness of the protective coating in two places: in the Description of the Preferred Embodiment ("The clear vinyl layer 2 is a durable five millimeter thick vinyl." '632 Patent col.3 ll.32-33) and in claim 6 ("The floor tile of claim 5, wherein said protective coating has a thickness of about 5 millimeters."). These two instances alone do not support a narrowing the scope of the asserted claims.

First, the statement from the Description of the Preferred Embodiment is just that, a description of a preferred embodiment, and cannot, alone, serve to impart a restriction of claim scope. Phillips, 415 F.3d at 1323 ("[A]lthough the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments."). Simply, the Court will not import a limitation from the preferred embodiment into the claims.

Second, the doctrine of claim differentiation precludes construing the term to include a thickness of "about 5 millimeters." The doctrine of claim differentiation refers to the rebuttable presumption that limitations found within the dependent claims should not be read into the associated independent claim. Karlin Tech, Inc. v. Surgical Dynamics Inc., 177 F.3d 968 (Fed. Cir. 1999). That is, there is a rebuttable presumption that different claims have different scopes. Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374 (Fed. Cir. 2006). Defendants correctly point out, however, that their proposed construction would not be coextensive with claim 6 to the extent that the coating is thicker than "about 5 millimeters." Dkt. No. 110 at n.9.
Finding no support in the claims or the specification for Defendant's limitation, the Court proceeds to an analysis of the prosecution history where, Defendants argue, the patentee expressly disclaimed a coating of 5 mils. Although the prosecution history is relevant to claim construction, the prosecution history may not be used to infer a narrowing of a claim absent the applicant's clear and unmistakable disavowal of claim scope. Omega Eng'g Inc. v. Raytek Corp., 334 F.3d 1314, 1326 (Fed. Cir. 2003); Amgen Inc. v. Hoechst Marion Roussel Inc., 314 F.3d 1313, 1327 (Fed. Cir. 2003). The question, then, is whether the statements relied upon by Defendants constitute a clear and unmistakable disavowal of claim scope.

The original claims of the '632 Patent application were rejected by the PTO as being obvious under 35 U.S.C. § 103 in light of the Payne, Travis, and Muzik references. Dkt. No. 110-5 at 3-4. According to the examiner:

[I]t would have been obvious to one of ordinary skill in the art motivated by the desire to produce a photographic floor tile to use a protective coating from Muzik and enlarge the photographic print from the teaching of Travis in Payne in order to achieve desirable printing results depending in [sic] the intended use. Id. at 4. In response, the patentee explained that the Muzik reference disclosed a "laminate for mounting a photographic print" and that "the photograph is backed by a flat mounting base[,]" Dkt. No. 110-6 at 11. The patentee further distinguished her invention from the Muzik reference:

Muzik primarily teaches a particular method of laminating a photograph or graphic print for purposes of displaying such a print. Furthermore, Muzik simply discloses the possibility of mounting a laminated print on a horizontal surface such as a table or floor. However, there is no suggestion that the horizontally-mounted photograph could be used as a floor tile or that it could be used as a flooring surface. In fact, Muzik teaches away from such a use. If one were to use the foam board mounting base 15 as described in column 3, lines 35-45, and mount the photograph would be [sic] crushed by foot traffic and the photograph would be injured. In addition, there is no disclosure or suggestion to provide a protective coating as [a] barrier to prevent injury to the photographic print from foot traffic. The only protection disclosed for the transparent sheet is from skin oils resulting from handling (See column 4, lines 35-37).

By this, Defendants argue, the patentee surrendered any and all claim scope encompassing protective coating of about 5 mils or less because a person of ordinary skill in the art would not know what would qualify as a "transparent protective coating." Dkt. No. 110 at 23.

On balance, Defendants' prosecution disclaimer argument fails. The claim language at issue does not speak to a specific thickness, and the patentee's comments distinguishing the prior art do not constitute a clear and unmistakable disavowal of claim scope. First, the patentee distinguished multiple differences between its invention and the Muzik reference including characterizations that the Muzik reference teaches away from and is inconsistent with the claimed invention. See Gart v. Logitech, Inc., 254 F.3d 1334, 1342 (Fed. Cir. 2001) (refusing to limit claim because, while the patentee distinguished his preferred embodiment from the prior art on the basis of a claimed feature, patentee also noted that those same references did not contain all of the features of the invention or were incompatible with the elements needed for the claimed invention).

Furthermore, Defendant has not shown that the PTO examiner rejected the claims based on the thickness of the coating. This weighs against a finding that a clear disavowal or restriction was made. Nystrom v. Trex Co., 424 F.3d 1136, 1147-1148 (Fed. Cir. 2005) ("The examiner eventually allowed claims 1-14 and 18 because the 'prior art fail[ed] to teach both sides of the board with a curved configuration,' not because the invented board specified a particular radius of curvature ratio.").

Defendants argue, in the alternative, that if the claims of the '632 Patent are not limited to a protective layer about 5 millimeters or more, then the claim becomes insolubly ambiguous and therefore indefinite. Dkt. No. 110 at 24. A claim is indefinite under § 112 P2 if it is insolubly ambiguous and no narrowing construction can properly be adopted. Amgen Inc., v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1342 (Fed. Cir. 2003). If one skilled in the art would understand the bounds of the claim in light of the specification and other intrinsic evidence, then the claim does not fail for indefiniteness. Morton Int'l Inc. v. Cardinal Chem. Co., 5 F.3d 1464, 1470 (Fed. Cir. 1993). To put it another way, the question is whether a person of ordinary skill in the art reviewing the intrinsic record would understand what constitutes a transparent protective coating within the scope of the patent.

In this case, a person of ordinary skill at the time would recognize the functionality of the claim's transparent protective coating.
coating is not dependent on a specific thickness, but whether it protects the print from foot traffic or the like.

In sum, Defendants have not demonstrated that the patentee limited the scope of the transparent protective coating to require that the coating be 5 millimeters or more. Instead, the claim term itself requires that the coating -- whatever its thickness -- be sufficient to protect the photographic from injury caused by foot traffic or the like. Thus, the Court construes the term "transparent protective coating... defining a barrier to prevent injury to said photographic print from foot traffic and other objects passing over the floor tile" to mean "a transparent barrier of sufficient thickness to protect the photographic print from injury that would otherwise be caused by foot traffic and other objects passing over it."

During prosecution of the above phrases, claim 35 (and claim 145 with respect to "transporter . . .") were amended to remove the § 112, P 6 language. The patentee, however, did not make any other changes to the claim. With respect to "transporter . . .," the patentee did not amend dependent claims 58 and 60, resulting in "transporter" providing the antecedent basis for "transport means." Likewise, as to "controller . . .," the patentee did not amend the patent's corresponding dependent claims to remove the word "means." The defendants seize on these failures to support their argument that § 112, P 6 applies.

The court disagrees. Notwithstanding the failure to carry the amendments through to all of the limitations reciting the word "means," the terms "controller" and "transporter" connote sufficient structure to avoid application of § 112, P 6. The terms do not use the word "means," and this gives rise to a presumption that the limitations are not drafted in means-plus-function form. The controller limitation provides additional functions performed by the controller, thus further defining the type of controller covered by the claim. Much like the circuit addressed in Abacus and the controller addressed in 911EP, the term "controller" recites sufficient structure.

With respect to the term "transporter," the court concludes that the analysis in Lighting World is applicable. The term "transporter," although somewhat generic, implies that the structure is a device which transports something else. Read in the context of the claim language, it is a device which is operatively connected to the capture system for moving the system in response to the vend control signal. The fact that a large number of devices may qualify as a "transporter" does not mean that the claim is drafted in means-plus-function form. The absence of the term "means" gives rise to a presumption that § 112, P 6 does not apply. The defendants have not overcome that presumption in this case.

The district court defined "transverse holes" as "holes across the butt portion of the nail." Stryker argues that this claim term should be limited to holes that are perpendicular to the nail shaft, excluding from the claim scope holes that are tilted so that one end of the hole is vertically offset from the other end. Again, this argument is an improper attempt to read a feature of the preferred embodiment into the claims as a limitation.

Stryker's argument for a narrow reading of "transverse" stems from the fact that "[e]very description of the transverse holes in the '444 patent contemplates a perpendicular hole." This is a correct characterization of the patent: every figure which illustrates the holes shows them going perpendicularly through the shaft, and the written description characterizes the holes in Figure 2 as "perpendicular to the portion of the nail axis at the butt portion 14 of the nail." '444 patent col.2 ll.58-59. However, Figure 2 and the text characterizing it simply discloses a single, preferred embodiment of the invention. "[A]lthough the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments." Phillips, 415 F.3d at 1323; see also Comark, 156 F.3d at 1186-87.
The plain meaning of Claim 1 covers more than the particular embodiment shown in the figures. While the disclosed embodiment possesses "perpendicular" holes, the claim language covers all "transverse" holes -- a word that does not necessarily imply right angles. Moreover, the patentees' description of their preferred embodiment itself implies a difference between the words "perpendicular" and "transverse." The written description states that Figure 2 "illuminates a plurality of transverse holes, each of which is . . . perpendicular to the portion of the nail axis at the butt portion 14 of the nail." '444 patent col.2 ll.56-59. This implies that a "transverse" hole need not be "perpendicular" -- if it were, the patentee would not have needed to clarify, in addition to being transverse, were perpendicular to the nail axis. Just as in Phillips, where the asserted claim mentioned "steel baffles" and hence "strongly imply[ed] that the term 'baffles' does not inherently mean objects made of steel," 415 F.3d at 1314, this usage of language is strong evidence that the patentee considered "transverse" and "perpendicular" to have distinctly different meanings.

The intrinsic evidence of the specification therefore suggests that the patentees knew how to restrict their claim coverage to holes passing through at right angles. They could have used the word "perpendicular," as they did in discussing their preferred embodiment. Instead, they chose a different term that implies a broader scope. The intrinsic evidence does not indicate that one of skill in the art would believe the patentees meant "perpendicular" when they said "transverse." There is very little indication that the patentees considered perpendicularity important to their invention. The patentees tout the virtue of their preferred hole orientation only once, noting that "'[t]he predictability of fracture modes makes the orientation of holes in the illustrated embodiment suitable in most cases." '444 patent col.4 ll.65-67 (emphasis added). Far from demonstrating that "the patentee[s] . . . intend[ed] for the claims and the embodiments in the specification to be strictly coextensive" with respect to this limitation, Phillips, 415 F.3d at 1323, this statement admits that the disclosed perpendicular hole orientation may not always be ideal. See '444 patent col.5 ll.2-4 (suggesting that, if holes are not "ideally situated, the surgeon may slightly rotate the nail to achieve a more favorable alignment"). Nowhere in the specification or the prosecution history do the patentees criticize or distinguish tilted, non-perpendicular holes.

The dissent states that the specification language which discloses only perpendicular holes should be deterministic of the claim scope. In particular, it points to three instances in the written description where "transverse holes" are described as "perpendicular." Dissent at 3-4 (citing '444 patent col. 2 ll.57-59; col.3 ll.1-3; col.3 ll.9-11). All three of these instances appear in a textual description of the patent's Figure 2, indicating that the holes depicted in that figure are perpendicular to the nail axis. Thus, while the dissent emphasizes the fact that there are three references to "perpendicular" holes in the specification, its argument is ultimately premised on characteristics which the patentee has attributed to a single preferred embodiment. In the context of this patent, such an argument must be contradicted by "our repeated statements that limitations from the specification are not to be read into the claims." Comark, 156 F.3d at 1186; see also id. at 1187 ("[T]he language that [the defendant] argues should limit claim 1 is clearly found in the . . . patent's description of the preferred embodiment. It is precisely against this type of claim construction that our prior case law counsels.").

By highlighting the specification phrase "each of which is defined" and by describing that phrase as "important[ly]," Dissent at 5, the dissent appears to suggest that the patentee has in some sense imposed a limiting definition upon the word "transverse." But the use of the word "defined" here does not imply a lexicographic definition, especially not a definition of "transverse" to mean "perpendicular." Instead, the statement that the holes of the cited embodiment are "defined on . . . an axis" merely introduces the useful abstract concept of a "hole axis," later employed in the claims to describe the orientation of the holes with respect to each other. See '444 patent, Claim 1, col.5 ll.53-54 ("the three hole axes are angularly offset from each other . . ."). The claims repeatedly echo this form of usage of the word "define." See, e.g., '444 patent Claim 1, col.5 ll.51-53 ("the butt portion . . . defining a plurality of at least three transverse holes, each defining a hole axis") (emphasis added); Claim 2, col.5 ll.57-58 ("the curved shank includes a curved portion defining a curved central axis"); Claim 3, col.5 ll.60-61 ("the butt portion defines a central axis"). If the word "define" were always to be an important signifier of limitation, this claim language would indicate that the butt portion has been defined to be transverse holes, that those holes in turn have been defined as hole axes, and that the curved portion and butt portion -- physical parts of the nail -- have each been dubbed identical to an imaginary central axis. These interpretations are incorrect, but they are the natural consequence of finding a restrictive definition of a term anywhere the word "define" might appear in this patent, regardless of context. The specification does not define "transverse" and "perpendicular" to be coequal in meaning.

The fact that the term "transverse" has a broader scope than "perpendicular" also distinguishes this case from Nystrom v. Trex Co., 424 F.3d 1136 (Fed. Cir. 2005), relied upon by the dissent. See Dissent at 5-6. In Nystrom, "both parties acknowledge[d] the ordinary meaning of 'board' as 'a piece of sawed lumber,'" but the patentee sought to have that claim
The dissent cites to other patents whose usage of "transverse" arguably supports its conclusion. Dissent at 8-9. One of them, U.S. Patent No. 5,697,934, is purely extrinsic evidence and therefore merits little consideration. See Phillips, 415 F.3d at 1317. The other, U.S. Patent No. 4,475,545, is cited by the '444 patent and is part of the intrinsic record. However, it was not "created by the patentee in attempting to explain and obtain the patent." Id. Its usage is not that of this patentee, and so it also merits less weight than the evidence of the patentee's own words. While these patents merit some consideration, the specification and claims of the '444 patent itself should be given significantly greater weight. Id. (noting that prosecution evidence "is less useful for claim construction purposes").

A proper reading of the intrinsic evidence indicates that where the patentees discussed the perpendicular holes of their preferred embodiment, they were not narrowly defining the term "transverse" or otherwise limiting the claims, but merely discharging their statutory duties "to teach and enable those of skill in the art to make and use the invention and to provide a best mode for doing so." Phillips, 415 F.3d at 1323. That preferred embodiment cannot be the only product covered by the claims; if it were, the claims themselves would be unnecessary. The district court's construction of "transverse holes" is correct.

2 Observing that the district court defined "holes" as "openings through the butt portion of the nail" and "transverse" as "being across or set crosswise," the dissent argues that these two definitions imply that "transverse holes" has been construed to mean "openings through across the butt portion of the nail." Dissent at 7. If the district court's definitions of those two words are so concatenated, that is indeed the result. We of course do not propound such a construction. Neither did the district court: after defining "transverse" and "holes," it defined the phrase "transverse holes" as "holes across the butt portion of the nail." Order on Claim Construction at 1. The construction of the disputed phrase as a whole is correct, and that construction is what we affirm today. Our de novo review means that we need not decide whether the logic or subsidiary definitions used by the district court to reach the correct construction were sound. Likewise, de novo review makes the atmospherics of the Markman hearing, see Dissent at 1-3, legally irrelevant here. We review only the district court's finished product, not its process. Furthermore, the dissent's criticism of that process contends that Phillips prohibited the district court from beginning its interpretive inquiry by consulting a dictionary. Dissent at 3 ("In accordance with Phillips, the interpretative inquiry should begin not with a dictionary definition . . . ."). Although in Phillips we rejected an approach in which a broad dictionary definition is adopted and then whittled down only if contradicted by the specification, 415 F.3d at 1321, we did not prohibit the use of dictionaries in claim construction, nor did we define at what point in the claim construction analysis they may be consulted.
Moreover, the court seemed to disregard the briefs in favor of off-the-cuff attorney argument during claim construction. In fact, when Stryker argued that Acumed's attorneys were changing their claim construction during the course of the hearing, the district court responded: "Let's not worry about changing. I'm going to keep you all focused right on the task at hand. I don't care what happened before today. I care what's going on here." After hearing arguments from the parties regarding the disputed claim terms and on the appropriateness of the dictionary definitions, the district court resolved each issue orally during the hearing. One week later, the court issued a one-page formal Order on Claim Construction that simply reiterated the court's oral rulings. Acumed LLC v. Stryker Corp., No. 04-cv-513-br (D. Or. Oct. 14, 2004).

--- Footnotes ---

1 It should be noted that the claim construction hearing in this case occurred before this court's en banc decision in Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005). Thus, the district court may have been following the methodology described in Texas Digital Systems, Inc. v. Telegenix, Inc., 308 F.3d 1193, 1201-02 (Fed. Cir. 2002), which relied heavily on the use of dictionaries to ascertain the plain meaning of a claim term. After our Phillips decision, which clarified that the Texas Digital approach was not appropriate, the plaintiff asked the district court here to reconsider her claim construction, but that request was denied.

--- End Footnotes ---

While I acknowledge that there are not formal requirements for a district court's methodologies when conducting claim construction hearings and issuing related orders, I raise this concern because I believe the district court's methodology led it astray from determining the "the meaning that the term "transverse holes" would have to a person of ordinary skill in the art . . . in the context of the entire patent, including the specification." Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005) (en banc). When one properly begins this claim construction inquiry with the intrinsic evidence, rather than dictionary definitions, it is evident that the district court's construction of "transverse holes" is in error.

With respect to the claim term "transverse holes," the district court utilized the dictionary to first determine that a "hole" is "an opening through something." The district court then referred to the dictionary and found two definitions for the term "transverse": (1) acting, lying, or being across: set crosswise; (2) made at right angles to the anterior-posterior axis of the body." The district court concluded that we should construe the claim term in accordance with the broader of the two dictionary definitions 2 because there is no express disavowal of claim scope in the specification. This approach was specifically rejected by this court sitting en banc in Phillips, 415 F.3d at 1320, and we have continued to reject this approach to claim construction. See On Demand Mach. Corp. v. Ingram Indus., Inc., 442 F.3d 1331, 1340 (Fed. Cir. 2006).

--- Footnotes ---

2 The court emphasized that the broader definition appeared as the "number one" definition in Webster's dictionary. It should be noted, however, that this order is not indicative of importance or primacy, but merely reflects historical usage. MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY (11th ed. 2003) 19a ("Order of Senses").

--- End Footnotes ---

In accordance with Phillips, the interpretive inquiry should begin not with a dictionary definition, but with the patent itself, to ascertain what an ordinarily skilled artisan reading the patent would understand the claim term to mean. Phillips, 415 F.3d at 1321. The intrinsic evidence provides no support for the broader of the two dictionary definitions set forth above (i.e., that "transverse" means "acting, lying, or being across; set crosswise"), but fully supports the narrower definition (i.e., that "transverse" means "made at right angles to the anterior-posterior axis of the body"). Each of the eight transverse holes described in the specification are specifically described as being perpendicular. Id. at col.2 ll.57-59 (describing "a plurality of transverse holes, each of which is defined on a respective axis intersecting the nail axis 22, and perpendicular to the portion of the nail axis at the butt portion 14 of the nail"); col.3 ll.1-3 ("transverse hole 44a is oriented . . . perpendicular to the nail axis 22"); col.3 ll.9-11 ("the distal holes are . . . perpendicular to the butt end portion of the nail axis") (emphases added). The majority suggests that the use of both words "implies a difference between the words 'perpendicular' and 'transverse.'" Maj. Op. at 11. The majority contends that if transverse was meant to be construed as perpendicular, "the patentee would not have needed to clarify that these holes, in addition to being transverse, were perpendicular to the nail axis." Id. I disagree. First, the patentee used the two words to clearly specify which of the definitions of transverse applied.
to his invention; the purpose of using the word "perpendicular" was to further describe what the inventor meant by the term "transverse," not to distinguish it as the majority suggests. Second, to say that something is perpendicular also requires mention of a reference plane or line to which the object is located at a right angle. Here, the patent specification limits the discussion of "transverse holes" to holes having an axis perpendicular with respect to the nail axis at the butt portion. '444 patent, col.2 ll.56-59. That was the point of using the word perpendicular in the specification. Thus, by utilizing the word "transverse," the patentee did not need to repeat in the claim that each hole was perpendicular to the nail axis at the butt portion.

The specification describes "three sets of transverse holes." Id. at col.2 l.62. With reference to Figures 1 and 2 of the patent, reproduced below, the first set includes four proximal transverse holes (44a-44d), the second set is one intermediate transverse hole (46), and the third set includes three distal transverse holes (48a-48c). Each of these eight holes is then described and shown in the accompanying figures as being perpendicular to the nail axis 22. Id. at col.2 l.56-col.3 l.11. Most importantly, the specification states that "a plurality of transverse holes each of which is defined on a respective axis intersecting the nail axis 22, and perpendicular to the portion of the nail axis at the butt portion 14 of the nail." Id. at col.2 ll.56-59 (emphases added). Thus, the specification limits each of the transverse holes by the common characteristic that each has an axis perpendicular to the nail axis at the butt portion.

GET DRAWING SHEET 1 OF 1.

There is not a single non-perpendicular, "transverse" hole shown or described in the patent. Construing "transverse" to include something other than perpendicular -- in spite of the repeated, narrow usage of that term in the specification -- would provide patent coverage that is broader than what the inventor actually invented and disclosed in his specification, which clearly should have been the starting point for claim construction. Smith v. Snow, 294 U.S. 1, 14, 55 S. Ct. 279, 79 L. Ed. 721, 1935 Dec. Comm'r Pat. 757, (1935) (stating "if the claim were fairly susceptible of two constructions, that should be adopted which will secure to the patentee his actual invention"). Since Phillips, we have repeatedly rejected the concept of construing claim terms to have meanings broader than the meaning derived from the intrinsic evidence. For example, in Nystrom v. Trex, Co. this court stated:

[i]n the absence of something in the written description and/or prosecution history to provide explicit or implicit notice to the public -- i.e., those of ordinary skill in the art -- that the inventor intended a disputed term to cover more than the ordinary and customary meaning revealed by the context of the intrinsic record, it is improper to read the term to encompass a broader definition simply because it may be found in a dictionary, treatise, or other extrinsic source.

424 F.3d 1136, 1145 (Fed. Cir. 2005); see also Primos, Inc. v. Hunter's Specialties, Inc., 451 F.3d 841, 845, 847-48 (Fed. Cir. 2006) (affirming district court's claim construction after district court rejected dictionary definition that was broader and inconsistent with the use of the claim term in the patent at issue); Old Town Canoe Co. v. Confluence Holdings Corp., 448 F.3d 1309, 1318 (Fed. Cir. 2006) (patentee is "not entitled to a claim construction divorced from the context of the written description and prosecution history"); Atofina v. Great Lakes Chem. Corp., 441 F.3d 991, 996 (Fed. Cir. 2006) (quoting Free Motion Fitness, Inc. v. Cybex Int'l, Inc., 423 F.3d 1343, 1348-49 (Fed. Cir. 2005) for the proposition that "in those circumstances where reference to dictionaries is appropriate, the [court's] task is to scrutinize the intrinsic evidence in order to determine the most appropriate definition" (emphasis added)); In re Johnston, 435 F.3d 1381, 1384 (Fed. Cir. 2006) (citing Phillips, 415 F.3d at 1303 for the proposition that "[i]t is well established that dictionary definitions must give way to the meaning imparted by the specification"); Network Commerce, Inc. v. Microsoft Corp., 422 F.3d 1353, 1359-60 (Fed. Cir. 2005) (rejecting proposed construction of the term "download component" based on the combination of two dictionary definitions as untenable "in light of the specification").

Patent scope should be coextensive with what the inventor invented as evidenced by what is disclosed in the patent specification. Netword, LLC v. Centraal Corp., 242 F.3d 1347, 1352 (Fed. Cir. 2001) (stating that the claims should not "enlarge what is patented beyond what the inventor has described as the invention"); Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998) ("The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction."). Thus, where, as here, the intrinsic evidence clearly provides one meaning for the term "transverse," it is inappropriate to give that term a broader interpretation, particularly where the only support for the broader interpretation is extrinsic evidence -- in this case, a dictionary (which supports the narrower construction as well).
Moreover, the district court's interpretation of "hole," which neither party is challenging, makes the majority's interpretation of "transverse" redundant and nonsensical. The court found that the word "holes' in the phrase 'defining a plurality of at least three transverse holes,' means openings through the butt portion of the nail." Claim Construction Order, at 1. This makes sense in the context of orthopedic implants, because a hole is necessarily through the part, which in the case of an intramedullary nail is to accept a screw. Here, the majority's definition of "transverse" as "being across" is redundant when read together with the definition of holes. It makes the phrase "transverse holes" mean "openings through across the butt portion of the nail." The majority's claim construction thus impermissibly renders the claim term "transverse" meaningless, a methodology that this court has repeatedly denounced. Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so."); see also Bicon, Inc. v. Straumann Co., 441 F.3d 945, 950 (Fed. Cir. 2006); Cross Med. Prods., Inc. v. Medtronic Sofamor Danek, Inc., 424 F.3d 1293, 1307 (Fed. Cir. 2005). Only if "transverse" requires perpendicularity does each claim term have a distinct meaning. 3

--- Footnotes ---

3 Claim 22, which indirectly depends from independent claim 19, further illustrates this point. Claim 22 recites "a plurality of second securement holes" in the butt portion of the claimed nail. These holes, like the transverse holes in claim 1, are required to go through the butt portion of the nail. But unlike the transverse holes, the securement holes need not be defined by an axis perpendicularly situated with respected to the nail axis at the butt portion.

--- End Footnotes ---

That "transverse" means perpendicular in direction is further supported by other intrinsic evidence, namely, other patent references cited during prosecution of the '444 patent. For example, U.S. Patent No. 4,475,545, entitled "Bone Nail," discloses a pair of holes "passing through the nail in transverse relation to its longitudinal direction and both axes of the said both pairs of holes being located in different planes extending in transverse direction relative to the longitudinal direction of the nail." '545 patent, Abstract. The first hole is defined by the nail entrance 8' and exit 8". The second distal hole is defined by the nail entrance 9' and exit 9". As shown in Figures 4 and 5, both of these holes are perpendicular to the longitudinal axis of the nail at the distal portion. The hole axes are similarly described as being located in a plane "normally extending relative to the longitudinal axis of the nail." '545 patent, col.3 ll.45-46. Thus, the usage of "transverse" in the '545 patent is consistent with the definition requiring perpendicularity.

The narrower definition of transverse is also more consistent with extrinsic evidence that demonstrates how those skilled in the art would understand the term. First, in another patent application filed within a year of the issue date of the '444 patent, the '444 patent's inventor, Randall Huebner, uses the word "transverse" in a way that clearly denotes perpendicularity in direction. There, as here, Mr. Huebner describes a "transverse hole" extending through a shaft, stating "the head [of the shaft] includes a hole extending therethrough in a direction generally transverse to the axis of the shaft." U.S. Patent No. 5,697,934, col.2 ll.45-46 (filed Dec. 2, 1996); see also id. at col.3 l.66-col.4 l.1 (describing another hole as "formed through head 50 with a central axis 54 generally transverse to elongate axis 38 of shaft 32"). Mr. Huebner's use of transverse in that application clearly shows a directional requirement implicit in the term "transverse" that is not encompassed in the broader definition accepted by the majority. Next, although the district court chose to rely exclusively on a general dictionary that was not contemporaneous with the patent, technical dictionaries, including one highly relevant to the field of orthopedic implants at the time the patent issued, define "transverse" as referring to a perpendicular direction. Dorland's Medical Dictionary defines transverse as "placed crosswise; situated at right angles to the long axis of a part." DORLAND'S ILLUSTRATED MEDICAL DICTIONARY 1735 (28th ed. 1994).

Thus, the intrinsic and extrinsic evidence establish that the '444 patent's use of "transverse" is only consistent with the narrower definition rejected by the district court and the majority opinion. The only passage of the specification which the majority relies upon to support its broader interpretation of "transverse holes" is the language "[t]he predictability of fracture modes makes the orientation of holes in the illustrated embodiment suitable in most cases." The majority suggests that this language "admits that the disclosed perpendicular hole orientation may not always be ideal." Maj. Op. at 12. I respectfully submit that the majority has taken the language out of context and imparted a meaning to it that is not correct. The entire paragraph wherein this sentence is found is discussing Figure 4 and the orientation of the holes relative to each other around the circumference of the nail, not relative to the nail axis at the butt portion 22. That paragraph focuses on the need to orient the screws "to prevent rotation or axial movement of the nail" and discusses that the screws should be located on "opposite
sides of the nail." '444 patent, col.4 l.61-65. Hence, when the very next sentence of the specification refers to the "orientation of the holes," '444 patent, col.4 l.65-67, it is doing so in the context of their placement around the nail.

Tellingly, the majority opinion offers no other support -- intrinsic or extrinsic -- for its construction, and in fact, offers no explanation at all for its conclusion that "the claim language covers all 'transverse' holes -- a word that does not necessarily imply right angles." 4 Maj. Op. at 11. What, if not the specification, is the majority using to determine the plain meaning of this term? The district court based its conclusion regarding the plain meaning of transverse on Webster's Dictionary, which it acknowledged supported both the definition across and perpendicular. In the present case, as in Nystrom, I see no reason why we should adopt one, broader, plain meaning of the term "transverse" when there is another plain meaning that is completely consistent with the intrinsic evidence. When one begins with the patent specification, in my opinion, there is no doubt which of the two meanings of "transverse" is correct.

--- Footnotes ---

4 The majority's observation that "[n]owhere in the specification or the prosecution history do the patentees criticize or distinguish tilted, non-perpendicular holes," Maj. Op. at 12, only underscores the absence of a written description broad enough to support the meaning that they attribute to the claim term "transverse."

--- End Footnotes ---

The majority attempts to distinguish the Nystrom case as a case in which the patentee "sought to have [the] claim [at issue] 'broaden[ed] . . . to encompass relatively obscure definitions that are not supported by the written description or prosecution history.'" Maj. Op. at 14 (quoting Nystrom, 424 F.3d at 1145). The majority suggests that in Nystrom "[w]e refused to impose a construction broader than the term's ordinary meaning." Maj. Op. at 14. In this case, the Webster's Dictionary which provided the basis for the district court's determination of the term's ordinary meaning included two definitions for the term transverse (across and perpendicular). Even the district court acknowledged both definitions. In this case, we must choose between two plain meanings of the word "transverse." As in Nystrom, we should interpret the claim term by reference to the specification and refuse to read the term "transverse" as encompassing meanings unsupported by even a modicum of intrinsic evidence; otherwise we give the patentee more than what was invented and disclosed to the public.

Even if I did not read the intrinsic record to clearly support the narrower of the two plain and ordinary meanings of the term "transverse," I would still be compelled by our precedent to conclude that the narrower meaning applies to this limitation. In Athletic Alternatives, Inc. v. Prince Manufacturing, Inc., this court was presented with a case in which there were two plain and ordinary meanings of a term. 73 F.3d 1573, 1579 (Fed. Cir. 1996). The court was at an impasse after concluding that the specification, the prosecution history and the doctrine of claim differentiation did not provide guidance on what the plain meaning of the claim term at issue was. Id. at 1579-81 (concluding that "the specification is completely silent with regard to the meaning" of the claim term; that there were "[t]wo strong and contradictory interpretative strands run[ning] through the patent's prosecution history . . . [that] together . . . are irreconcilable;" and that after analyzing claim differentiation "we [were] left with two equally plausible meanings of Claim 1"). Faced with such a conundrum, we resorted to the statutory basis for the claims themselves, 35 U.S.C. § 112, P 2, and concluded that

[w]ere we to allow [the patentee] successfully to assert the broader of the two senses of [the claim term] against Prince, we would undermine the fair notice function of the requirement that the patentee distinctly claim the subject matter disclosed in the patent from which he can exclude others temporarily. Where there is an equal choice between a broader and a narrower meaning of a claim, and there is an enabling disclosure that indicates that the applicant is at least entitled to a claim having the narrower meaning, we consider the notice function of the claim to be best served by the narrower meaning.

Id. at 1581.

Even if the specification was completely silent on whether the transverse holes had to be perpendicular to the nail axis at the butt portion of the nail -- which, as discussed above, I do not believe it is -- we must, according to our precedent, adopt the narrower of the two plain and ordinary meanings of the word "transverse." Accord Athletic Alternatives, 73 F.3d at 1581. The majority's rejection of Stryker's claim construction position as "an improper attempt to read a feature of the preferred embodiment into the claims as a limitation," fails to identify any language in the specification that demonstrates that the patentee contemplated anything more than transverse holes that are perpendicular to the nail axis at the butt portion. Thus,

- 4899 -
even adopting the majority's view of the intrinsic record, I cannot agree with their conclusion.

Based on the foregoing, I conclude that the district court's construction of the term "transverse holes" was improper and should be reversed. The term "transverse holes" in claim 1 of the '444 patent should be interpreted as "openings through the butt portion of the nail oriented perpendicularly with respect to the longitudinal axis of the butt portion." Because the uncontested evidence shows that the alleged infringing products do not literally infringe claim 1 of the '444 patent as properly construed, a remand on that issue would not be necessary. Acumed could, however, argue that Stryker's T2 PHN products infringe claim 1 of the '444 patent under the doctrine of equivalents. Accordingly, I would reverse the judgment of literal infringement and remand for proceedings with respect to infringement under the doctrine of equivalents.

5 Although Stryker argues that Acumed waived the doctrine of equivalents with respect to this claim element because it did not assert that theory at trial under the court's claim construction, that statement is incorrect. See Exxon Chem. Patents, Inc. v. The Lubrizol Corp., 137 F.3d 1475, 1479 (Fed. Cir. 1998) (determining that plaintiff did not waive equivalents arguments where the court's claim construction made a doctrine of equivalents argument under any other claim construction "moot").
held that, "Even when attempting to give these words their ordinary meaning" (citing Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)), and after careful consideration, it was unable to construe the phrase "transverse sectional dimensions." Order at 9. The Court agreed that one of ordinary skill in the relevant art would not be on notice that Tranquil intended a certain meaning for this phrase. Order at 9-10.

The Court remains convinced that its original determination of indefiniteness is correct, and agrees with the reasons advanced by Plaintiff. First, there is no direction that the dimensions should be taken linearly (radius or diameter), or using the cross-section of the surface area of a horizontal slice. As Plaintiff correctly points out, linear measurements meet the stated limitation, while the cross-sectional slice does not. Further, Tranquil did not instruct whether the seventy percent limitation was required throughout the length of the diaphysis or at a given slice across the surface of the diaphysis.

The Court has thoroughly reviewed Tranquil's explanations and arguments in its brief supporting reconsideration. Some of these arguments are taken from documents submitted before the U.S. Patent and Trademark Office during Reexamination. While these arguments may somewhat clarify some of the ambiguity, it does not appear that they are legally "before this Court" and available for reconsideration. The limiting, indefinite term appeared in the original patents; no clarification was applied to that term until the PTO had undertaken reexamination proceedings, which occurred after the original patents had issued. It is well-settled that, in reexamination, while new or amended claims may be examined for compliance with 35 U.S.C. § 112, original claims which are not amended cannot be examined for compliance with § 112. 37 C.F.R. § 1.552; Tennant Co. v. Hako Minuteman, Inc., 22 U.S.P.Q.2d 1161, 1167 n.6 (N.D. Ill. 1991). Indefiniteness of an original, unamended patent claim can be cured only by reissuance. 35 U.S.C. §§ 251-252. If the Court legally cannot rely on Tranquil's arguments here, then it is without a basis for changing its original ruling.

In addition, Tranquil proffers the expert testimony of Dr. James Mason of the University of Notre Dame to offer additional arguments regarding the term "transverse sectional dimensions." Initially, there is some question regarding Dr. Mason's qualifications and basis for his opinions, although the Court takes notice of Dr. Mason's extensive expertise. Second, and more importantly, the Court notes that Dr. Mason's opinions were not made a part of the Court's record for claim construction. Under the standard of review set forth above, the Seventh Circuit requires some reasonable explanation as to why Dr. Mason's opinions were not provided to the Court at claim construction. Tranquil has provided no explanation.

Third, there is some inconsistency between Tranquil's proposed definition at claim construction and Dr. Mason's definition. Dr. Mason here refers to the "area" measurements for finding the transverse sectional dimensions. Tranquil's proposed definition relied on linear dimensions to find the transverse sectional dimensions. So it appears that Tranquil is advancing two possible ways to find the dimensions. This brings the Court full circle to its original problem: the term is invalid for vagueness, because at this point, and in spite of extensive discussion on the issue, the Court still does not know which dimensions are appropriate to use in determining the transverse sectional dimensions. The Court's original ruling, that the term is invalid for vagueness pursuant to 35 U.S.C. § 112, shall stand.

A

Patent claims must "particularly point[] out and distinctly claim[] the subject matter which the applicant regards as his invention." 35 U.S.C. § 112, para. 2 (1982). "A determination of claim indefiniteness is a legal conclusion that is drawn from the court's performance of its duty as the construer of patent claims." Personalized Media Communications, 161 F.3d at 705. The perspective of a person of ordinary skill in the art at the time of the patent application governs the definiteness analysis. W.L. Gore & Assoc., Inc. v. Garlock, Inc., 721 F.2d 1540, 1556-57 (Fed. Cir. 1983). The definiteness of a patent claim depends on whether one skilled in the art would understand the bounds of the claim when read in light of the specification. Union Pac. Res., 236 F.3d at 692 (citing Orthokinetics, Inc. v. Safety Travel Chairs, Inc., 806 F.2d 1565, 1576 (Fed. Cir. 1986)). "A claim is indefinite if its legal scope is not clear enough that a person of ordinary skill in the art could determine whether a particular [product or method] infringes or not." Geneva Pharms., Inc. v. GlaxoSmithKline PLC, 349 F. 3d 1373, 1384 (Fed. Cir. 2003).

The district court found the claims of the '214 and '985 patents invalid because it found that one of ordinary skill in the art would not understand the meaning of the phrase "transverse sectional dimensions." Construction Order, 288 F. Supp. 2d at
945. The claims of the '214 and '985 patents require that the "transverse sectional dimensions" of the coated prosthesis constitute certain percentages of the "transverse sectional dimensions" of the medullary canal, defined by the cortical bone. '214 patent, col. 9, ll. 26-36; '985 patent, col. 9, ll. 17-26. A "transverse section" is a slice taken perpendicular to the vertical axis of the bone. The parties dispute which "dimensions" of the "transverse section" define the claimed percentages. Tranquil, relying on citations to the prosecution histories and expert testimony, argues that the "transverse sectional dimensions" refer to two-dimensional surface areas, or the cross-sectional area. Howmedica argues that the term is indefinite because the patent does not specify whether the term refers to a two-dimensional measurement of area or single-dimension linear measurement.

A simple example in the record points out the significant difference between a one-dimensional measurement and a two-dimensional measurement. Consider, for example, a cylindrical medullary canal having a diameter of 1 inch, and a cylindrical implant within that canal having a diameter of 0.75 inch. A one-dimensional linear measurement of the diameter of the implant is seventy-five percent of the diameter of the canal, and meets the "at least around seventy percent (70%)" limitation of the claims. On the other hand, a two-dimensional measurement of the cross-sectional area of the implant is only about fifty-six percent (56%) of the cross-sectional area of the canal and does not meet the limitation of the claims. Consequently, one of ordinary skill in the art must know which measurement to use to determine the boundary of the claims.

The record shows that one of ordinary skill in the art would readily ascertain from the written description of the patents that the "transverse sectional dimension" calls for a two-dimensional measurement. The '214 and '985 patents claim an invention that shapes the prosthesis to fit snugly inside the medullary canal. From the very outset, the written description of these patents disclose this overriding purpose of the invention. For instance, the abstract of the '214 patent states: "The prosthesis device and the method of implantation utilize an elongate stem undersized precisely with respect to a precisely formed stem socket defined by the cortical bone …" '214 patent, col. 3, ll. 52-55. The same abstract emphasizes: "This invention is based on selecting a prosthesis having a stem part which is shaped and sized to correspond substantially to the geometry of the medullary canal … and then forming a complementary stem socket in the canal which will receive the selected prosthesis." Id. at col. 3, ll. 64-65 (emphasis added). To make the invention abundantly clear, the patent repeatedly describes a very tight fit for the prosthesis. See, e.g., id. at col. 3, ll. 68-67 ("The stem must be forcibly inserted into the socket."); col. 4, ll. 3-4 ("The compressed coating provides a compression fit …"); col. 4, ll. 24-30 ("The compression fit initially instantly stabilizes the stem within its socket …"); col. 4, ll. 31-32 ("By shaping the stem part of the prosthesis to conform substantially to the geometrical shape of the medullary canal … it is now possible to obtain, at implantation, a generally uniform press fit …"); col. 4, ll. 31-32 ("Such press fit allows the stem to distribute mechanical loads to the cortical bone …") (emphasis added); '985 patent, Abstract ("The prosthesis utilizes a tapered elongate stem undersized precisely with respect to a precisely formed stem socket in the medullary canal with the stem socket defined by cortical bone …") (emphasis added).

These extensive references clarify that the invention requires a very tight fit for the prosthesis. Given the choice between a construction of "transverse sectional dimensions" that would require a relatively loose fit and a construction that would require a much tighter fit, the record shows that one of skill in the art would readily understand and adopt the latter construction. One of ordinary skill in this art would recognize that a one-dimensional linear measurement of the "transverse sectional dimensions" would defeat the purpose of the invention to provide a snug fit of the prosthesis in the medullary canal. A two-dimensional measurement, on the other hand, provides the snug fit that is the centerpiece of this invention.

This proper and evident construction also finds support in numerous references to the "cross-sectional area" in the prosecution history of both patents. See, e.g., J.A. 75 ("The existence of five sizes of prostheses does not teach anything about … whether those sizes will fill the cross-sectional area of the medullary canal.") (reexamination of the '214 patent); J.A. 101 ("Nor is there any discussion of the desirability of making the cross-sectional area of the prosthesis large in comparison to the cross-sectional area of the medullary canal as defined by the cortical bone.") (reexamination of the '985 patent) (emphases added). Thus, the applicant and the patentee both understood that the "cross-sectional dimensions" referred to in the patents meant cross-sectional areas. These references occurred during a reexamination proceeding. Thus, these references do not directly address the definiteness requirement—an assessment relevant to the time of filing, not a later reexamination proceeding. See Hybritech, Inc. v. Monoclonal Antibodies, Inc., 802 F.2d 1367, 1385 (Fed. Cir. 1986) (analyzing definiteness as of the time of filing). Nonetheless, these references to "cross-sectional areas" in the discussion between the examiner and the applicant at a later time are relevant to the meaning of "transverse sectional dimensions" to one of skill in the art at the earlier time of filing. See Kopykake
Enters. v. Lucks Co., 264 F.3d 1377, 1383 (Fed. Cir. 2001) ("The literal scope of the term is limited to what it was understood to mean at the time of filing.") (citing Schering Corp. v. Amgen Inc., 222 F.3d 1347, 1352-54 (Fed. Cir. 2000)).

To satisfy the definiteness requirement, the term "transverse sectional dimensions" also need not specify percentage limitations nor the locations along the prosthesis that the percentage must satisfy to constitute a proper dimensional fit. The patent clearly specifies that "the present invention is rooted in the recognition of the importance and criticality of the stem's transverse sectional dimensions, along the entire length thereof, relative to the corresponding transverse sectional dimensions of the medullary canal ...." ‘214 patent, col. 3, ll. 33-37 (emphasis added). Similar language also appears in the claims of both patents. See id. at col. 9, ll. 14-18 ("said stem having transverse sectional dimensions along substantially its entire length which are undersized with respect to adjacent corresponding transverse sectional dimensions of said stem socket"); ‘985 patent, col. 9, ll. 11-13 ("said stem having transverse sectional dimensions along substantially its entire length undersized with respect to corresponding transverse sectional dimensions of said socket") (emphases added). Thus the record shows that the percentage limitations of the "transverse sectional dimensions" for each portion of the bone specified in the claims must be met along "substantially the entire length" for each respective portion. Because one of ordinary skill would understand these requirements from the patent, the claim language is not indefinite. In sum, this record shows that "transverse sectional dimensions "refers to two-dimensional measurements, or the cross-sectional area. The district court erred in holding the claims of the ’214 and ’985 patents invalid under 35 U.S.C. § 112.

4228

a. "transversely extending protrusion"

The phrase "transversely extending protrusion" appears in claim 1. Boston Scientific argues that the phrase should be construed as "a protrusion that extends in the radial direction, i.e., crosswise to the long axis of the elongate member." ev3 proposes that the phrase be construed as "a protrusion that expands outward from the guidewire in a direction perpendicular and crosswise to the guidewire."

Neither party disputes that the phrase "transversely extending protrusion" has no accepted meaning within the art. Because the phrase is not defined explicitly or implicitly in the intrinsic evidence, the Court turns to the ordinary meaning of the words. The Court construes "transversely extending protrusion" as "a protrusion that extends crosswise to the long axis of the elongate member."

4229

"transversely oriented support extending across the user support"

"extending substantially across the entire lateral extent of the body pad"

The parties addressed these claims together in the hearing. Fitness Quest contends that they require substantial construction; Monti contends that no construction is required.

Fitness Quest argues that its proposed construction is warranted, based on the prosecution history and Monti's efforts to distinguish his proposed invention from the prior art -- specifically, the Harris patent referenced in Fitness Quest's initial Markman brief at 18-19 and Exhibit 9 thereto. Fitness Quest makes this leap to the prosecution history, however, without explaining why the language of the claim requires any such resort.

Under Markman, the court determines as a matter of law the scope and meaning of patent terms that are in dispute; "[t]he first step of this analysis requires the court to consider the words of the claims." Apple Computer, Inc. v. Burst.com, Inc., no. C 06-00019MHP, 2007 U.S. Dist. LEXIS 33863, 2007 WL 1342504 (N.D. Cal. May 8, 2007) *2 (citation omitted); see also Phillips, 415 F.3d at 1314.

Fitness Quest appears to be asking this Court to leapfrog over the language of the claims and the specification directly to the
prosecution history. This Court is not inclined to accept this invitation. Fitness Quest seeks to inject concepts including "extends perpendicular," "positioned vertically," "suitable distance" (which counsel at the hearing conceded could be understood to mean "sufficient distance"), that are found nowhere in the claim at issue. Monti contends that the language, when considered in the context of Claim 15, is clear and requires no construction. This Court agrees and therefore declines to construe either term.

8. "[T]rap space [or secondary settling area] between each magnet member and a magnet protector of an immediately adjacent magnet member"

This phrase is contained in an independent claim of the 781 patent, 119 an independent and dependent claim in the 386 patent, 120 and four independent claims in the 117 patent. 121

As to this phrase, the Court construes the following meaning: a catch space created between the exposed side of a magnet and the protector for the next magnet over. The Abstracts of all five patents refer to this trap space, although the 117 patent language is slightly different, calling it a secondary debris settling area instead of a trap space. The drawings for all five patents support this interpretation, illustrating a "valley" created by the fact, as discussed earlier, that the magnet protector is taller than the next magnet over. The specifications also support this interpretation, explaining that cuttings are caught in a trap formed "between a straight side of one magnet and the slanted face of the next magnet protector." 122

A. "Tray"

Claim 8 describes that the invention is a "mobile workstation" consisting of a "substantially horizontal tray supported by the chassis that defines a work surface." (178 patent, claim 8). The parties dispute how much of the invention is encompassed by the term "tray." The Plaintiff asserts that a tray is a "receptacle having a top surface, sides and a bottom." (Joint Claim Construction Statement at 5). The Plaintiff's definition includes the entire tray shelf, which visually resembles a shelf upon which a computer monitor could sit, the inside of which could house a computer terminal and keyboard. The Defendant argues that the Plaintiff's definition is too expansive, and points out that the Plaintiff's version of a tray is more like a box. (Def.'s Responsive Claim Construction Br. at 6). Instead, the Defendant defines a tray as "an open receptacle having a top surface, low sides, and a flat bottom." (Joint Claim Construction Statement at 5). Therefore, the Defendant argues that the
entire tray shelf should not be included within the tray definition, only the top board upon which a monitor might sit.

The specifications and the entirety of the patent support the Plaintiff's definition. The Defendant's definition of a tray is, in my view, more aligned with the common understanding of the term. Certainly, the Defendant's version conjures up images of a regular lunch tray. However, "[i]mportantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." Phillips, 415 F.3d at 1313. The "proper definition is the definition that one of ordinary skill in the art could ascertain from the intrinsic evidence in the record." Id. at 1314 (quoting Unitherm Food Sys., Inc. v. Swift-Eckrich, Inc., 375 F.3d 1341, 1351 (Fed. Cir. 2004)). Applying that standard to this case, it is clear that a person of ordinary skill in the art could ascertain that the Plaintiff used "tray" to encompass the entire tray shelf. The definition of tray should be "a receptacle having a top surface, sides and a bottom." (Joint Claim Construction Statement at 5).

The intrinsic record is replete with evidence that the Plaintiff used the term "tray" to encompass more than the Defendant allows. Figures 2A-2D of the patent application show that the entire tray shelf is adjustable in height. In its description of the figures, the patent application states that the figures "illustrate [the] operation of an adjustable-height horizontal tray." (the '178 patent, Col. 4, lines 33-36). Since the entire tray shelf is adjusted in height in the various figures, one reading the patent materials would understand that the horizontal tray referred to the tray shelf, and not just the top board. The top board does not adjust at all in relation to the rest of the tray shelf, and thus must be but one part of the "horizontal tray." The same is true for another set of drawings in the patent, figures 9A-9D. Again, they show the height adjustment of the entire tray shelf, which the patent calls the "adjustable-height horizontal tray." (the '178 patent, Col. 4, lines 64-67). Further, "FIG 5A is a side view of the horizontal tray of the mobile workstation." (the '178 patent, Col. 4, lines 44-46). Figure 5A is simply a side view of the entire tray shelf, to which the patent only refers to as the horizontal tray. (the '178 patent, Col. 4, lines 44-46). Another view of the tray shelf, figure 5B, states that the "sides 103 and bottom 104 [of] the horizontal tray may be formed from sheet metal." (the '178 patent, Col. 12, lines 27-43). In figure 5B, numbers 103 and 104 are clearly not part of the top board, but rather components of the tray shelf. The patent seems to recognize that its version of "tray" departs from the more common version: "For example, the chassis 14 may be a model MPC2001 . . . with the standard tray replaced by the horizontal tray 12 shown in FIG 1." (the '178 patent, Col. 8-9). The horizontal tray in figure 1 includes the entire tray shelf.

It is true that at other points the patent refers to a tray which resembles the Defendant's definition. (See, e.g., the '178 patent, Col. 8, lines 14-18) ("When the computer terminal is mounted beneath the horizontal tray, the computer terminal does not occupy the top surface of the horizontal tray."). However, as stated above, the patent also clearly states that one embodiment of mobile workstation envisions the "horizontal tray" encompassing the entire tray shelf. Because including the horizontal tray as the entire shelf is one of the patent's preferred embodiments, it would be incorrect to exclude that embodiment from the patent. "A claim construction that excludes a preferred embodiment, moreover, is 'rarely, if ever, correct.'" SanDisk Corp. v. Memorex Products, Inc., 415 F.3d 1278, 1285 (Fed. Cir. 2005) (citing Vitronics, 90 F.3d at 1582).

Further, the Plaintiff's definition of tray is not totally alien; there is extrinsic evidence to support it. One source defines a tray as "a removable receptacle . . . in a cabinet, box, trunk, or the like, sometimes forming a drawer." Random House Dictionary (unabridged ed. 2006), Dictionary.com, http://dictionary.reference.com/browse/tray (Last visited October 10, 2007). One can envision the tray apparatus of the '178 patent "forming a drawer" inside of which the computer terminal could sit.
